As was stated last week, advantage should be taken of favourable weather like the present for digging up Potatoes, Carrots, Parsnips, Beet-root, &c., where these are ready for lifting, which will be indicated, in the case of Potatoes, by the haulm becoming withered, and the tubers parting readily from the root. These crops, when got up during dry weather, and stored away in a dry state, not only keep much better, but the ground is not injured by the operation of lifting, which is the case when they are taken up in wet weather, especially in stiff clayey soils. In various parts of the country it is customary to put Potatoes in some convenient place, and after covering them with straw, a layer of earth is thrown over them sufficiently thick to keep out frost; but the best method, perhaps, for a cottager, is to store them up in a dry dark shed or cellar, where they will be secure from frost, and where they may be turned over occasionally when they begin to sprout. Carrots, Parsnips, and Beet-root keep well packed in sand or ashes in a dry room or cellar. A friend writes, "I choose a sunny day in October for taking up these roots, which I allow to remain in the open air till the evening, when I house them in some dry shed or stable for three or four days, leaving the green heads attached. Previously to packing them, I cut the tops off within half an inch of the crown, and store up the roots in a dry place with alternate layers of sand. In this way they keep sound and good for many months. Care must, however, be taken to separate the bruised roots from those that are perfect, and the sand in which they are packed cannot be too dry."—*J. M'H.*

State of the Weather near London for the week ending Oct 5, 1844, as observed at the Horticultural Garden, Chiswick.

The highest temperature during the above period observed on the 9th, 1834—therm. 79°; and the lowest on the 8th, 1838—therm. 29°.

Notices to Correspondents.

Books.—*S. Tapin.*—If we think the book worth buying we will say so when we have sufficiently examined it. You will understand our silence.

Disease.—*H. S.*—We cannot say what ails your Camellia buds; insects are not to blame that we can see. The spot on your Geranium leaves is the commencement of disease, and is supposed to arise from damp in some way.

Manure.—*W. M.*—That this agent exercises a powerful influence on plants is most probable; but such an experiment as that you mention must have either been a trick or been misunderstood.

Glazed Roofs.—*C. Bl.*—We have no personal experience with these contrivances, and cannot say whether they are as warm in winter as glass, but it is said that they are. They afford quite light enough. Your pipes may run horizontally, but one must proceed from the top of the boiler, and the other from near the bottom.

Grapes.—*W. R.*—Mouldiness, and consequent decay of the berries, is occasioned by a close damp atmosphere. The best preventive is obviously a free ventilation, giving fire-heat at the same time.‖

Heating.—*P. G.*—You will not have heat enough for flues in winter. You ought to have two four-inch pipes in front. An open gutter under your bed will be enough. The boiler must be the third size above the smallest. If you can afford it, you will find it very much more convenient to heat the gutters by a separate boiler; and then a No. 2 boiler will do for the pipes, and No. 1, or the smallest that is made, for the gutters.

Horticultural Garden.—*R. P.*—When a young man has been properly recommended for admission, he receives a printed paper, stating what qualifications are expected of him. Men are not required to bring books, but knowledge.

Insects.—*W. C.*—The little parasites from Western Australia belong to the family Diploiepidæ; but we are not able to identify the species. *R.*——*E. H.*—The Caterpillars infesting your Carrot-roots are the larvæ of a Moth named Agrotis exclamationis, and if you will refer to a recent Number of this Journal, you will find their history, and the best means of eradicating them. *R.*——*A. C.*—Your Rose-beetle is Anisoplia horticola; the Pea-beetle is Bruchus granarius: *Vide* the *Gardeners' Chronicle*, vol. iii. p. 188. The Woodlice are Oniscus asellus and Armadillo vulgaris; the characters, and figures of them are given in this Journal, vol. iv. p. 356. The plant, I presume, is a Dodder; the insect feeding upon it is the Hypera nigrirostra. *R.*——*A Wiltshire Clergyman.*—It is the larva of a Sphinx called Smerinthus ocellatus, "the Eyed Hawk-moth," figured and described in "Curtis's Brit. Ent.," pl. and fol. 482. *R.*——*Ullswater.*—The grubs injuring your Grass are the offspring of Anisoplia horticola, called the May-bug, which attacked the Roses last May and June. The rooks and starlings will clear them off in the spring, which is the principal check upon their increase. *R.*——*Jasper Stokes.*—We wish we could impress upon our Correspondents the necessity of transmitting perfect specimens; those you sent were so mutilated by the post, that it was impossible to determine the name of the Bee or of the other fly, which belongs to the Genus Helophilus; they are abundant in the autumn, but in no way detrimental to Bee-hives that we are aware of. *R.*——*Z.*—Pouring boiling water down close to the base of the frames will kill the Woodlice; they will congregate under bricks and tiles laid in the frame, and may be thus easily collected, but the best remedy is to put a toad in with the Melon-plants. *R.*——*Rusticus.*—We have long entertained your opinion as to the evils arising from the cropping of land. No doubt that insects become more firmly established where their peculiar food never fails them. It is also, I believe, ascertained that nitrate of soda, ammonia, &c., will cause certain noxious insects to desert land, and such has often been intimated in our Essays; but to what extent it is for the practical cultivator to determine. *R.*—*M. A.*—No doubt the larvæ of the Fern-fly (Anisoplia horticola), are destroying your Grass-turf at this time, and as we are writing an article upon the subject, we hope next week to give you and *Ullswater* all the information we have collected. *R.*——*Guichenot.*—The spiders' eggs are inclosed in a cottony ball in the autumn, and hatch in the spring. *R.*

Late Dahlia Show.—*G. M.*—We will have nothing to do with the person of whose conduct you complain. If your statement is correct, you were ill treated; but you should not have exposed yourself to it. Why do you come in contact with such people?

Mildew.—*A. M. S.*—Your Rose is attacked by the common white mildew. Washing well with lime-water has been recommended, but we can hardly promise you much success. You had better cut off the worst parts and burn them, and then you will not find your plants much the worse next year. The cause of its appearance has no doubt been the very dry weather, which has stunted the growth of the Rose, and enabled this parasite to take possession of it.

Names of Fruits.—*John Smith.*—Those at present ascertained are—1, 12, Rymer; 6, Christie's Pippin; 7, Norfolk Beaufin; 8, Kirke's Lord Nelson; 9, Kentish Codlin; 10, Bedfordshire Foundling; 14, Keswick Codlin; 15, Hollandbury; 16, Nonsuch; 17, Kerry Pippin; 19, Stagg's Nonpareil; 20, Wormsley Pippin; 21, Dutch Mignonne; 23, Spice; 24, Cornish Gilliflower; 26, Poire Figue; 27, 40, Beurré Diel; 28, Figue de Naples; 29, 43, Autumn Bergamot; 31, Black Achan; 32, 48, Beurré d'Aremberg; 33, Beurré Bosc; 34, Flemish Beauty; 35, Worthless; 36, Spanish Bon Chrétien; 37, Bon Chrétien Fondante; 38, Easter Bergamot; 39, Winter Nelis; 41, Glout Morceau; 42, Beurré de Capiaumont; 45, Beurré Bosc; 46, 47, Easter Beurré.‖——*R. T. C.*—2, Calebasse; 3, Doyenné Blanc; 5, Passe Colmar; 7, St. Germain; 8, Worthless; 9, Brown Beurre; 1, 2, 8, Alexander; 3, Blenheim Pippin; 4, Dumelow's Seedling; 9, Fearn's Pippin; 10, 12, Minchall Crab; 11, Golden Pippin; 14, Autumn Pearmain; 15, 20, Hollandbury; 16, Easter Pippin or French Crab; 17, London Pippin; 18, Bedfordshire Foundling; 19, Sops of Wine; 22, Golden Reinette; 24, Worthless; 25, Norfolk Beaufin; 28, Boston Russet; 29, Gloria Mundi; 30, Downton; 31, Dutch Mignonne, 32, Gravenstein. The fruit of Gansel's Bergamot grown on the coping of the wall is very handsome.‖——*R. D.*—20, Franklin's Golden Pippin; 30, Gansel's Bergamot; 40, Crassane; 50, Old Colmar.‖——*Robert Culbertson.*—Beurré de Capiaumont.¶——*A Constant Reader.*—1, Beurré Rance; 50, 51, 52, Beurré d'Aremberg; 53, Williams's Bon Chrétien; 54, Beurré d'Angleterre; 55, Colmar; 47, Jalousie. Apples—52 appears to be the Golden Reinette; 82, certainly Kerry Pippin.‖——*A Young Beginner.*—1, Dutch Mignonne; 3, Cockle Pippin; 4, Salopian; 5, Kirke's Lord Nelson; 6, Rhode Island Greening; 7, Court of Wick; 8, Golden Reinette; 9, Dutch Mignonne; 16, White Winter Calville; 7, 24, Yorkshire Greening; 19, Wormsley Pippin; 32, Norfolk Beaufin; 33, Blenheim Pippin; 34, Newbold's Duke of York. The others are doubtful in their present state.‖——*S. G.*—1, Flat Nonpareil; 2, Norfolk Beaufin; 4, Gravenstein; 6, 13, Hughe's Golden Pippin; 8, Hawthornden; 10, 16, King of the Pippins; 13, Ord; 14, Alfriston; 15, London Pippin; 18, Wyker Pippin; 21, Blenheim Pippin; 22, Syke House Russet; 23, Old Nonpareil; 24, Court of Wick; 25, Downton; 26, Scarlet Crofton; 28, Easter Pippin or French Crab; 31, Dumelow's Seedling; 32, Cockle Pippin; 34, Malden's Blush; 36, Cockle Pippin; 37, Minchall Crab; 42, Court-pendu Plat. Pears; 43, decayed; 44, Marie Louise.‖——*John Baker.*—The Pear, known in Herefordshire by the name of the Yellow Pear, appears to be the Summer Bon Chrétien. The long cylindrical, probably cider Apple, is not known.‖

Names of Plants.—*Swansea.*—Catasetum Russellianum.——*F. Meares.*—Nicandra physaloides.——*Querque, &c.*—Our specimen for the history of which see our vol. for 1843, p. 55.——*D. Judd.*—Some kind of Marvel of Peru.——*Clerimus.*—Either a variety of Fuchsia thymifolia, or a cross between it and F. microphylla.——*J. P. S. S.*—Diplacus tenuifolia.——*J. and T. Goode.*—Ruheveria secunda. The Passiflora you is not much house-room.——*A. B. C.*—1, Loasa lateritia; 2, some Calyclodon, not determinable for want of leaves.——*J. Crocker.*—Mimulus latifolia, and some Desmodium.——*Peter Macdonald.*—Rhizomorpha medullaris.——*Wood-House.*—Lucombe Oak.¶——*A Subscriber.*—Quercus ægilops; the other perhaps an Aloysia.——*F. W.*—You have alluded to. We cannot waste time in puzzling out the names of fragments of Cryptogamic plants having nothing to do with gardening. It is some Cladonia.——*A Subscriber.*—Some Celsia.

New Holland Cedar.—*Querens.*—The wood called by this name, which looks like soft mahogany, and is become fashionable in pewing of churches and chapels, is produced by Flindersia australis, or some such plant.

Pears.—*Tovey.*—When Pears separate so very readily from the tree, they require to be gathered. The variety, Bacon's Incomparable, will become mature in the course of three months after gathering.‖——*B. S.*—Marie Louise is a good dessert pear to plant as a standard.‖

Pelargoniums.—*William Crow.*—We see nothing the matter with your leaves. They are getting a little yellow towards winter, that is all. Give them in winter as low a temperature as you can, so as to be sure that frost does not touch them, say 38°. A little frost will not hurt Rhododendron arboreum, but it is better without it; house it now; pot it in one part loam, one sliver sand, and three parts peat, mixed with a little cow-dung. We have not tried Potter's guano for such things.——*A. Riall, &c.*—All the treatment which Pelargoniums for planting out in spring require during winter, is to store them up, four or five plants together, in pots or boxes. They may be put into almost any kind of soil in a rather dry state, and placed under a greenhouse stage or in any other place where they may have a little light, and be kept dry and free from frost.‡

Pines.—*Guichenot.*—A few years since, the French knew nothing of Pine-growing; but now they cultivate the fruit abundantly for the Paris market. Versailles Pine-growing is excellent, and has been formerly described in our columns. Their Cayennes have weighed 12lbs.

Plantains.—*Baigus.*—Incessantly annoy them by cutting off their heads, and die they must. But if you are negligent, and give them breathing time, they will spring up again, and laugh at your irregular efforts. Some people put salt on them when wounded, and it is not a bad plan. As to the holes left by cutting them up—why, fill the holes up again. If that little labour alarms you, it is useless to think of opposing such a troublesome, but not formidable enemy.

Potatoes.—*Anon.*—The best mode of storing Potatoes, where quantities are required to be occasionally taken out for use during winter, is to form them into a long ridge, from north to south, covered well with earth, and in proceeding make a few partitions with soil. When the haulm is withered Potatoes may be taken up.‖

Potter's Guano.—*Anon.*—This may be applied to a kitchen garden, at the rate of 3 lbs. or 4 lbs. per rod. If this quantity be diluted in 50 gallons of water, a more extensive diffusion of the manure throughout the soil will be insured.‖

Rock Plants.—*A Lady.*—The following are suitable shrubs for planting on rockwork:—Cotoneaster microphylla and marginata, Arbutus uva ursi, Berberis empetrifolia, Aquifolium and glumacea, Cistus and Hallianthemums, Pyracantha, Juniperus nana and prostrata, Cytisus purpureus, Daphne Cneorum, Hardy Heaths, Genista triquetra and sagittalis, Vinca major and minor. Of *Herbaceous* plants procure the following:—Saxifrages, Pentstemons, Statice tatarica, latifolia, Gmelini, and bellidifolia, Aquilegia fragrans, glandulosa and canadensis, Campanula grandis, pulla, and versicolor, Dianthus superbus, and others, Gentiana acaulis and asclepiadea, Phlox procumbens, nivalis, and setacea, Œnothera speciosa, macrocarpa, and Fraseri, Iberis sempervirens, Geranium ibericum and sanguineum, Anemone vitifolia, Alyssum saxatile; Ferns and Sedums, Crocuses, Scillas, Narcissi, and other bulbs, for flowering in the spring.¶

Seedlings.—*C. R. S.*—Double Eschscholtzias are very uncommon. The first raised in this country was obtained in Mrs. Marryatt's garden at Wimbledon. Yours is much superior. We should save the seed, and try to improve the variety.

Strawberries.—*W. H.*—We should not trust such plants for early forcing. It is doubtful whether they will have time to re-organise flower buds, (after you have destroyed what are now showing), before the early months of spring. They may; but it is hardly probable.

Toads.—*C. N. B.*—The advice to keep toads in your garden is good. They are most useful and harmless though much-calumniated creatures. Just place one in your hand and look at its beautiful eyes. Poor things! they have no poison in them, and will not hurt your dog if he should venture to eat them; but we hope he is better taught than that.

Tobacco.—*G. B.*—You cannot legally grow Tobacco for the purpose mentioned. If, however, only a very trifling quantity is grown, and *bonâ fide* used as stated, it is not probable that any notice would be taken of it. *W.*

Vines.—*Rusticus.*—Your inquiry demands a longer answer than we have room for this week.

Vine-Borderers.—*Appeto.*—We cannot give you further information on this subject. If you consult Mr. Hoare's book you will find his mode of proceeding fully detailed.

Water-plants.—*A Lady.*—The following are suitable for a pond:—*Nymphæa alba*, Nuphar lutea and advena, Butomus umbellatus; Menyanthes trifoliata and nymphoides, the double variety of Sagittaria latifolia, Hydrocharis morsus-ranæ, Aponogeton distachyon, and Alisma plantago.¶

Miscellaneous.—*H. H.*—If you dip your woollen cloth in a weak solution of pyrolignite of iron (the brown liquor of Lancashire), or into drying oil, it will last the longer for the application.——*A Subscriber.*—Your suggestion has been sent to Mr. Paxton and Mr. Hutchinson.——*Orchis.*—Treat your Sobralia exactly like the tender Cypripediums.—*J. Tyre.*—We do not think you can keep Brugmansias in the open border during winter, unless you incur considerable expense. Provided the ground is thoroughly well drained, you might perhaps effect it by thatching them very thickly with straw, brought to the form of a cone. Leycesteria formosa propagates freely by cuttings, layers, or seeds. It is seldom advisable to place dung below the roots of trees; as to stones above them, what are they to do of either good or harm, unless the trees are newly planted? when, no doubt, if heavy enough, they keep trees firmly in their place.——*A. B. C.*—Phaius maculatus is a pretty good plant. We have not often seen it in flower. It is perfectly well known that Kalmia latifolia is poisonous.——*H. T.*—If you watch our Weekly Calendar of Operations you will obtain full information on all such points.‡——*D. S. G.*—Full information respecting the destruction of Woodlice is given at p. 356, 1844.‡——*Philobotanicus.*—Many thanks for the specimens of Xenodochus, which is new to us. No doubt the White Elder will take on the Black; but it would be necessary to graft while the wood is quite soft. An E.N.E. aspect is not the best for fruit-trees; the most likely to succeed will be the Glout Morceau and Marie Louise Pears. Or you might get Peach Apricots on that which is well sheltered.——*J. W. T.*—If your stone is not waterproof you may make it so, by covering it with a thin coating of Portland or even Roman cement. But the porous quality of your stone covers for flues is, perhaps, no great disadvantage, for the water is probably not lost, it is only absorbed by the stone. If, however, it really does run through the stone, and is not merely absorbed, then you must go to cement for assistance.

SEEDLING FLOWERS.

Dahlias.—*W. C. D.*—Your flower is fine in its general form, deep, with the centre well up; the petals also are of good form and substance; but there is an irregularity in the centre of the flower which will prevent its being classed as a first-rate variety.‡

Verbenas.—*H. H. H.*—The best varieties in your batch of seedlings are 1 and 3, the former a bright rosy vermilion, the latter a deep lilac, the colours being very decided; but in these the flowers appear to want fatness. The scarlet is good in colour, but small, and not equal to many in cultivation. The remainder want decision of colour.‡

CHEAP AND DURABLE ROOFING.

BY HER MAJESTY'S ROYAL LETTERS PATENT.

TO GARDENERS, NURSERYMEN, AND OTHERS.

F. M'NEILL & CO., of Lamb's Buildings, Bunhill-row, London, Manufacturers, and only Patentees of IMPROVED PATENT ASPHALTED FELT, for Roofing Houses, Sheds, Verandahs, &c., and for Protecting Plants, and Covering Garden Frames, beg to call the attention of Gardeners and others to their superior article, which has been exhibited at the Great Agricultural Shows of England, Scotland, and Ireland, and OBTAINED the PRIZE for being the best and cheapest article for roofing, &c. It has been tested in the gardens of several noblemen and gentlemen in the neighbourhood of London, and in different parts of the country, to whom reference can be made. The Felt is impervious to rain, snow, and frost, and a non-conductor of heat and sound. Its advantages are Lightness, Warmth, Durability, and Economy.—Price ONLY ONE PENNY PER SQUARE FOOT.

Samples, with directions for laying on, and testimonials as to its merits, sent free to any part of the town or country.—Patent Felt Works, Lamb's Buildings, Bunhill-row, London.

The Agricultural Gazette.

SATURDAY, OCTOBER 5, 1844.

MEETINGS FOR THE TWO FOLLOWING WEEKS.
THURSDAY, Oct. 10—Agricultural Imp. Soc. of Ireland.
THURSDAY, Oct. 17—Agricultural Imp. Soc. of Ireland.
FARMERS' CLUBS.
Oct. 8—Abergavenny. | Oct. 9—Monmouth.

THE BARLEY CROP OF THE PRESENT YEAR is decidedly a failure in quality throughout the greatest part of the country. In ordinary seasons there is no grain-crop which requires more judicious management. Of all the cereal Grasses its straw is the softest and the most succulent, and its grain the most liable to sprout. Mismanagement of the soil prepared for its growth, or neglect of the season, affects not merely its quantity, but also its marketable value. This is accounted for by the fact that the best samples of Barley are made into malt, and by the necessity which therefore exists that the soil prepared for it should be in such a condition as to allow the seed to germinate immediately, and at one time, so that it may ripen uniformly and together, and that thus, during the process of malting, it may all sprout at one time.

During the past *extraordinary* season, however, many farmers have been unable to secure these advantages; and the consequence is, that in some districts, especially in the north of England, though the other grain-crops have been secured weeks ago, we find large flats of Barley yet uncut. In some fields we have patches in every stage of progression from bloom to ripeness; in others, plants of every age are mingled together—the young shoots of summer overtopping the ears which have attained maturity; and these are unfailing indications of an inferior quality of produce—of a coarse, light, uneven sample.

It is impossible to notice these peculiarities without inquiring into their cause, and attempting to ascertain whether or not it was possible to have prevented them. It may be said that "after-wit is dearly bought," but it is not the less valuable for that: it may even be cheap, if it should induce us on a future occasion to avoid the rock on which we may previously have split. The cause of the late and unevenly ripe crops of Barley, it will at once be said, was the extraordinary droughty weather which we experienced before and after seed-time. For instance, many lands—owing to the crop of Turnips not being fed off until spring—had not the advantage of being ploughed in time to allow the frosts to act upon the soil, and thus the necessary fine tilth could not be obtained; and in waiting for rain to enable the clods to be broken up, the proper season of sowing was lost. Elsewhere, again, the crop of Turnips may have been eaten by sheep in pretty good time, and the land ploughed in February, but in consequence of the sheep having been folded on some portions in wet weather, the whole surface could not be brought to an even tilth—the plots where the Turnips had been consumed in wet weather were full of clods, upon which harrow and roller, without the aid of rain, had no effect, while the rest of it was already fit for the reception of the seed. Under these circumstances the sowing was delayed in expectation of rain, but before patience failed the right season was past. The consequence of this proceeding was an irregular germination of the seed, resulting in an unevenly ripening crop. In other cases, under like circumstances, the period of sowing was delayed still longer—delayed, in fact, until a great portion of the moisture escaped from those parts which were properly pulverised—so that when the seed was sown *no plants* at all appeared on the rough portions for several weeks, while only a *tithe* of the seed on the finest plots germinated in proper course. Where this was the case fresh plants continued to appear week after week even till midsummer, and gradually filled up the ground, the roughest plots being of course latest. In such fields at the present moment, the crop consists of plants of every age and every colour, and must produce a sample made up of various qualities of grain.

Such explanations as these will be generally given of the circumstances to which we call attention, and we do not hesitate in vouching for their truth. Indeed, many cases have come under our own observation, where the loss of a season has arisen from a single patch—say an acre—or a few furrows in one field being full of clods and stubborn in texture: the farmer has waited on account of this patch, till all necessary moisture had evaporated. While thus we acknowledge that the nature of the season was the *primary* and *nominal* cause of these evil effects upon the crop, it must, however, be contended, that as it was by no means impossible to have prevented such effects, this was not the *real* and blameworthy cause. Means exist by which the evil effects of the season might have been counteracted—means which have in many cases been successfully employed, and which may, in future, be still more extensively used. The true cause of the failure is our own imperfect cultivation; and it is a matter of duty to call attention to that in which our ordinary practice has been inadequate to meet the exigencies of the season. It may be premised that many crops of fine Barley have been obtained during the present year, without any particular care or management. For instance, upon deep sandy soils, and in cases where a winter ploughing was given, and the surface rolled and sown early—or when a fine tilth could be had by harrowing and rolling, and sowing immediately after the plough—a proper season was obtained, and vegetation progressed favourably. Upon all strong soils, however, and upon soils which had been trodden in wet weather, or which, owing to the Turnip crop having been taken off in spring, had been thoroughly affected by the drought, the ordinary operations of tillage were ineffectual. In these cases it was that our cultivation was imperfect; extra difficulties were not met by extra means. Instead of waiting for rain to pulverise our soils, proper mechanical means should have been used to accomplish this all-important object. For this purpose, there can be no question the BEVERLEY CLOD-CRUSHER would in all cases have been sufficient. By its aid, indeed, we have seen many hundreds of acres prepared at a time when the implements usually employed were useless; and on all these lands the seed was deposited, and the grain has been secured in proper season.

For this implement we are indebted to the ingenuity of Mr. Crosskill, of Beverley. It consists of 28 serrated wheels or rollers, each 2½ feet in diameter, and placed upon a round axle 6 feet wide. The roller parts or wheels act independently of each other upon the axle, and in turning produce a self-cleaning movement at the same time that they crush the hardest clods, and convert them into a fine mould. Further description is unnecessary, as the implement is already well known, though far from being sufficiently appreciated. The pages of the Journal of the Royal Agricultural Society have borne ample testimony to its many uses and general efficacy in the cultivation of all sorts of soil. Our aim, however, is merely to call attention to its use as a pulveriser, and as a means of enabling us to prepare the most stubborn soils, and to make sure of a seed-time in the driest weather.

By its operation many were enabled last spring to obtain a fine tilth, to preserve the moisture of the seed-bed, and sow their Barley in due course upon soils which otherwise could not have been prepared for the crop till midsummer; we may therefore rely upon it as a most effective means of preventing those disastrous delays to which we have called attention. With an agent like this in our power, a season like the past is not necessarily fatal to the prospects of the crop; with such means at command, it was possible, in a great measure, to have prevented the results which we have now to regret.

Why, indeed, should we wait for a shower?—wait, too, for days or weeks, or, as last year, for months, to effect that which we can, by mechanical means, accomplish in a few hours. To wait for the clods to fall in pieces when we have the means of breaking them at any time ourselves, is calling upon the heavens to assist us without putting our own shoulders to the wheel. We no longer wait for the winds to waft us from shore to shore. When, indeed, they are favourable, we make use of them; but when otherwise, we employ a power which can move in the face of them. And it should be the object of the intelligent farmer also to contrive operations, and to provide means which will enable him to overcome the natural difficulties he may meet with. The fable of the farmer who delayed his harvest for one week, in the expectation that his neighbours would lend him their help; and for another, when his neighbours failed to come, in the hope that his friends and relations would come to his assistance; and who, on these also forgetting him, was at last compelled to do the work himself, has a moral which, enforced as it is by the experience of the present year, will, it is hoped, induce us for the future to depend less upon the "chapter of accidents," and more upon ourselves. The gods help those who help themselves.—*H.*

ON the 11th of April, 1843, a Committee was appointed by the House of Commons, on the motion of the Hon. W. Cowper, "to inquire into the RESULTS OF THE ALLOTMENT SYSTEM, and into the propriety of setting apart a portion of all waste lands which shall be inclosed by Act of Parliament, or of any lands which, under any Inclosure Act, shall have been appropriated to the benefit of the poor, to be let out in small allotments to the labouring poor of the district, and also to inquire into the best mode of effecting the same."

The Committee thus appointed presented a Report to the House, based on the evidence of numerous and competent witnesses. The evidence of Wm. Miles, Esq., M.P., and the Report of the Committee, were published in the "Labourers' Friend Magazine;" and a few extracts from these, in addition to the facts which we have already adduced, will amply sustain our opinion of the benefits which the introduction of the Allotment System is calculated to confer on the labourer.

Mr. Miles says:—"I first of all commenced taking any interest in allotments about the year 1828, when I was resident in Nottinghamshire, on a clayey soil, in the parish of Caunton; there were about eight acres, or eight acres and a half, which had been left for the benefit of the parish; . . . I called the attention of some of the parishioners to it; we called a vestry meeting, and, under the 59th of Geo. III., we offered to let this land in allotments to the poor. We divided it into allotments of about a rood to each individual. I was resident in the county, I think, six years afterwards, and I can state from my own experience that, though the soil was a stiff clay, and certainly the last of all soils that I should have taken for allotment gardens, by the assiduity and labour of those poor people it was brought to bear the very best of vegetables: good crops of Potatoes, and Onions, and other vegetables. And I was informed by those who had the allotments, taking a good deal of interest, and going frequently to the gardens and talking to the people, that it was one of the greatest benefits that ever befel the inhabitants of Caunton that the ground left for parochial purposes was allotted to the poorer inhabitants of the place."

Mr. Miles afterwards states:—About six years after this I went to reside in Gloucestershire, where I am at present resident; I then prevailed upon my father to allow me to give, in three different parishes, allotments to the labouring poor. I invariably chose the very best land I could, and that nearest to their own dwellings. I allotted in that way, in the three parishes, land to about one hundred persons altogether; and I can state that invariably in all those places in which those allotments have been so given, the benefits produced to the poor have been something perfectly extraordinary; you have only to go into one of those gardens, and take the chance of any person who may be working there, however late or early, and you will be exceedingly interested, first of all in his manner of addressing you, and at the same time with the benefits which invariably, he says, have resulted from those allotments of ground to himself and to his family. As I understood it was the wish of the Committee, when last I appeared here, that I should state what was the result of the benefits to the poor man as nearly as I could, I went to the garden of one of the first men I saw; I inquired what benefits had accrued to him as to the sale of vegetables, and, at the same time, as to supplying his family with food from his allotment. He stated to me that he occupied a rood of land; that for that rood he paid 1*l.* a year; that he had sold Onions last year to the value of 24*s.*; Carrots to the value of 8*s.*; and that his wife had sold Gooseberries and Currants to the value of 2*s.* 6*d.*; that he had a wife and five children, and that he had provided them from the allotment with every description of culinary vegetable, with all their Potatoes; and had only purchased for the year one sack of Potatoes for the whole consumption of the family; at the same time I should mention that I never go into those gardens but thanks are given to me for what has been done." The 1*l.* per rood, rent included, tithes and rates.

The first branch of inquiry in which the Committee engaged was, "the effect of the arrangements under which the labouring classes are now enabled to hold and cultivate land on their own account," and the Report states:—"The evidence received upon the first branch of their inquiry has been of uniform tenor, and has led them to conclude that the tenancy of land under the garden allotment system is a powerful means of bettering the condition of those classes who depend for livelihood upon their manual labour, whether in manufacturing or agricultural employment; and it has this peculiar merit, that

its benefits are not obtained at the expense of any other class, nor accompanied by any corresponding disadvantage."

After recommending certain regulations to be observed in carrying out the system—all or some of which we may hereafter comment upon—the Committee proceeds to say—"Under these arrangements the system of garden-allotments has proved an unmixed good. It has increased the produce and enlarged the general stock of labour to be expended on the soil. It has enabled the labouring man to turn his leisure moments to profitable account, in raising wholesome food for his family, a rood of land frequently producing vegetables enough for six months' consumption. It has also supplied sound industrial training for the children, under the parents' eye.

"Many striking instances have been stated to your Committee where the possession of an allotment has been the means of reclaiming the criminal, reforming the dissolute, and of changing the whole moral character and conduct." It appears that the holding of land directly from the landlord raises the position of the working-man in his own estimation, and gives him a feeling of independence and self-respect. It gives him a stake in the country, and places him in the class which has something to lose. It partly supplies that deficiency of innocent amusement and rational recreation which weighs so peculiarly upon the lower classes of this country, and which must be counted among the causes which lead to the prevalence of crime. The field-garden has attractions for the working-man strong enough to relieve the monotony of a life of hired toil, and to dispel the listlessness and discontent which are often its accompaniments. It withdraws him from a dependence for amusement on the society of the alehouse. It gives him something which he may call his own; and as its value depends upon his own exertions, it prompts him to the exercise of self-control, and leads him to look on from the present towards the future. It furnishes him with an interest in life to stimulate his faculties, to occupy his mind, and to inspire him with hope; and it becomes a powerful inducement to abstain from any of those offences which would lead to the forfeiture of this valued possession. Mr. Martin stated, "That of 8000 heads of families holding allotments in Kent, not one was committed for any offence during the years 1841 and 1842; that in the parish of Hadlow there were 35 commitments in 1835. The allotment system was introduced in 1836, and in the following year, 1837, the commitments were reduced to 1." "Since that we have had among the tenants of the Society about 1.5 of those who were in prison in 1835, and there has been no cause of complaint against them since we have had them. Since the year 1837 there has been but one commitment from among the holders of allotments."

"It does not appear to your Committee that these important benefits are purchased at the expense of any other interest. All the witnesses were unanimous as to the punctuality with which the rents of those allotments which are under proper management are paid, and no more trouble seems to have been involved in collecting these than any other rents; frequently, indeed, there is less. Numerous instances have been mentioned where the produce of the allotment has been effectual in keeping men from applying for parochial relief; and it may be safely assumed that a practice which diminishes the poverty of the labouring class, and promotes their good conduct, cannot but be beneficial to the community at large. It has likewise had a peculiarly good effect upon the relations between the landowner and his cottage tenants; increasing his acquaintance and interest in their circumstances, and exciting in them more thankfulness and respect."

To infuse a healthy prosperity into every branch of our industry, and to widen and deepen the channels of remunerative labour, would be at once the universal and effective remedy for the destitution of the labourer. But if this were accomplished, and the labourer left an uneducated and an untrained man, extravagance and dissipation would be likely to appear where the fruits should be comfort and independence. Every improving influence which a sound religious and intellectual education brings to bear on the character of the labourer, and every improving influence which can be laid in his pathway through life, should be sedulously employed. It has been well proved that the allotment system affords such an influence, and the Report from which we have quoted represents that influence in a strong light. In the prosperity of the labourer the allotment system would have a good moral effect, but in his adversity its services become still more important. When we consider the present condition of the labourer, the comforts which an allotment will bring to his cottage and his hearth, the improvement which it will accomplish in his character as a man, and his value as a workman, in the feelings and dispositions of himself and his family; when we look at the increase which his industry will effect in the value of the land, and in the amount of its produce, to the advantage of the landowner and the community, as well as of himself, and to the security afforded against pauperism or criminality—all which benefits the allotment is proved to confer—we hail the allotment system as a powerful palliative of existing evils, and a prolific source of future good: we hail the system as the labourers' friend in prosperity or depression, and its introduction as a measure fraught with substantial advantage to society at large.—*F.*

ON LIME AS A MANURE.

I know of no manure of more importance to the farmer, when properly applied, than lime; but it is as undeniable a fact that the action of no manure is less understood. Its importance has been so much descanted upon, and the proofs of its usefulness so clearly demonstrated, that it is scarcely to be wondered at that the farmer should consider it as a specific for all the wants of his land. Indeed it is considered by many to act as a universal medicine, to be administered whether the field require it or not. I have known cases where it was to supersede draining, farm-yard manure, and bones; and have seen its use so abused, in the neighbourhood of Winfield, as to cause the cessation of growth. I recollect meeting with a farmer, in the spring of this year, who was applying three cartloads of quicklime to an acre of marsh meadow land, in order to kill the reeds, and found it impossible to persuade him that there could be no cure for his land but thorough drainage. We shall endeavour to show when lime is useful to land, and in which cases it would be hurtful.

We only know of one plant, the Salsola soda, which does not contain lime in combination with organic acids. This fact alone is sufficient to account for its presence in all fertile soils, and for the necessity of supplying such lands with lime as may be deficient in it. Schroeder found 33·75 grains of carbonate of lime in the ashes of 32 oz. of the grain of Oats. In soils lime generally exists as sulphate (gypsum), phosphate (bones), carbonate (chalk), and humate, the latter more especially in peaty soils. To lands where lime is deficient it should be applied in its caustic state, as quicklime, and that for the following reasons:—1. Because it would be too expensive to supply the deficiency in the shape of carbonate of lime, where it has to be brought from any distance, inasmuch as chalk contains 45 per cent. of carbonic acid, an amount nearly equal to half the carriage, without contributing any serviceable matter. 2. If the land be rich in organic matter, as in peaty soils, the express purpose of applying lime in a caustic state is to destroy the vegetable matter—an effect produced by lime in the same manner as it is effected by burning it. 3. It destroys coarse Grasses, as Couch-grass, and when mixed with the scourings of ditches, and coals of worthless Grass, makes an excellent top-dressing for Grass lands. 4. It kills seeds and insects, for which reason it is highly important to mix newly-upturned clay, intended for agricultural purposes, with quicklime, in order to destroy the seeds. 5. If the land produces a sour Grass, lime will neutralise the acids, and render the herbage sweet and palatable. 6. Its capability of solution; and lastly, the great chemical effect it produces on the inorganic ingredients of the soil, in rendering potash soluble, and converting poisonous proto-sulphate of iron (green vitriol) into an innocious compound. These are the most important reasons. The addition of quicklime proves of most importance on heavy clays, which it renders more porous and friable. Where lime is wanting in the soil the fertility of the soil is increased, and superior crops produced by its application. The time for applying lime is not immaterial. It should never be placed on land immediately after manuring with a compound containing ammonia, as farm-yard manure, guano, and soot, as it would expel the ammonia. Lime and dung should never be heaped together, nor should land be dunged till about two months after it has been limed. If the chief purpose for which lime is applied be to destroy vegetable matter, the land should be dry. The immediate effects will be slow, but a little rain will produce the effect far more quickly than if the soil be very wet. In reclaiming lands this should be well recollected. If, however, it be our object to prepare land before the sowing of a crop, the liming should take place in autumn, because the effects of lime are not instantaneous. Supposing a piece of arable land be overrun with Couch-grass, which we have not been able to eradicate, and taking for granted such land has not been limed, we should treat it thus:—The land should be covered immediately after harvest with a thin layer of quicklime, spread out as evenly as possible; then it should be ploughed in, laying one furrow each way, on the unploughed land, and let it lie till February; then plough the whole in a contrary direction, leaving the land lying in the heaps, as it will then do till after spring sowing, when the lime and the weather will have taken such effect on it as to make what is left of the Couch easily got out by using a large harrow instead of a scuffler, which cuts the Couch into small pieces. This method is mentioned by Hilly, and although he does not propose the use of lime, which I think will materially quicken and complete the process. It is not well to apply large quantities of lime at a time, intended to last for a number of years, but it should be our endeavour to put the land into such a condition as to be able to afford sufficient lime for plants, and to keep up this quantity either by small yearly additions, or by larger additions every four or five years; otherwise considerable loss takes place. Caustic and slaked lime are soluble in water; a large quantity will therefore be removed from the reach of the roots of plants by falling rains. Much of it will again be brought up by the plough, but much will go beyond its reach. If the land is not drained the loss will be greater than otherwise. It is true that lime does not remain long either in its causticity or as slaked lime, but is speedily converted into chalk. But rain-water always contains carbonic acid, which dissolves the carbonate (as bicarbonate), and removes it from the soil. Supposing the land to be quite wanting in lime, a larger quantity than usual may be supplied; in such a case, 30 bushels of quicklime, well mixed with the upper soil, would be ample, but more than this is generally applied without injury. The waste should be annually supplied; the fertility of the soil will thus be more effectually kept up than by the general methods. The quicklime should be broken as much as possible, evenly spread over the land, and intimately mixed with the upper soil.

The effects produced by an overdose of lime are sometimes irreparable. On wet and undrained clays an overdose of quick lime causes a chemical combination of the lime with sand, clay, and water. A species of mortar is formed, and the land hardens, so that neither the roots of plants nor rain water can penetrate it. Dry and sandy soils are rendered too porous. Supposing, however, that such effects do not take place, it is certain that the action of lime on the inorganic ingredients of a soil is to render soluble many salts well adapted for the nutriment of plants. It may, therefore, call forth increased fertility at first, but unless the land be plentifully manured it will be miserably impoverished. It must be recollected that lime is no substitute for any other manure, and that farmyard manure must be used at proper intervals; for because lime is required by plants, it does not follow that they can thrive without ammonia or potash. An overdose of lime may call forth another class of weeds at the expense of those which it destroys. A fertile soil should contain at least one-fourth per cent. of lime; it may, however, contain more.

As at the present day much fraud is practised on manures, it may be in place to state the different adulterations of lime, and the methods of detecting them. It is often mixed with carbonate of lime or imperfectly burnt material; in which cases strong effervescence will ensue, if a piece be thrown into a wine-glass filled with diluted oil of vitriol. It is better to slake the lime first.

Water is often poured on lime, which, if added in large quantities, slakes it; it would then not retain its shape, but fall to powder. The best method of judging of the amount of water and carbonic acid is to weigh a piece of the article, then heat it to redness, allow it to cool, and re-weigh it; the loss indicates the amount of impurities. The farmer should therefore burn his own lime, if it is to be had on the spot.—*Albert J. Barnays, Derby.*

SKETCHES OF EAST LOTHIAN HUSBANDRY.

Cultivation of Crops.—The crops commonly cultivated in this county are Wheat, Barley, Oats, Beans, Potatoes, Turnips, Peas, and Vetches. Those occasionally or but partially grown are Carrots, Mangold Wurzel, Rape, and Flax.

Wheat is the staple produce of East Lothian, and to the production of it the soil of the greater part of the county is well adapted. It is difficult to ascertain with precision the extent of land usually occupied with Wheat, or the quantity annually produced, but both are so considerable as to render everything connected with the cultivation of this crop of the greatest importance to the farmers.

The varieties of Wheat now most esteemed and chiefly grown are Hunter's, Hopetoun, Gregorian, and Brodie's—the two former adapted to winter, and the two latter to spring sowing. But besides these, other kinds of Wheat are occasionally cultivated, as Red Lammas, Blood Red, Hickling's, Chidam, &c. Hunter's is the most esteemed variety of white Wheat now grown in the south of Scotland; it is a winter Wheat, and may be cultivated on any kind of soil of moderate fertility. The Hunter's and Hopetoun varieties were propagated in this county, the former by the agriculturist whose name it bears, and the latter by Mr. Patrick Shirreff, late tenant-farmer at Mungoswells. Red Wheat is not much grown, and is confined almost exclusively to the more elevated parts of the county.

Wheat is sown after summer fallow, Beans, Potatoes, Peas, Vetches, Turnips, and occasionally also after Grass. Bare fallow is not considered to be in all cases the best preparation for this crop, as the young plants are very liable to be thrown out of the soil by the influence of the winter's frost, in consequence of the minute pulverisation given to it by the fallowing process. When sown after Beans, the quality of the grain is frequently superior to that grown upon naked fallow, and in consequence of the greater solidity of the land affording a rougher surface or clod after harrowing sufficiently to cover the seeds, the plants are not so liable to be disengaged from the soil by alternate frosts and thaws, as in the case of fallow or Potato land. On this account, Beans, when the land has been thoroughly cleaned by the culture given to the crop during the summer months, is accounted an excellent preparation for Wheat. As soon as the Bean crop has been removed from the field, the land is ploughed into ridges, and the Wheat-seed immediately sown; the ploughing, sowing, and harrowing operations being all performed in close succession. Experience has placed the Potato crop amongst the most suitable preparations for Wheat, both as regards the quantity and the quality of the produce. I may observe that the Clovers are seldom found to succeed well after Potatoes or Beans, at least not upon strong clay land. Wheat is now frequently sown after Turnips. The practice of

taking up and storing Swedish and common Turnips as favourable opportunities occur during the winter and early spring months, is becoming general. The leaves, as being cut from the bulb, are scattered over the surface of the land, and ploughed down immediately after the removal of the Turnips. Wheat is sometimes but not often sown upon Clover leys, as the practice is by no means a favourite one with the East Lothian farmers. There are some cases, however, in which it is expedient to grow Wheat instead of Oats after Grass, and in this case the land usually receives a partial fallowing.

Seed Wheat is invariably prepared for sowing by pickling—a process resorted to for the purpose of preventing smut. The liquid most commonly employed for this purpose is stale urine, and the process of steeping or pickling is generally as follows:—Two tubs, one of which may be larger than the other, are required for the operation. The barn floor, cart-shed, or some other suitable place, being well cleaned, the larger tub in which the seed is to be steeped is placed on an elevated stand, and the other vessel containing the urine laid alongside it on the floor. The pickling tub is then nearly filled with the grain, and the urine poured upon it with a stable pail till the tub is full. The seed is well stirred with a shovel, and after being all thoroughly moistened and allowed to remain five or ten minutes, the liquid is withdrawn through an orifice into the other vessel. The Wheat thus pickled is then laid in layers upon the floor, and a quantity of newly slacked lime, sufficient to absorb the moisture, sifted upon it while being spread on the floor. A fresh allowance of Wheat is now put into the steeping tub, and treated in a similar manner until the entire quantity to be then sown has been pickled. The seed with the lime sifted amongst it, is immediately afterwards turned over and intimately mixed; it is then conveyed in sacks to the field to be sown. No more seed is pickled at one time than what can be sown on that or the following day, as the vegetative powers of the Wheat are often materially injured, or totally destroyed, from remaining any length of time unsown. Besides stale urine, which is universally regarded as the most efficacious pickle, a solution of salt, sufficiently strong to buoy up an egg, is sometimes employed. But the principal recommendation of this steep is the facility with which it may be prepared. A solution of blue vitriol is also occasionally used as a pickle for seed Wheat.

The seed is, in the great majority of cases, sown by the hand, but the broadcast-sowing machine is also employed on many farms for the same purpose. Wheat is frequently sown in the manner styled ribbing, already adverted to. When this mode of sowing is adopted, the seed is scattered by the hand in the usual manner; but as nearly the whole of it necessarily falls into the intervals between the small drills, the plants grow up in parallel rows in the same manner as if sown by the drill-machine. The practice of ribbing in Wheat upon summer fallows is highly approved of, as a means of preventing the ejection of the young plants by the influence of the winter frosts; it is, further, almost a certain way of securing a good crop of Clover the following year.

Wheat is sown from the beginning of September to the end of March. The quantity of seed depends of course upon the time of sowing, and the quality and condition of the land. After summer fallow, two bushels per acre are deemed sufficient; and after Beans, Potatoes, or Turnips, three bushels. Old Wheat is sometimes sown in preference to the new, and in this case a less quantity of seed suffices.

The produce has been, in many instances, so high as six quarters per imperial acre, but this quantity is reckoned a great crop; four quarters per acre are frequently obtained in the low district; and many farms average 3½ quarters during a lease. Taking the average of the whole county, however, for the last few years, the produce is estimated at 2¾ quarters per statute acre. The weight of Wheat varies, according to the seasons and other circumstances, from 60 to 66 lbs. per bushel. —*T. Sullivan.*

Home Correspondence.

Manures and Drainage.—Publications on experimental or practical manurings are of much value, but there is for the most part a very material omission in such reports. I refer to the analysis of the soil, which is necessary in every such case, previously to the applications of manure. Trials of various substances are made and multiplied with great care and precision, and the results are watched and recorded with minutest attention, without any, or with only a slight reference to the constituents of the soil. Is there any one science besides Agriculture, the facts of which are thus carelessly determined? Now, let any one of these reports be read, and let the reader try the most successful experiment on his own soil. Will the result be similar? No. And why are the results dissimilar? That is a question seldom put; and the experimentalist either sits down discontented, or goes indefatigably to work with the next best manure, perhaps with equal ill success. One tries nitrate of soda on a soil within reach of sea-breezes which have for ages borne to it enough of soda, and he fails. Another carries nitrate of potash to a soil containing sufficient potash, and he fails. So it is with gypsum, and many other substances. One remark, however, may be made by the way, and that is, that appearances sometimes deceive. Some well-established facts have shown that a great increase may be made to the weight of a crop of hay, or to other crops, by a manure the effects of which do not make any great show on the ground; and on the contrary, instances of great apparent with little actual effect often occur, as when a deeper green in a plant may be produced with little benefit to the produce. Some allowance must be made for variety of seasons, but soils of great fertility and good tilth are much less exposed to injury from too dry or too wet weather than poor soils. It is true we cannot give to a poor sterile soil all the constituents of one that is fertile, without incurring an expense far beyond the profit. This, however, is unnecessary, for we know that a very small quantity of some substances will often insure a great crop, and in such cases all further applications would have been an unnecessary outlay; and so, by parity of reasoning, the extra fertilising materials in a fertile soil are frequently of no apparent use. The great object then is, that in every case of manuring being reported, an analysis of the soil be given. It is not enough to say the land is a sand, or gravel, or clay, or loam, but it is indispensable that the constituents of the soil should be minutely stated; then, and not till then, will Agriculture take its proper rank as a science. [This is, probably, sufficiently correct; but coupling together, 1st, the imperfection of our means of analysis, and the consequent impossibility of ascertaining the actual composition of the soil of a field; and, 2d, the great expense of the operation—an expense the greater in consequence of the great variability of soil even in its mineral component parts—coupling together these two considerations, we question if it be not the more economical plan for farmers, if they require them, to try the various manures each for himself on a limited scale, and then be guided by personal experience in the matter of their more extended use, rather than rest on reports of published experiments, the imperfections of which are here so accurately indicated.]—A question has been lately asked in your Journal—"What is the action of sea-salt on carbonate of lime?" In dry weather, after a high tide, little hollows may be observed on the limestone and chalk strata of rocks on the sea-coast, where the salt water has been evaporated, leaving crystals of common salt. In all these instances the rock appears more decomposed than it would have probably been if only rain-water had fallen and been dried there; but this requires to be verified.—Many able articles have been published on drainage, but nearly all of them relate to arable land. Now, a little observation will show that the draining of Grass land is of equal importance. The difference between good and bad pasture land is not so apparent as it is on land bearing a crop. Meadow land more resembles arable land, as there is a crop of hay to be made; but the bulk may be considerable in certain seasons, while the quality is of inferior value. Grass land is usually wet land made partially dry by surrounding ditches, and some open drains. It is very seldom properly drained so as to remove the stagnant water within reach of the roots of Grasses. Grass land may be classified as follows:—1st. Constantly wet on an impervious subsoil; bearing the sedges and many sub-aquatic plants which thrive in land full of stagnant water, but are of little value, and that only in the middle or latter part of summer. 2dly. Wet, but on a porous substratum, and consequently experiencing a slight circulation of air through it, by the passing away of some portion of the water with which it is charged. This land supports better Grasses, but it is so chilled by evaporation, and there is still so much stagnant water, that such land is comparatively very inferior. 3dly. Originally wet, but thoroughly drained by open or closed drains two or three feet deep. Land in this state is but seldom seen, but it generally produces the best Grasses, which are growing the greatest part of the year, and the sedges and inferior Grasses which formerly grew upon it are gradually disappearing. It is frequently objected to drainage, that there is not sufficient fall or outlet for the water. This objection is often imaginary only, and if the operator begins his work at his lowest point, and drains upward as long as he can see the water run, he will generally find fall enough. There are, however, cases where there is a fall, though it is not apparent. This is well worth attention. A stream of water runs nearly as fast at the bottom of a full channel as at the surface; it runs faster than either in the middle. Suppose an outlet to be into a full watercourse, a drain full of water leading into this full watercourse will still slowly convey the water in the drain, and the drain will receive a supply from the water in the soil which would otherwise stagnate there. Such full drains should be frequently cleared of obstructions under the surface, and the good effect will infallibly appear, even under such unfavourable circumstances. From the usually flat surface of Grass land, closed drains are not frequently made. Open drains are commonly too shallow; they should be deep enough to draw away the water beneath the surface soil, so as to render it warm and dry very soon after being wet. It will not then be injured by a wet season, nor by a dry one.—*T. P.*

Dibbling Wheat.—We live in an age when the productive powers of the land are more fully developed than they have hitherto been. Any improvements that will increase the quantity and quality of the produce, are deserving of consideration; to follow an established system, merely because our progenitors have so done, savours strongly of prejudice; agriculture, like other sciences, should keep pace with the increasing intelligence of the age. The dibbling of Wheat has recently met with encouragement; whether the practice will fully answer the expectations of its promoters, further experience will demonstrate. The following experiment, upon a small scale, has succeeded beyond the expectations of the parties interested; when first tried it was laughed at by some, and considered a Utopian scheme by many; whether its further extension will be deserving of support, is a matter for consideration. A gentleman of Epworth dibbled, the first week in November, 1843, two quarts and half a pint of golden-drop Wheat on 1 rood, 5 perches of land, the holes being 9 inches apart each way, two grains being put in a hole; and 5 quarts 2 pints and a half on 1 rood, 35 perches of land; half of the latter being in rows 12 inches apart, and 4½ inches in the row, two grains in a hole; the other half of the 1 rood, 35 perches the same distances, but three grains in a hole. The land is a light, black sandy soil, about 4½ inches deep; the subsoil a very light sand, and had been the previous year cropped with Potatoes, manured with very indifferent straw-yard manure, and had likewise been alternately cropped with Wheat and Potatoes for some years previously. The land dibbled suffered from the depredations of the birds, which got part of the seed. The following management was pursued after the seed was put into the ground:—Three sacks of soot were sown upon the land in December, yet the Wheat looked very thin and bad during the whole of the winter. About the middle of May 1 cwt. of Ichaboe guano, mixed with 2 cwt. of gypsum, was sown upon the Wheat, which, in consequence of the dryness of the season, did not appear to afford much benefit. It was twice hoed during the spring, and in May began to tiller and assume a luxuriant appearance, and maintained a dark healthy colour throughout; the straw was remarkably strong and of good length; the ears very large, many of them containing upwards of 70 grains, but averaged about 60 grains; there were 3 rows of corn, and some 4 in the ear; the stems varied from 8 to 21 from each root. The corn is a remarkably bold and fine sample, and weighed 14 stones per load of three bushels; the weight of the straw was not ascertained. The produce from the 1 rood, 5 perches of land, was over 12 bushels; and from the 1 rood 35 perches, 21 bushels, making 4 quarters 1 bushel of corn from less than 1 peck of seed on 3 roods of land. The growing crop suffered more from the drought, in consequence of being so thin upon the ground, than the thicker sown crops. The same gentleman sowed 1 rood of Wheat broadcast, 4 pecks per acre; 1 rood, 8 pecks per acre; and dibbled 1 rood, 3 pecks per acre. Having disposed of the land with the growing crops (which got mixed), the produce could not be known; but that sown with 3 pecks per acre had a decided superiority over the broadcast; if the land had been of a stronger nature, in better condition, and the weather moister, there is no doubt the crop would have been more abundant. The gentleman purposes repeating the experiment, being convinced of the practicability and advantages of the dibbling and thin-sowing system. —*T. B. Pearson, Epworth.*——*S. L. B.* adds—I am anxious that the system of dibbling Wheat should be fairly tried. Be so good as to say at what depth the seed should be sown; whether more than a single grain should be deposited in each hole; and at what distance from each other the holes should be made. The rows should, I understand, be six inches apart. I may here mention that the experiment of sowing some Wheat last January, much thinner than usual, has answered very well: the thin-sown has yielded considerably more. In the spring I had some difficulty in dissuading my steward from ploughing it down as a failure. A small quantity of Oats was dressed in the early stage of its growth with nitrate of soda; the effect is very striking, but I merely mention it to draw your notice to the subject; for though the increased produce of the dressed portion was obvious to every one who saw the field, I am afraid the steward has not kept that parcel by itself, which will prevent me from sending you an accurate return. I will send you soon the result of Campbell's steep applied to Oats. [Thank you: we should be glad to hear soon from others of our readers who may have steeped their grain, on this subject. Dibble Wheat in holes 1½ inches deep, and 6 inches apart every way; 2 seeds in each hole.]

Tanks.—If your correspondent "Joe" can heat the water in his tank, he will stop the leaking by introducing a peck of oatmeal into the tank, when the water is quite hot. I have recently tried the experiment with complete success. The oatmeal renders the water mucilaginous, and in its passage through the cracks it deposits a portion of the glutinous matter held in solution, and by degrees fills up the cracks. In the mountains of Scotland, flaws in the stills used for the manufacture of illicit mountain-dew are effectually closed by means of wetted oatmeal. I am assured that in the same manner defective iron boilers may be made perfectly water-tight. "Joe" has committed a mistake in not using pure cement. If all other measures fail, he may still accomplish his object by lining the bottom with roofing tiles placed close together and covering them with a coat half an inch thick of cement, unmixed with any other material, and applied by a workman who knows how to use it.——*R. G. L.*——Another correspondent says that he has three tanks, and all of them hold perfectly well; the liquid in them being secured by puddle dams of good clay 18 inches wide—the tanks being faced with brick. They are sunk in very open gravel.

Carbonate of Iron.—Is not this salt highly conducive to vegetation? It may frequently be seen in the bottoms of open drains (?) of an orange colour. I suppose it to be produced by a previously existing state of iron in solution, as a protoxide or as a sulphate of iron, both equally pernicious to plants. When exposed to the atmosphere, the iron probably unites with the carbonic acid of the air, and thus it becomes carbonate of iron. It will then be seen that Grasses thrive in it with much luxuriance, and if the contents of the drain be thrown out to its sides, better Grasses soon appear there. The subject deserves inquiry. There is not much encourage-

ment from the mere appearance of the yellow pulpy matter in question; it is commonly believed to be injurious, and so it is, as stopping the proper drainage of land. Ferruginous soils, however, are often very fertile. Arable land containing too much oxide of iron in solution, is improved greatly and immediately by the addition of calcareous substances. The benefit arising from composts of peat and lime may be greater or less in proportion as iron abounds or otherwise in the peat.—*T. P.*

Ononis arvensis.—Your correspondent "H. C.," (p. 660), should ponder well the following trite anecdote:—"An old farmer, on his death-bed, told his sons, who were not very industrious lads, that he had deeply buried his money in a particular field, which was the most barren land on his farm. In consequence of this information, soon after the old man's death the sons began to dig (and they dug deeply too) all over the field, and this they did again and again, for it was long before they quite despaired of finding the money. At length, however, they gave over the search, and sowed the land with Corn; when, from the thorough, deep digging and clearing which it had received, the crop which they reaped was indeed a treasure." Now, if "H. C." will imagine that he has buried a bag of dollars just below the roots he complains of, and will take the pains to look for them with the same assiduity which was exhibited by the aforesaid youngsters in their case, no doubt he will be rewarded as they were. If your correspondent were to cut off the plant close to the ground, just before it begins to blossom, scoop out a hole, and fill it with salt or hot lime, it would probably kill the root.—*Agricola.*

Quack Manures.—Some years since, Dr. Paris analysed and published his analysis of a number of quack medicines, then popular. Could not something of the kind be done with regard to quack manures? The most ignorant of your readers must know by this time that a variety of saline solutions exercise a powerful effect on vegetation in different ways, and that various of them will exist in solution together, without, at any rate, detrimental reaction. What a facility this affords to the manure doctor! Perhaps you will say that the increasing knowledge of Agricultural Chemistry will be the silent and certain remedy; but does not the enormous sale of patent medicines in this enlightened age prove that the mind of man is as fond of quackery as it is of novelty? Surely the old practical farmer's affection for and firm confidence in his muck-midden is now his safeguard and not his prejudice. Would that some sure analyst and uncompromising man would imitate Dr. Paris!—*Micklewell.*

Societies.

SOUTH DERBYSHIRE AGRICULTURAL SOCIETY.

At the Annual Meeting of this Society, held at Ashbourn on Saturday week, Mr. Colville, who occupied the chair, said that many of his brother cheese-makers were alarmed at the great importation of American cheese, and on this subject complaints were loud and frequent, many of the farmers anticipating ruin. It was by way of reply to these communications, and with the view also of relieving the minds of farmers in the cheese districts, that he was desirous of communicating some facts of which he had obtained possession. In order to obtain correct information on the subject, he had searched, with great care and labour, through the parliamentary returns for the last 12 years. The returns spread over many volumes; but he had reduced the main facts upon a sheet of paper, so that they might see at once how the case really stood. What he intended to show was this, that although the importation of American cheese was greatly increased, it had driven the Dutch cheese out of the market, and the aggregate importation is less now than it was several years ago. Though the American cheese had come in in shoals, the Dutch cheese, instead of being brought here as formerly, was taken elsewhere (to France he was told). He would now show them how the case stood:—

Year.	Imported from America.	From Holland or Belgium.		From other countries of Europe.	Aggregate of Importation.
	Cwt.	Cwt.	Cwt.	Cwt.	Cwt.
1831	0	133,397	..	1049	134,450
1832	50	126,112	..	1282	128,440
1833	None	131,286	..	1712	134,073
1834	1	145,004	..	1364	146,504
1835	0	139,694	..	2162	140,852
1836	1	210,026	..	1148	211,160
1837	1	235,679	..	1726	237,732
1838	2	235,691	..	2179	237,877
1839	None	209,847	..	1589	210,436
1840	41	224,887	..	1694	226,482
1841	15,154	..	260,998	..	276,149
1842	14,098	..	165,614	..	179,712
1843	48,313	..	150,000	..	198,313

By subtracting they would find that the importation of cheese during the last 10 years had actually decreased by nearly 32,000 cwts., while the population of the United Kingdom had increased by 2,300,000 mouths.

FARMERS' CLUBS.

Castle Douglas.—The following is an abridged report of Professor Johnston's second lecture here, taken from the *Dumfries Courier*:—The different substances of which plants are composed must exist in the soil on which they grow; according to the nature of the plant to be reared, so ought the land to be manured. Thus, while Wheat grain contained only two per cent. of ashes, hay contained 10 per cent. Hence the Wheat required a much larger amount of combustible ailment than hay. It was true that the whole of the combustible matter was not obtained directly from the soil, as a large portion of it was derived from the air; but from five to ten per cent. of the straw of Wheat was obtained from the soil, hence the provision made in some leases that no straw should be carried off the land. Different kinds of hay carry off different quantities of inorganic matter from the soil, and consequently have different effects upon the land. The following table shows the quantity of inorganic matter in 100 lbs. of hay:—

	In Rye Grass Hay.	Red Clover.	White Clover.	Lucerne.
Potash	6.8	19.9	31.0	19.4
Soda	3.9	5.3	5.8	6.2
Lime	7.3	27.8	23.5	44.3
Magnesia	0.9	3.3	3.0	2.5
Alumina	0.3	0.2	1.0	0.3
Oxide of Iron	0.0	0.0	0.6	0.3
Oxide of Manganese	0 0	0.0	0.0	0.0
Silica	27.7	3.6	14.7	3.3
Sulphuric acid	3.5	4.5	3.5	4.0
Phosphoric acid	0.3	6.6	5.0	13.1
Carbonic acid	0.1	3.0	2.1	3.2

The soil must contain all of the above, otherwise it cannot build up the plant which contains them; and just in proportion to the supply of the necessary ingredients, in their proper proportions, will be the luxuriance or stuntedness of the crop. Every plant that grows requires, in accordance with the nature and composition of soil, the proportion of the ingredients in its ashes. If no alteration of crops is made, Nature will become exhausted in some of her resources, and the plant, for want of nourishment, must die. We have facts to prove that Nature will not for ever grow the same plant on the same soil. The Black Forest consisted first of Oak, then of Pine, and now it is again covered with broad-leaved trees; and as with trees so with crops, and as on a large so on a small scale. Different modes of husbandry have been adopted. Instead of Oats being grown 15 or 20 years on the same soil, the rotation of three white crops and six years' Grass was adopted; this also has become antiquated, and now the preferable alternation of white and green crop is adopted. Alternating crops, and adding such manures as have been carried off by preceding crops, is the only profitable mode of cultivation, while Nature will also assist by the going on of certain circumstances, such as the decomposition of minerals, &c. &c. A soil containing just sufficient lime for a luxuriant crop of Rye-grass would be far deficient for either Clover or Lucerne. The soil must contain in abundance what your crop specially requires, and consequently the necessity of selecting the manure to suit the crop wanted; and skilful farmers will put this principle into practice, and also select crops suitable for the purposes to which they are to be applied; thus, if you wish to feed for milk you must select a plant containing an abundant supply of phosphoric acid; and this plant will not grow on land which has been exhausted of this acid, though it contained all other necessary ingredients in abundance. The ground becomes exhausted in many ways. By cropping too long with either one kind or different kinds of grain, and carrying off both grain and straw, it becomes exhausted very speedily. It becomes exhausted of some of its soluble matter by the action of rains, just in proportion to the wetness of the soil. By the application of proper manures the waste may be replaced. Feeding will replace a portion of the waste of solid matter; but a great portion of the soluble is lost, both by being, to a small extent, irrecoverable, and because of the direct waste by carelessness or ignorance. These soluble or saline substances are principally contained in the urine of cattle, and just in proportion as it is lost so is the direct waste. The urine of one single cow is valued in Flanders at 2*l.* per annum. What, then, must be the loss on the whole of the cows in Great Britain? Guano is not a more valuable manure than the urine of cattle, and yet farmers carry off this from their yards by large ditches, as if it were only, what it has too long been considered, a nuisance; while they will give 10*l.* a ton for an article of no greater value. By building suitable tanks the whole of the farm-yard saline matter might be preserved, and 900 lbs. of good solid matter, equal to the best Peruvian guano, would be the annual produce of one cow. Tanks ought to be made capable of containing all the urine voided in four months; they should be divided in the middle, and one end, when filled, should be allowed to ferment. This fermentation would be completed in about six weeks, when it should be carried to the land and applied as we now apply guano and water. In the process of fermentation, the ammonia is apt to escape; but by mixing the urine with three times its bulk of water, this will be prevented to a very considerable extent, as shown in the following table:—

Saline matter and ammonia in the urine voided by a cow in 12 months.

Recent urine contains—solid matter	lbs. 960	Yields of ammonia	lbs. 296
Kept 6 weeks—Mixed with water	850	,, ,,	290
,, ,, Unmixed	850	,, ,,	90

We have frequently been astonished at the results of certain saline substances when scattered over unhealthy plants, by the first shower washed into the soil, and immediately consumed by the plant as its proper and necessary food; and, just in proportion to the ease with which it gets the substances upon which it is supported, and of which it is composed, will it vegetate. Suppose any of the substances of which a plant is supposed to be already in the ground in sufficient proportion, then any addition cannot do good. Suppose soda to be in sufficient quantity for hay, any addition would be unprofitable for a Rye-grass crop, while it would be of immense benefit to double the quantity for Clover or Lucerne. And again, some soils contain it in sufficient quantity for every variety of crop, consequently any addition would be unprofitable. Hence the reason of so many conflicting opinions respecting the utility of manures. A. B. has a field deficient in the due proportion of gypsum; and by applying it to his crop he finds the most beneficial effects. C. D. hears of these results and applies it to his fields, which have already an abundant quantity of it, but require something else; and the consequence is, it does no good, and he pronounces it worthless as a manure; and his next neighbour, E. F., who would have been benefited by its application, has been dissuaded from applying it. Milk contains so much bony earth that in 75 years a cow pastured on an acre of land will carry off a ton of bones; hence some lands used for dairy purposes in Cheshire had, in the course of years, deteriorated to such a degree that they were not worth more than from 5*s.* to 10*s.* per acre, just because the cows pastured on them had carried away all the bone out of the soil. Bone-dust was at length applied as a top-dressing, and the results were so astonishing that the land increased 700 per cent. in value, and the rector's tithes were increased five-fold. Any or all other manures, had they wanted bone, would have proved ineffectual. The bones added just what had gradually been taken off in the lapse of years, in consequence of the peculiar husbandry of the district.

St. Quivox.—Having fixed the 14th ult. to commence their annual inspection of the farms occupied by the different members, the Club assembled at the residence of their president, and proceeded to examine the home farm of Craigie, where the different experiments with various kinds of manures attracted attention, and afforded information. The great interest taken in the proceedings drew together an unusual number of enterprising farmers. The different farms visited in the course of the day were—Mr. Young's, Dalmilling; Mr. Smith's, Braehead; Mr. Reid's, East Sanquhar; Mr. Hendrie's, Highfield; Mr. Reid's, Clune; Mr. Tennant's, Shields; Mr. Bruce's, Shaw; Mr. G. Hendrie's, Orangefield; Mr. Thomas Reid's, Fairfield Mains; Mr. Gairdner's, Monkton Mill; and Mr. Paterson's, Aikenbrae. The very high state of excellence which these farms displayed in every department, in the rearing and management of stock, in the extent and cleanness of the green crops, the luxuriance of the grain crops, and the richness of the pastures, drew forth the admiration of every one; while the different modes of management and manuring were keenly inquired into, and as freely communicated, tending to diffuse a vast amount of scientific and useful knowledge. Although the party, on leaving home in the morning, might have individually thought their own practice perfect, they must have returned in the evening better farmers, or at least with the determination of endeavouring to become so. On the following day the Club met at Gadgirth, and having inspected Mr. Gairdner's farm of Brocklehill on their way thither, proceeded to inspect the home farm of Gadgirth, which, from the varied experiments with special and other manures, so distinctly arranged, occupied a considerable time. The improvements effected by Mr. Burnett to those who may have seen his lands a few years ago, ere he began his operations, must be striking indeed, showing how, under a judicious and well-regulated system, a comparatively sterile and shallow soil may be converted into a deep and fruitful loam. The Club then proceeded to Mr. Inglis's farm of Stair, where a field of splendid Beans upon very poor soil attracted general attention, proving to what an extent this crop may be benefited by a moderate dressing of guano. The next farm visited was that of Mr. Bell of Enterkine, who displayed excellent crops of Turnips, Beans, Potatoes, and Oats. After another day spent in examining several other farms, these proceedings terminated. It is right to state, that although each farm did not show the same perfection in every respect, there was much judgment and scientific skill displayed in all, according to the locality, diversity of soil, and mode of farming pursued. We insert the above short account, in order to give publicity to a system worthy the adoption of all Farmers' Clubs; a system of annual visitation of the farms of members, which cannot fail to result in rapid agricultural improvement.

East Cornwall.—At the late meeting of this Society, the president, Goldsworthy Gurney, Esq., opened the discussion by calling attention to the management of Wheat stubbles. He was of opinion that they might be more profitably turned to account than by sowing Turnips, Rape, or lying fallow; he had transplanted Swede Turnips in several of his stubbles experimentally. It was of importance to know how late in the season the planting might be deferred with success, as the harvest this year was unusually early. He had manured some of the transplanted Turnips with guano, some with nitrate of soda, some with bone-dust, some with wood-ashes, and some with farm-yard manure. Those which he had transplanted in his stubbles were looking better than those transplanted in some parts of his fields where Turnips had failed. After some conversation on this subject, a discussion took place on the pickling of Wheat for seed. Mr. Pethick said he had used blue-stone (sulphate of copper) mixed with lime, successfully, for this purpose, about an ounce of blue-stone to the bushel. Mr. Thompson had used arsenic, but it was not effectual; he thought pickling very useful, and approved of the sulphate of copper. Mr. Badcock, St. Stephen's, observed that old Wheat-seed was not subject to smut, but that a greater quantity was necessary; the germinating power of old seed was well known not to be equal to that of new. The chairman remarked that the superior germinating power of new seed was a fact of some importance, particularly in connexion with Swede Turnip cul-

ture. The same year's seed was found so much better in practice that it would be well to get it raised in the south of France, or in some early climate, in time for Turnip sowing in this part of the country; he thought it possible that at Penzance, a place remarkable for its early crops, by a little management, Swede seed might be raised in time—a question worthy the notice of our western neighbours.

Mr. Kingdon begged Mr. Archer to favour the club with some further particulars, referred to last meeting, in connection with his mode of more economically keeping farm-horses. Mr. Archer said his stables were filled with ground-racks, but he did not generally use them; he had his hay and straw cut into chaff, in a loft above; the chaff was then mixed with the usual allowance of corn and let down through a tube to the manger below. The mouth of the tube and the manger were arranged on the principle of the bird-cage fountain, so that the horse could not breathe on, or otherwise injure his food, no more being drawn out than was eaten; by this means he had found 14 lbs. of chaff and two gallons of corn per day sufficient. Mr. Rodd then detailed the result of experiments made at Trebartha, on the field he had placed at the disposal of the committee. He had brought with him specimens of Turnips grown with the different manures recommended. Those from the ground manured with guano alone were far superior to any of the rest; those with bones, next in size; those with guano and sulphuric acid, and those with bone-dust and sulphuric acid, had both been comparative failures, as might be seen by the specimens he had brought with him. He would now detail the result of experiments on a subject introduced by their president, and which he perceived by the public prints had received his name, "Gurneism." He had brought with him specimens of the effects produced by its action, from different kinds of covering, all of which were labelled. The Grass under its influence would be observed to be a foot long, whilst that on the piece of turf, cut from an adjoining portion of the field, uncovered, would be seen to be but two inches in length. The greatest effect, however, had been produced by a basket-work netting. He had not been able to obtain any statistical data of the increase produced by straw, as the piece of ground hurdled off for this purpose had been broken into by his cattle, and the Grass had been eaten; the increase, however, had been great. Mr. Gurney observed that since their last meeting he had made several experiments; some showed the operation of light and shade. He had covered a piece of ground by day, removing the covering every night; vegetation under it was soon much increased, and of a similar appearance to that where the covering was constantly down. The increase was at the rate of 4000 lbs. per acre, in three weeks. On another piece of ground, covered by night, and uncovered by day, vegetation was evidently impaired, and looked unhealthy; there was no increase of Grass whatever. The fibrous covering in both these cases was long oaten straw, laid on at the rate of 20 lbs. to the land-yard.

Westfirle.—On Monday last the meeting of this Club took place. The subject for the evening discussion was, How far, or to what extent, can poor pasture or meadow lands be converted into arable, without raising the price of meat to the consumer?—A member said that he ploughed up four acres of turf which would not keep a sheep. He ploughed with four bullocks, let it lay till spring, raked up and burned the Grass, then ploughed again, and sowed red Globe Turnips, and the produce would keep 200 ewes for two months.—Another member said he thought when land was laid down, it ought to remain so six or seven years, as the accumulation of vegetable matter would be of advantage to the following crops. In Norfolk, where labour was cheap, it was laid down for four or five years.—A member stated that in some parts they laid the land down for two or three years, and then ploughed it again. This was the system on the Cotswold, which is a sheep-country. He was of opinion that it was of considerable advantage, and in breaking up he should not take the best or the poorest, as he doubted whether the latter would pay, as the produce would not perhaps be good enough to fatten cattle; in his opinion the old pasture land of England contained the raw material of more grain than the inhabitants could consume. Perhaps one reason why landlords objected to the breaking up of land was, that the tenant found when he entered a farm that the land contained a given quantity of vegetable matter, which was the landlord's property, and it was the tenant's duty to leave the land in the same condition; but if broken up, the landlords feared that the soil would be exhausted and impoverished; but he thought that when land was broken up a higher rent might fairly be expected by the landlord, as the farmer's profits would be considerably increased; he was also of opinion that by laying down other land the produce would likewise be greater; he had broken up land which was not worth above 7*s.* per acre, and it still retained the good quality which pasture land always bears to following crops—it worked better, and yielded better corn than the old arable; he broke up 30 acres and laid down 30 acres, and he found that that which he broke up yielded three times as much as that which he had laid down, but the produce would be larger for a considerable time. There was no question but that the laying down of arable land would do good, as by that means we conveyed to the soil a renewed supply of vegetable matter of which it had been deprived. He was in favour of the alternate system, as he believed the produce would be much greater on both arable and pasture land. The following resolution was adopted:—"It is the opinion of this meeting that many lands at present under pasture, might be broken up with much advantage, inasmuch as their value would be increased to the farmer, and the public would be benefited by the increase of stock and corn. At the same time, this meeting is further of opinion that, as a general practice, the alternate system would be preferable to any method of breaking up without restriction."

Barnet.—A meeting of landowners and farmers residing in this neighbourhood was held on Wednesday last, for the purpose of taking into consideration the injurious character of the existing system of hay selling, and to discuss the plan proposed to be substituted in lieu thereof, through the instrumentality of an Association, projected by some influential hay farmers in this locality. Several startling facts were stated to the meeting, proving the necessity of some exertion being made to lighten the burthen laid upon the hay farmer. From the year 1840 to 1843, the price of hay had been gradually falling, the average price of those years having exhibited a decrease of from 20*s.* to 30*s.* per load; while, on the other hand, the general crops of the last three years did not produce an average quantity. The scarcity of the present year's crop must, of course, cause higher prices, but that was an exception to the general prospect. There was a necessity, then, to see whether any relief could be obtained in the way of diminution in the charges or expenses incurred in the sale of hay. When any complaint on this subject was addressed to salesmen, it was invariably met by the cry of "Oh! look for a reduction of rent;" but, on the contrary, let the farmers see what the salesmen took from their pockets! The salesmen's charges amounted to no less than one-third of the rent of meadow land, or ten per cent. upon an average of the whole crop. This view of the case showed that it not only concerned the tenants, but the landlords also. The extent of the burthen imposed on the hay farmer under the present system, was truly surprising. A year or two ago an attempt was made to reduce the amount of the charges, but this was resisted by the salesmen, and the same per centage which was paid when hay sold from 5*l.* to 10*l.* per load, was still continued when the price of the article had fallen to 70*s.* per load. Believing that an absolute necessity existed that every endeavour should be made to reduce the charges which press so injuriously upon the farmer, several influential persons had attended meetings lately held to devise a remedy which was proposed to be effected through an Association of hay farmers, who would appoint their own salesman, taking upon themselves the responsibility of all sales on credit, abolishing the mischievous practice of throwing the risk of bad debts upon the agent, and providing a fund for prompt payment to those members who might be desirous of immediately receiving the proceeds of the hay sent by them for sale. A general outline of the rules proposed to carry out the intended new system of hay selling was then given, from which it appeared that a considerable reduction of the present charges would be at once effected; while in the event of the Association receiving the extended support of those for whose benefit it was especially designed, the charges would ultimately be reduced to a mere nominal amount. The object was a legitimate one, in which both landlord and tenant were equally concerned; and it was urged strongly upon the attention of the farmers and gentlemen of the neighbourhood.

Reviews.

Practical Instructions for using Guano as a Manure; illustrated by Practical Results. James Clark, 24 and 25, Billiter-street, London.

With the exception of eight or ten pages of original correspondence at the end of it, the contents of this pamphlet are compiled from works already before the public; and amongst these the columns of this Paper have been the fruitful though unacknowledged source of much useful matter. The directions given by Mr. Clark as to the use of guano are sufficiently trustworthy, and the evidence which he has gathered together of its value as a fertiliser is perfectly conclusive. We extract the following as one of his most interesting proofs of this. It is extracted from a letter by Mr. Grieve, of Archerfield, near Haddington:—"I have given you, in the following table, the result of a trial made by me last year, with four different kinds of manure, in growing Swedish Turnips: the manure was applied in the drills, without any moisture, and the Turnips sown on the 20th May, 1843. Where the guano was used they brairded more rapidly, were sooner ready for the hoe, and kept ahead of the others to the 27th November, when they were lifted and carefully weighed. The soil of the field on which they were grown is a dry, friable loam, and had been from time immemorial in Grass, until 1838.

Kinds and quantities of manures used per Scotch acre.	Price of manure per acre.	Weight of Turnips without roots or tops.	Weight of roots and tops.	Weight of rotten Turnips	Weight of total produce per acre.

Rape-dust, 12 cwts	3 0	3 19 1 20	5 0 0 0	2 5 6 20	17 2 1 0

On the same field where the Turnips grew, we sowed Wheat on the 17th February, 1844, without manure of any kind: no difference was observed in the Wheat till it came out in the ear. Where the dung was used, it appeared a little taller and stronger in the straw than that with guano; but the guano is decidedly better than either rape-dust or bones."

Miscellaneous.

On the Comparative Advantages of Employing Horses and Oxen in Farm-work.—This is a subject which has excited some controversy among agriculturists. Lord Kames wrote elaborately on it, and was at great pains in showing the superior advantages of employing oxen. His observations and calculations are not suited, in many respects, to the advanced state of husbandry in our day, however valuable they may have been three-quarters of a century ago. The writer of the following essay is situated in a district of Scotland where oxen are not much used in farm-work; but he has for several years past been in the practice of employing them himself; and in the hope that his observations may not be unacceptable to his southern brethren, he has presumed to send them across the Border. Previously to the discovery of shoeing in the ninth century, horses' feet having no protection against the stones and hard ground, and their hoofs not being so durable as those of oxen, the latter almost superseded them in field labour. Even up to the middle of last century, when there were few made roads, and when, consequently, all thoroughfares were nearly impassable for wheel carriages, agricultural produce was carried on the backs of the animals, oxen as well as horses. It may not be altogether out of place or uninteresting here to allude to the plough-team of former days. The manner of yoking oxen in early times seems to have been to fasten the draught gear to the horns. This barbarous practice extended even to a modern date. Lord Kames says—"People differ in the manner of yoking oxen; in some places they are yoked to the tip of the horn, and in some by the root; these modes are visibly inconvenient. When an ox draws by the shoulder like a horse, his head is free, and his motion natural; when yoked by the horns, he lowers his head to the line of the draught, his posture is constrained, and his step short; his neck indeed is strong, but his shoulder is a better fulcrum for the draught." This is very cool reasoning certainly. It was well for the poor brutes that the policy and interest of the master chanced to be accordant with humanity. Until about the end of last century, the ordinary collars were not used; a sort of stuffed bow was fastened round the neck, and the single tree lay on the shoulder, to which were fastened the chains for drawing by. The array of numbers and apparent strength employed in a plough-team would astonish our modern agriculturists. From the earliest times, I presume, up to about the year 1760, as many as from 12 to 20 oxen, and 6 or 8 horses would have been engaged in drawing one plough; this can be partly accounted for otherwise than by the rude and awkward manner of yoking. Before 1770 very little breadth indeed of artificial Grasses was sown. The ground was cropped for a succession of years, until the natural Grasses (what we now term weeds) got thickly and firmly rooted, the growth of which afforded food during the day in summer for the animals, and at mid-day the ploughmen pulled thistles from among the corn for night provender. In winter the horses were allowed about a feed of Oats daily, with Oat-straw; the oxen got the latter only. While thus poorly fed, the animals had not strength in the draught; hence the numbers requisite. The farm which I occupy has been tenanted by my ancestors for many generations. At the time of the Revolution, my great-grandfather, and his son for many years after that, employed 12 working horses and 28 working oxen, one half of each set being yoked to one plough; I now work the same land to better purpose, I presume, with 6 horses and 2 oxen. In further discussing this subject, I shall endeavour to treat it in the order pointed out in the conditions:—1. *The Age and Breed of the Horses and Oxen, and the time at which they are first put to Work.*—Horses in this country are put to work at three years old; they are often from the commencement worked steadily, although it is considered prejudicial to their future development. I am not aware of the breed of the farm-horse in the middle and northern districts of Scotland being recognised by any particular name. The most perfect figure of a draught-horse is that of the Clydesdale breed; he is distinguished by a short compact body and strong broad bone, these properties being characteristic of strength and durability. Oxen are put to work somewhat older than horses, and they are not at the outset so able for steady work; they cannot be depended on before they are four years old. Our work oxen are bred principally in the shires of Angus and Aberdeen. The peculiarities in their figure are, a small head, deep chest, round body, and short legs. The largest sizes, although frequently selected for work, are, I conceive, not the most proper. They have naturally small bones in comparison with the size of the body; hence the strength of the limbs and the weight of the carcass do not always correspond in reckoning them as "beasts of burthen." The weight of my oxen averages about 800 lbs. without the offal, when fed. When much heavier, I find they want activity and endurance, and their feet, from the additional weight, are more apt to give way. 2. *The Condition of Horses and Oxen, the Work performed by each, and its relative Value; Nature of the Soil where worked.*—In all well and economically managed farming establishments, due regard is had to the keeping the horses in good condition. Efficient work can never be performed by ill-fed, ill-groomed animals. The ordinary allowance of food to each horse daily is 16 lbs. of Oats, and as much Oat-straw as he chooses to eat. My oxen get as many Turnips as they can eat. They are fed four times a day, at 5 A.M., 11 A.M., 6 P.M., and half-past 8 P.M., and at each time they eat betwixt them 125 lbs., being in all 500 lbs. daily. I often slice the Turnips for them, especially at mid-day,

when they have little time to eat. They never drink any water even in the hottest days of summer. Both horses and oxen graze in summer; I have not ascertained which of them require the most Grass. In regard to the work performed relatively by horses and oxen, I should say that, except in frost, when the land cannot be ploughed, the amount and value of the work performed by each are equal. Many people who work oxen keep 4, and work each pair only one half of the day. This is a most expensive system; and, were a good selection of the oxen to be made, is quite unnecessary. I never keep more than 2 at one time, and they work 10 hours a-day as steadily all the year over, except in frost, as the horses, and keep in perfectly good condition. We often see oxen going very slow and sluggardly at work; when well trained, and of a proper breed and size, they will step out as well and as fast as horses: mine do so. At a late ploughing-match in the district, where upwards of 70 ploughs started, my ox-team was second off the field. The average period when frost prevents ploughing may be stated at six weeks. During this time, except in the threshing-mill, oxen are unemployed. The horses are then engaged in carting dung, earth, &c. By calculating the work of the pair of horses, without the man's wages, as worth 6*s.* a day, and allowing 1*l.* 16*s.* as the value of the threshing-mill work performed by the oxen during frost, we have the sum of 9*l.* standing against the latter. It will not do to listen to statements partly speculative and hypothetical, about the capabilities of oxen for drawing wheel-carriages; it is enough for our purpose at present to know that they are not so employed; they are, in the time of frost at all events, unsuited for such a purpose. The soil best fitted for oxen to tread on is that which is dry and most free from stones. My farm is composed of both clay and black soil, some of the former of which is rather wet, but there are very few stones anywhere. My oxen, although un shod, and working as I have said steadily, never get the least lame, or suffer in the slightest in their feet. On another farm, however, which I occupy, where the soil is more of a clayey nature, and somewhat wet and stony, the hoofs of the oxen were, and became tender, and rendered them unfit for steady work. Attempts have been made to shoe them in such circumstances, but the experiment seldom proved satisfactory. The conclusion to which I have come is, that oxen cannot by any management or precaution be profitably employed on wet or stony soil. 3. *The Cost of Maintenance and Farriery of each Pair of Horses and Oxen, including the separate Charge of Management.*—A horse getting 16 lbs. of Oats daily will eat in seven months (the period he requires grain) about 10½ quarters, which in value amounts to nine guineas. A horse wears 5 or 6 sets of shoes annually, which cost 18*s.*; other 5*s.* will be allowance enough for medicine. In regard to the cost of maintaining working oxen on green food, such as Turnips, I have to remark, that the price of that article varies according to the locality where it is grown. I shall reckon the price or value of the ton of Turnips at 10*s.*, being the average in an inland district. I have repeatedly ascertained, both now and formerly, the exact quantity of Turnips which oxen eat, and find that two daily consume about 500 lbs., being at the rate of a ton in four and a half days, or 47 tons in seven months (the time they require Turnips), which in value amounts to 23*l.* 10*s.* I make no calculation on the cost of straw. I believe the quantity eaten by a horse and ox to be about equal. The charge of management of horses and oxen is the same. One man has the charge of a pair, and all must be groomed and otherwise attended to alike. 4. *The Cost or presumed Value of each Pair of Horses and Oxen with their Gear, when put to work, and their Value at the end of the Comparison.*—A pair of farm-horses, four years old, suitable for all kinds of work, can be bought for 56*l.* Their gear or harness, including the cost of keeping it in repair, amounts to 25*s.* yearly. Should no accident occur a horse will last twelve years, at the end of which time he is worth about 6*l.* Including the difference between the original purchase and ultimate selling price, together with interest, the sum of 3*l.* 10*s.* is thus lost annually on each horse. There should be added to this at least 30*s.* to cover accidents and deaths. A pair of oxen, four years old, costs 26*l.* The last pair which I bought cost 24*l.* They have worked regularly for four years, and I am now feeding them for slaughter. I expect to get about 30*l.* for them. They work one day a week at the threshing-mill, which does not seem to retard their feeding. I would therefore calculate that no actual loss will be sustained on oxen from the time of their being bought and sold. The cost of gear, including keeping in repair, costs 10*s.* annually. The account of the different items stands thus:—

Expenditure, &c., on a working horse yearly.

	£	s.	d.
To 10½ quarters of Oats, at 18*s.*	9	9	0
To deterioration in value, interest on outlay, losses by accidents and death	5	0	0
To shoeing and medical attendance	1	0	0
To furnishing and repairing gear	1	5	0
	£16	19	0

Expenditure, &c., on a working ox yearly.

	£	s.	d.
To 23½ tons of Turnips at 10*s.* per ton	11	15	0
To furnishing and repairing gear	0	10	0
To loss on his work during frost	4	10	0
To interest on purchase price	0	15	0
	£17	10	0

In the above table, I have calculated the Oats given to the horses at the market price; but the cleanings and inferior grain, which cannot be otherwise disposed of, constitute a considerable portion of their food, and thus the cost on this item can be reduced; otherwise the figures above so nearly correspond, that it rests with the partiality of parties whether they shall employ horses or oxen, or partly both. For my own part, after duly considering the matter, and after the experience of a number of years, I should give the preference to employing horses exclusively. They are ready at all times for all kinds of work; in wet or frosty weather they can be employed in carting, and in leading the crop in harvest they are invaluable and indispensable, while at all these times the oxen are "eating the bread of idleness."—*Prize Essay in the English Agricultural Society's Journal, by J. Cowie, Laurencekirk, N. B.*

Notices to Correspondents.

Books.—*J. K.*—Reid's "Chemistry of Nature," Glasgow.

Chaff-cutters.—*Toby* and *A Subscriber.*—The price of these implements, of the small size, for one man, may vary from 6*l.* to 10*l.* They will cut, perhaps, three different heights. We cannot select and name the firm from which you should buy. You must ascertain this elsewhere.

Failure in Seeds.—*J. Robinson.*—We are afraid it is too late now to sow Italian Rye-grass, which would probably have been your best remedy, could you have applied it in August. If your seeds are a failure, you had better plough up and sow winter Vetches.

Failure on the Cotswolds.—*G.*—You have mistaken the character of the soil on the Cotswold hills. It is a poor, thin, brashy, calcareous soil; certainly not overburdened with nitrogenous manures. No cheese is made there—that is all manufactured on the pasture lands in the vale. Turnips are sown broadcast; but the farmers rarely use artificial manures: they depend chiefly on what is made at home in their farm-yards. Your argument as to the cause of failure, you will thus see does not avail you. The Turnips have failed more likely from want than excess of manure.

Gorse.—*Melksham.*—See Nos. 5, 6, 9, and 10, of the *Agricultural Gazette.*

Indian Corn.—*An Inquirer.*—Your idea of the want of gluten in this grain, as compared with Wheat, we have always considered correct. We do not know on what authority Mr. Lyde states it to contain so much. Payen, as quoted by Professor Johnston, found nearly 5 per cent. of gluten in Maize; but his analysis, from its obvious inaccuracy in other matters, Mr. Johnston says is not to be depended upon.

Operation on the Snouts of Pigs.—*W. D. F.*—There are two tendons, which, with their parent muscles, elevate the snout, and endow it with the power of rooting up the earth. These tendons may be divided about 1¼ inch from the nose. A piece of each should be cut out, and the wound kept open a while by means of tow: a simple division of them would answer no end, as they would soon unite again; but by cutting out a portion, their power would be diminished.——*W. C. S.*—See No. 5 *Agricultural Gazette.* It is evidently a more cruel operation than that of ringing.

Sea-sand.—*J. White.*—Large quantities are used; you will find it expensive to apply per acre an equal quantity of lime in bone-dust; it will answer as well, but the expense will render it unadvisable. If you apply lime along with guano, you will expel much of the ammonia which the latter contains. Lime is useful on soils which do not contain it. Guano or some other source of phosphorus, ammonia, &c., is also necessary on such as well as on others; but the two must be applied at separate times; apply lime in autumn, and guano in spring. Salt would be useful on your soil, if you are far inland, and you may apply it with your bones and acid or otherwise, at the rate of 1½ or 2 cwt. per acre. The mode of its application does not signify, provided it be evenly spread in wet weather.

Sulphate of Iron.—*Original Subscriber.*—It will decompose carbonate of ammonia, as soon as it is formed in urine. We shall be better able next week to say what effect it would have on the feet of animals in a house.

Weeds.—*A. Langdon.*—We have to apologise for delay. Your Weed can be extirpated only by perseverance in pulling it, and destroying it in all possible ways. It is very rarely indeed that the farmer knows of any easy way to destroy weeds, or indeed of any other way than sheer industry and perseverance in pulling them up.

*** As usual many communications have been received too late.

Markets.

SMITHFIELD, Monday, Sept. 30.—Per stone of 8 lbs.

Best Scots, Herefords, &c.	3s 0 to 4s 0	Best Downs & Half-breds	3s 8 to 3s 10
Best Short Horns	3 8 3 10	Best Long-wools	3 6 3 8
Second quality Beasts	3 2 3 4	Ewes and second quality	3 0 3 6
Calves	3 4 4 0	Lambs	3 8 4 4
Pigs	3 4 4 0		

Beasts, 2956; Sheep and Lambs, 20,690; Calves, 117; Pigs, 370.

Our supply of Beasts to-day is unusually large, still the best qualities are not over-abundant, and maintain Friday's prices; trade for all other qualities is excessively bad—this being Michaelmas Market, very little is wanted; several middling Beasts remain unsold. There is also a considerable increase in the supply of and decrease in the demand for Sheep; trade is very heavy at a reduction of about 2d per 8 lbs. on the general trade, although in some few instances the best Downs make 4*s.* and Longwools 3*s.* 10*d.* There are fewer Lambs; they are a little more in demand, but make no more money. Veal-trade is heavy; middling Calves are very low. Pork is about the same.

Friday, Oct. 4.

The supply of Beasts is large, and demand very small: the best qualities barely maintain Monday's quotations, and it is difficult at all to dispose of the inferior; a large number must remain unsold. Although the number of Sheep is considerably less, there is more than sufficient for the demand, and the prices are a trifle lower than on Monday; the trade at the dead markets having been so excessively bad since Monday causes a very slack attendance of buyers here to-day. Veal-trade is also rather worse; the very best Calves barely make 4*s.*, and a great many inferior quality make no more than from 3*s.* to 3*s.* 6*d.* Pork-trade is steady at late quotations.

Beasts, 631; Sheep and Lambs, 6110; Calves, 248; Pigs, 280.

41, West Smithfield.

POTATOES.—Southwark Waterside, Sept. 30.

There have been three or four small lots of Jersey Whites sold at 5*l.* per ton, and if sales had been pressed, lower prices would have been the consequence; there has also been some small lots of Whites from Lincolnshire, and a few barges from Kent, yet the number of arrivals has been inconsiderable, and the demand inactive—but at present there has been nothing to draw the Trade to the Waterside.

HAY.—Per Load of 36 Trusses.

Smithfield, Oct. 3.

WOOL.—British, Friday, Oct. 4.

There has been but little doing during the past week. Combing Wools continue of dull sale, and we have heard of a slight reduction in prices. Few lots have been submitted to in some cases. The market for Short Wools has partially been good, but prices have not varied.

Oak Bark (per load of 40 cwt.), 10*l.* to 12*l.* 10*s.*

HOPS, Friday, Oct. 4.

The Market is very active, and prices have advanced 4*s* to 6*s* per cwt. since last week. The duty is still estimated at 13 ,000*l.*

Farrer, Ames & Farrer, Hop-Factors.

MARK-LANE, Monday, Sept. 30.

There was a fair supply of Wheat from Essex and Suffolk this morning; that from Kent was large; the condition of all is much better than it has been since harvest, and met a tolerably free sale at 1*s.* per qr. above the prices of this day se'nnight. Foreign was also in improved demand at a similar advance. Canadian and American Flour is rather more inquired after at our quotations.—Malting Barley is readily taken off at the prices of last week; secondary and grinding qualities are neglected.—The value of Beans and Peas remain unaltered from last week.—The Oat-trade is firm, and rather more money is obtained for retail quantities, but the dealers are holding off for larger arrivals.

Rimmington and Lay.

COVENT GARDEN, Oct. 5.—There has been little variation in the prices of most articles during the past week; the market has been well supplied, but trade continues dull. Pine-Apples are sufficient for the demand; among them there are many handsome fruit. Melons continue to be supplied in tolerable abundance; and Grapes are very plentiful. Peaches and Nectarines are becoming scarce; a few good samples, however, still remain, and they appear to be pretty good. The chief dessert Plums are Coe's Golden Drop, and the Imperatrice, which fetch about 1*s.* 6*d.* per punnet. Of Apples and Pears of good quality there is abundance offered at last weeks' prices; they consist exactly of the same kinds as are mentioned in our last weekly report. Hothouse Grapes are nearly the same as last week; Spanish varieties are a little cheaper. Very few Oranges are in the Market, and Filberts still continue scarce. Of Vegetables, generally speaking, there are plenty; Broccoli, of which a considerable quantity is in the Market, is becoming more plentiful. It is very good and cheap. Cauliflowers are scarce, as are also Cabbages. Brussels Sprouts are getting more plentiful, and Carrots and Turnips are supplied in considerable quantity. French Beans are scarce, and are in consequence getting dearer. A few samples of Peas may still be met with, which are tolerably good in quality. Onions are large and fine, as is also Celery. Lettuces and other Salading are sufficient for the demand. Cut Flowers chiefly consist of Ceanothus azureus, Gladiolus psittacinus, Pelargoniums, Phloxes, Heaths, Verbenas, Fuchsias, Amaryllises, Camellias, Carnations and Roses.

Fruits.

TO NOBLEMEN, GENTLEMEN, TRUSTEES OF LANDED PROPERTY, and OTHERS.

MESSRS. BROOKS and GREEN have an opportunity of introducing a Gentleman who has been accustomed for many years to superintend the Farming Department of an extensive Estate, and thoroughly understands the most approved principles of Agriculture, Breeding, and Management of Stock, and who now wishes to devote a great portion of his time for the same purpose in any of the Midland Counties. Satisfactory references will be given, both as regards capability and integrity, by addressing to Messrs. BROOKS and GREEN, Estate Agents, Surveyors, and Auctioneers, 52, Old Bond street.

STEPHENSON AND CO., 61, Gracechurch-street, London, and 17, New Park-street, Southwark, Inventors and Manufacturers of the Improved CONICAL and DOUBLE CYLINDRICAL BOILERS, respectfully solicit the attention of scientific Horticulturists to their much approved method of applying the Tank system to Pineries, Propagating Houses, &c. by which atmospheric heat as well as bottom-heat is secured to any required degree without the aid of pipes or flues. S. & C. have also to state that at the request of numerous friends they are now making their Boilers of Iron as well as Copper, by which the cost is reduced. These Boilers, which are now so well known, scarcely require description, but to those who have not seen them in operation, prospectuses will be forwarded as well as reference of the highest authority; or they may be seen at most of the Nobility's seats and principal Nurseries throughout the kingdom.

S. & Co. beg to inform the Trade that at their Manufactory in New Park-st., every article required for the construction of Horticultural buildings, as well as for heating them, may be obtained upon the most advantageous terms.

Conservatories, &c. of Iron or Wood, erected upon the most ornamental designs. Balconies, Palisading, Field, and Garden Fences, Wire Work, &c. &c.

HOT-WATER APPARATUS FOR HEATING HORTICULTURAL BUILDINGS, DWELLING-HOUSES, CHURCHES, and MANUFACTORIES, upon improved principles, and at very moderate charges, erected by DANIEL and EDWARD BAILEY, 272, HOLBORN.

D. and E. BAILEY having devoted much time to the consideration of this subject, and had much experience in the erection of apparatus for the above-mentioned purposes, have, by improvements suggested in their practice, rendered their mode of heating not only very efficient, but very simple, and have combined durability in the apparatus with economy in the charge. They have erected apparatus in England, Scotland, and Ireland, for many noblemen and gentlemen, and have had the honour to be employed by the Horticultural Society of London, in executing the works of their splendid Conservatory, lately erected at Chiswick.

D. and E. BAILEY also construct in metal all descriptions of Horticultural Buildings and Sashes, and invite noblemen, gentlemen, and the public to an inspection of their various drawings and models, at 272, Holborn, where they have the opportunity of exhibiting, amongst other metal works, an extremely complete and convenient kitchen apparatus, or range, adapted for the continued supply of hot water, and an arrangement of the oven more complete than has hitherto been brought before the public.

D. and E. BAILEY were the first to introduce metallic curvilinear houses to horticulturists, and can refer to the Conservatory attached to the Pantheon as one of their works, besides many others in this country and on the Continent.

D. and E. BAILEY have prepared a quantity of the Galvanic Plant Protectors, which are now ready for immediate delivery: they beg to introduce to public notice a new Trough Pipe, for Orchidaceous or other Houses where vapour is constantly, or at intervals required, and which may be seen at their Manufactory.

WHEAT-SOWING.

GUANO; Genuine Peruvian, Bolivian, and Ichaboe, on Sale; also Potter's Guano, Gypsum, Sulphuric Acid, Sulphates of Iron and Copper, and all other manures. Synopsis of prices, and mode of use, on application, &c.—Apply to MARK FOTHERGILL, 40, Upper Thames-street.

GUANO (GENUINE PERUVIAN & BOLIVIAN) ON SALE, BY THE ONLY LEGAL IMPORTERS, ANTONY GIBBS AND SONS, LONDON; WM. J. MYERS AND CO., LIVERPOOL; And by their Agents, COTESWORTH, POWELL, AND PRYOR, LONDON; GIBBS, BRIGHT, & CO., LIVERPOOL and BRISTOL. 47, Lime-street, Oct. 4, 1844.

GUANO for SALE, in Bags of 1 cwt. each, just landed, with a succession of cargoes to arrive.—Successive years' experience has unquestionably proved that Genuine Guano is the simplest, cheapest, and best Manure within the reach of the Agriculturist. The only reasonable anxiety which now remains is to procure the Guano unadulterated, and to obtain such practical directions for using the Manure as shall fully develop its productive powers. To secure to buyers these indispensable requisites, with each purchase will be given a warranted chemical analysis of quality, and also a copy of the recently-published Pamphlet, "Practical Instructions for using Guano as a Manure, illustrated by Practical Results."

Large parcels will be delivered direct from the ship or waterside premises; smaller quantities may be had at the warehouses, 24 and 25, Billiter-street, or delivered within any reasonable distance at a trifling additional cost. Apply to JAMES CLARK, 24, Billiter-street.

MANURES.—The Readers of the *Gardeners' Chronicle* must have noticed the complaints constantly made there of the Adulterations of Manures, and which are now carried on to a fearful extent.

The Advertiser, a Broker of the City of London, and in daily communication with several scientific Chemists, calls the attention of the Nobility, Agriculturists, and Farmers to his method of supplying Manures, by which a genuine article is secured. Each article is Analysed, and the Analysis forwarded to the purchaser, who can by this means obtain redress should the article differ from the Analysis.

Terms, Cash and one per cent. commission for buying and forwarding.

A register will be kept of the Analysis of every cargo of Guano imported into London that is brought in the market.

Price-current, London, Oct. 7, 1844:—

Bones	p. ton	£4 10s. to £5	Nit. of Potash	p. cwt.	£1 4s.6d
„ crushed	£5.10s.to	6 0 0	Oil of Vitriol, or Sulph.		
„ calcined	„	7 0 0	acid	p. lb.	0 0 1

„ Ichaboe	„	6 0 0	„ Glauber	„	7 0 0
Gypsum	„	2 0 0	Sulphate of Ammonia, per cwt., 10s. to		0 17 0
Nitrate of Soda	p. cwt.	0 14 0			

WM. NORRISCOTT, 18, Rood-lane, Fenchurch-street.

POTTER'S GUANO MANURE is the only Guano that can positively be depended upon, and has stood the test of three seasons. The imported article, it is well known, is seldom twice alike, even when genuine, and is subject to a most extensive system of adulteration. Orders addressed solely to the Works, 28, Upper Fore-street, Lambeth, will have instant attention. Testimonials will be sent per post, if required.

POTTER'S LIQUID GUANO may be had as usual, at most Ostlers and Seedsmen.

☞ Beware of being imposed upon by ineffectious imitations.

WHEAT-SOWING.

FREDERICK BRAIN begs to call the attention of the Agricultural world to his GUANO MANURE, prepared expressly for Wheat crops: it abounds in all the ingredients that are necessary for a good grain crop. He particularly solicits persons who found the Foreign Guano a failure last season to give his a trial, it being much more powerful, and free from adulteration, so justly complained of in the Foreign by Agriculturists, as well as by all the leading Agricultural Journals.

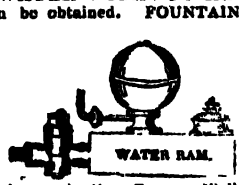
Testimonial to Brain's Guano Manure.—"5 A, Hawley Road, Kentish Town, London, Aug. 15, 1844.—This is to certify that we have subjected Brain's Guano to a most patient and rigorous analysis, and find it contains all the necessary constituents of a good manure, and is well calculated to give fertility to a soil which is either naturally barren, or has been exhausted by over-cropping, by supplying the land with those substances which are absolutely requisite to a healthy vegetation: (it is not adulterated, and can always be depended on, being of uniform composition.)—(Signed) JOHN MITCHELL and FREDERICK FIELD, Analytical Chemists, late of the Royal Polytechnic Institution, London."

Also, BRAIN'S highly-concentrated LIQUID GUANO, for Grass Lands, Gardens, Shrubberies, Hothouses, and Conservatories, price 1*s.* 9*d.* per quart bottle, with full directions for use, (enough for 80 gallons of Liquid Manure), to be had of most respectable Florists, Seedsmen, and Chemists in town and country.

Works, Thomas-st., Duke-st., Stamford-st., Blackfriars-road.

SEED WHEAT.

J. D. PIPER, of Colne Engaine, Essex, (Member of the Royal Agricultural Society), has been four years raising two new Stocks of Wheat, viz., Piper's "Thick-set," and "Colne Whitechaff Red." At the last Southampton Meeting two sheaves of these Wheats were exhibited outside (notice not having been given in time for their admission inside), where they produced much excitement, and 5*l.* per ear was offered for them. Last year, in the same field, side by side, the Piper's Thick-set grew eight bushels and a half, and the Colne Whitechaff Red five bushels and a half more per acre than the most prolific Wheat grown in the neighbourhood. Last autumn J. D. P. measured a quarter of an acre off his field, and dibbled the Thick-set in rows a foot apart, and one bushel per acre; and though the plant was partially destroyed by the slug in the winter, and a good sprinkling of self-sown Potatoes were left to grow, still the yield was 14 bushels and a half, being equal to 14 sacks and 2 bushels per acre. One person this year grew 15 sacks and 2 bushels, another 14 sacks, and another 13 sacks per acre. One parcel weighed 64½ lbs. per bushel. This is, perhaps, the stiffest-strawed Wheat in England, and is adapted for strong or hollow bottom ground, and is not likely to get laid. J. D. P. will send to London, or to any place within ten miles of Colne, carriage free, and he will be glad to receive a post-office order, or reference to some house in London for the money, with the order for the Wheat. When it is all sold, J. D. P. promises to inform the Public, by an advertisement in this Paper; but if he should get any post-office orders after it is all sold, he will return them. The price is regulated according to the yield. Thick-set, 15*s.* per bushel; Colne Whitechaff Red, 9*s.* per bushel. Samples of the above, both threshed and in the straw, may be seen at our Office. N.B.—J. D. P. advertised in the two principal papers in Essex, where the above Wheat was growing, in order that Agriculturists might see it and judge for themselves of the quality and quantity.



IMPORTANT TO AGRICULTURISTS, &c.

ANALYSES of SOILS, MANURES, and all AGRICULTURAL PRODUCTS, are conducted by Messrs. MITCHELL and FIELD (late Mr. Mitchell), Analytical Chemists, with the view of ascertaining whether the Soil, in which it is proposed to grow any particular crop, contains all that is necessary to produce a luxuriant vegetation; also to estimate the relative value and purity of Manures, and the comparative worth of Farm Produce in general. Gentlemen instructed in Agricultural Chemistry. The course will comprehend the Elements of Analysis.—No. 5 A, Hawley-road, Kentish Town.

70, STRAND, LONDON.

RAMS FOR RAISING WATER WITHOUT LABOUR, where a fall can be obtained. FOUNTAIN BASINS IN IRON, &c.

F. ROE having purchased all the Patterns of Basins, Jets, &c. formerly belonging to W. Rowley, Fountain Maker to the Royal Family, is enabled to offer the above article in iron, which will stand the Frost and last for ages. A Ram and Fountain Jets fixed on the premises for inspection. Every kind of Garden and other Pumps, Well Engines, Baths, &c. Houses, &c. Heated by Hot Water.

WATER RAM.

TO LANDOWNERS, AGRICULTURISTS, BUILDERS, &c.

McKIBBIN'S Improved ROOFING FELT is peculiarly applicable as a substitute for Slate, Zinc, Tiles, and other articles used for Roofing, from its ECONOMY, LIGHTNESS, and DURABILITY.

The disadvantages attending other materials used in roofing, preventing, to a great extent many useful houses and sheds being erected or rendered waterproof, it is submitted that the improved Roofing Felt will in a great measure—and in some instances altogether—obviate them, and prove most serviceable from its lightness, durability, and impermeability to water and damp, in covering Houses, Cattle-sheds, Workshops, Ropewalks, &c., and for the sides, as well as roofs, of light structures for plants, being likewise a non-conductor of heat; besides its economy in repairs, the timber where it is used may be so light as to save its whole expense; it requires no other coping, and may be applied by any person of common ingenuity; being flexible and portable also, it is free from breakage, the expense of carriage is inconsiderable in comparison with slates, tiles, &c., and it is not liable to contraction like zinc.

Sold in sheets 32 inches by 20, at 3*d.* each (being less than 9*s.* 6*d.* per square of 100 feet), with printed directions for applying them, same as adopted at the Government Dock-yards and various other public buildings.

Orders will meet with prompt attention if addressed to H. C. BOWDEN, 18, East India Chambers, Leadenhall-street, London, or to the following agents:—Liverpool, Messrs. Grueber & Co., 11, Mansety-lane; Plymouth, Thomas Stevens, Esq.; Birmingham, William R. Loyd, Esq.; Sunderland and Newcastle-on-Tyne, Messrs. John Ritson and Sons; Hull, William Ward, Esq.; Bristol, Messrs. Moor and Hawkins; Ramsgate and Deal, Messrs. Edward Hodges & Co.; Whitehaven, William Todd, Esq.; Glasgow, Malcolm Carmichael, Esq., St. Enoch-square; Cork, Messrs. Richard Wallis & Co.; Belfast, Messrs. Grueber & Co., Dunbar's Dock; who have also on sale McKIBBIN'S improved SHEATHING, BOILER, RAILWAY, and other FELT.

☞ The "IMPROVED ROOFING FELT" will be found much more durable than the Common Felt made in lengths, and not subject, like it or continuous sheets of other material, to be stripped by storm; it can also be more easily repaired, and from the simple mode of application recommended, the wet cannot percolate through nail-holes, being only fastened down at the overlaps.

J. R. AND A. RANSOME, Ipswich, have published a Descriptive Catalogue, with Cuts, of their AGRICULTURAL IMPLEMENTS and MACHINES, which may be had by post, the order being accompanied by six penny stamps.

PORTER'S GALVANIZED CORRUGATED AND PLAIN IRON ROOFING, and IRON HURDLE and FENCE WORKS, Grove, Southwark. The Patent Galvanized Iron Co.'s (Lord's) process, is now being used for the Roofing of the New Houses of Parliament; at Woolwich Dockyard, by the Trinity Board, &c. It is particularly suited for the Colonies, and is shipped by J. PORTER to the East and West Indies, Ceylon, &c.; also supplied by him to several English, and to the Jamaica Railway Companies. Movable Feeding Sheds and Pens, Patented and Fireproof Buildings of all kinds. A new description of Galvanized Iron Open Gutter covered with tile for the navigation of hot water, much cheaper than any other kind. The Trade supplied with Corrugated Plates, Galvanized or not, and with Iron Fences of all kinds.

BY HER MAJESTY'S ROYAL LETTERS PATENT.

PATENT ASPHALTE ROOFING.

THE above Material has been used and approved by the Nobility, Gentry, and Agriculturists generally, as a Roofing and Covering to sides of Farm Buildings; its advantages are—Lightness, Durability, and Economy. Being a non-conductor, it has been proved an efficient Protective Material to Plants, and is now in use at the Royal Horticultural Society's Gardens, Chiswick. It can be had of any length, 32 inches wide, at 1*d.* per foot, super. A discount to the trade. THOS. J. CROGGON, 8, Ingram-court, Fenchurch-st., London.

EXTIRPATION of all kinds of VERMIN.—Office, 69, King William-street, City, London.—MR. J. A. MEYER, practical chymist, patronised by Her Majesty the Queen, H.R.H. the Duchess of Kent, the Royal Agricultural Society of England, and the Corporation of the City of London, and by special appointments to the principal Courts of Europe, begs to inform the nobility, gentry, merchants, agriculturists, shipowners, and the public generally, that he continues to CLEANSE, by contract, from one to five years, every description of PROPERTY, of rats, mice, moles, weasels, moths, fleas, bugs, &c., and as a guarantee of the efficacy of his preparation, respectfully refers to the certificates of his great success at Buckingham Palace and Gardens, Windsor Castle, St. James's Palace, Frogmore Lodge, Carlton Club House, Mansion House, Newgate Prison, Tavistock Hotel, Brewers, Chester, and Galley Quays and warehouses in Lower Thames-street, the property of Joseph Barber, Esq., and many others of public and private establishments, which may be seen at the office. The preparations, which are free of poison or deleterious drugs, may be had as above, in pots and bottles at 5*s.*, 10*s.*, 20*s.*, 50*s.*, and 100*s.* each, with full directions, which must be used in proportion to the extent of premises infested, to successfully eradicate the vermin, and which can be applied without injury to property. Dwelling-houses cleansed from 1*l.* to 5*l.* per annum; mansions and estates from 10*l.* and upwards; ships, docks, warehouses, granaries, breweries, farms, wharfs, &c., in proportion. Caution.—None are genuine unless bearing the signature and seal "Joseph Anton Meyer."

TO COLONISTS, EMIGRANTS, &c. — MRS. MARY WEDLAKE, widow of the late THOMAS WEDLAKE, at 118, FENCHURCH STREET, CITY, informs Emigrants and others that she continues to manufacture those Agricultural Implements for which her late husband was so extensively patronised by the Settlers of South Australia, Van Diemen's Land, Swan River, New Zealand, and other British Colonies. The following articles, made in a very superior manner, are kept on sale at the London Warehouse, viz.:—

Patent Hay-making Machines	Flour-Mills—Bean-Mills
Dressing Machines	Patent Essex Ploughs, 20 sorts
Patent Chaff-cutting Machines	Scholl Ploughs [Colonial
Oil-Cake Crushers	Threshing Machines for the
Double action Turnip-cutters	Drills of all kinds—Scarifiers
Railway Wheels	Vacuum Pumps

Please to be particular in the address, MARY WEDLAKE, 118, Fenchurch Street, London.

REAL SHEFFIELD PLATED DISH COVERS, at prices hitherto unattempted. THOMAS WEST, 18, Ludgate-street, London, having received a large supply direct from the manufactory at Sheffield, offers the best Meat Dish Covers as follow:—Cottage Pattern—1 Cover of 20 inches, 3*l.* 19*s.*; 1 do. of 18 inches, 3*l.* 3*s.*; 2 do. of 14 inches, 4*l.* 8*s.*; the set of 4, complete, 11*l.* 10*s.* ONLY. Double Dome Pattern—1 Cover of 20 in., 4*l.* 10*s.*; 1 do. of 18 inches, 3*l.* 19*s.*; 2 do. of 14 inches, 5*l.* 5*s.*; the set of 4, complete, 14*l.* ONLY. In noticing the prices of the above goods, T. W. ventures to assert they are superior to many advertised at a much higher price. Best Wrought Silver Spoons and Forks as usual, Fiddle Pattern, 7*s.* 2*d.* per oz.; Queen's Pattern, 7*s.* 4*d.* per oz. Superior Watches and Fine Gold Jewellery, cheaper than any house in London. West's Hand-book, with 100 engravings, and full of useful information, is just published, and may be had gratis, and post free, on application to T. WEST, Silversmith, 18, Ludgate-street, London.

HORIZONTAL WATCHES, very flat.—A. B. SAVORY and SONS, Watchmakers, 9, Cornhill, London, opposite the Bank. Price, in silver cases, three and a half guineas each; or in gold cases, six guineas each. These Watches are accurate and durable, the horizontal escapement being peculiarly suited to combine those important requisites. They are jewelled in four holes, and continue going whilst being wound. A twelvemonth's warranty given with each.

TERRA COTTA FIGURES, VASES, FOUNTAINS, &c. Manufactured by DOULTON and WATTS, LAMBETH POTTERY, High-street, Lambeth, London.

D. and W., from their experience as Potters, have made considerable improvements in the manufacture of Terra Cotta, the superiority of which over Artificial Stone or Cement is well known. It is subjected to a high degree of fire, which renders it imperishable, and gives it a sharpness and surface which no changes of temperature can impair.

D. and W. are enabled to offer the Terra Cotta at a considerable reduction in price; and Drawings and Designs will be forwarded Gratis, on application.—Architectural work executed.

LEA AND PERRINS'S WORCESTERSHIRE SAUCE. Prepared from the Recipe of a Nobleman in the County.

"*Great Western Steam ship, June 6,* 1844.—The cabin of the Great Western has been regularly supplied with LEA & PERRINS'S Worcestershire Sauce, which is adapted for every variety of dish, from turtle to beef, from salmon to steaks, to all of which it gives a famous relish. I have great pleasure in recommending this excellent Sauce to Captains and Passengers for its capital flavour, and as the best accompaniment of its kind for a voyage. (Signed) JAMES HOSKEN."

"One of the most pleasant inventions of this luxurious and epicurean age is Lea and Perrins's Worcestershire Sauce, adapted to fish, flesh, fowl, and game, giving a zest far superior to the long-established favourites; more wholesome and of less cost."—*Naval and Military Gazette, April 6, 1844.*

Sold Wholesale by the Proprietors, Messrs. LEA and PERRINS, Worcester; Messrs. BARCLAY and SON, Farringdon-street; and the principal Oil and Italian Warehousemen in London; and Retail by the usual Venders of Sauces.

On the 1st October will [illegible]

Longman, Brown, Green, and Longmans.

LINDLEY'S KEY of Prose and Verse.

Just published, 12mo, price 5s. cloth,

A KEY TO LINDLEY MURRAY'S ENGLISH GRAMMAR.

"We have examined the present edition, which has been long out of print, and find it greatly improved and enlarged. Whatever merit the original work possessed, this edition has retained, and to it has added many valuable exercises in Parsing, Analysis, and Composition, which will render it a most valuable assistant to the student in the English language."—*London Journal of Education*

"This publication has been long out of print, but the want of it has been severely felt by many teachers. Most persons who have been long away from the study of their native tongue know how deficient they are in the facility with which kindred approaches. Mr. Richardson describes his feelings with exquisite truth and tenderness . . . Whatever work of natural challenges his preference, he views them all with poetical eye, and paints them in his verses with vividness and fidelity. We should be glad to see the poetry of these volumes separated from the prose, and sent into the world alone. It has sufficient claims for it to depend on its own vitality; and we venture to predict that it will live."—*Sunday Times*

"The essays afford some exquisite reading. We can with perfect confidence refer every man of literary taste to these volumes, which we consider an elegant and valuable contribution to the literature of our country."—*Indian News.*

"The poems are largely impregnated with Nature's best and holiest feelings. They are utterances of the writer's own heart, and they reach the hearts of his readers. They leave an impression which will not be easily or speedily effaced. The diction is in keeping with the sentiments; it is at once accurate and graceful The same observation applies to the author's prose writings."—*Observer.*

CARNATIONS AND PICOTEES

JOHN DICKSON, Acre-lane, Brixton, Surrey, has prepared for the growers of these splendid flowers a Catalogue, enabling them to make choice of their qualities, with the prices annexed, which may be had at the Nursery and of Messrs WARNER & WARNER, Cornhill, London after the 7th September

BAGSHOT NURSERY (late HAMMOND'S)

GEORGE BAKER, late of Knap-hill, has to inform his Friends and the Public, that, under an agreement entered into in July last, he has become the tenant of the Bagshot Nursery Grounds, formerly for many years occupied by Mr HENRY HAMMOND. Mr BAKER is adding considerably to the stock, rendering it superior in quality and of greater variety than has hitherto been kept at this Nursery All letters addressed to Mr BAKER, Bagshot Nursery, Surrey, will be punctually attended to.

CARNATIONS, PICOTEES, PINKS, AURICULAS, ALPINES, AND POLYANTHUS.

JOHN HOLLAND, Florist, &c, Market-place, Middleton, near Manchester, Lancashire, respectfully informs his Friends and the Florist-ulture Public that his extensive and choice collection of the above Flowers Flowers are now ready for bunding out, Catalogues of which are now ready, and may be had on prepaid application

Market place, Middleton, October 11

THE GREATEST NOVELTY EVER OFFERED TO THE PUBLIC

RHODODENDRON JACKSONII.—This splendid new hardy Rhododendron is confidently recommended as unquestionably extant surpasses in the colours of its flowers the richest Geranium, and is quite a new feature in this noble family. It forces well, is a free bloomer, and of dwarf habit. A truss of flowers was transmitted to Dr Lindley, who pronounced it "a very compact and handsome variety," with "great richness" in its general appearance, See *Gardeners' Chronicle* of the 6th April last, page 216. "*Rhododendron.—C L N.*" To be sent out in March at 10s 6d each

WM JACKSON and Co. beg leave to call the attention of the Nobility, Gentry, and the Trade, to the following rare and valuable Rhododendrons, all warranted true, at the very low prices attached. The plants are from seed, fine and stout, twice transplanted.

Rhododendron campanulatum, seedlings 1 inch, 2l per 100.

Hybrids.

Between R campanulatum and the most splendid arboreum, 2 in, 7l per 100
" " " " " 3 " 2l "
" " " " " 4 " 3l "
" " " " " strongest, 1 inch to 2 ins 7l per 100
" " " " " ditto ditto, 2 inch 7l per 100

Usual Discount to the Trade on the above.

Cineraria Celestial, No. 1, 2s 6d each, No. 2, 2s 6d each; fine plants well established. [illegible] opinion in the *Gardeners' Chronicle* of April 6th, page 216, under the letters "*C L N.*" and Advertisement of [illegible]

Wm. J. and Co. take this opportunity of [illegible] in consequence of the great success they have had in [illegible] above beautiful Cineraria, they have reduced the [illegible] will be applicable to all who have already [illegible] their orders, which will be executed next month, and [illegible] given to compensate for long carriage.

These new Calceolarias have resulted from [illegible] fine white and canary Rhododendrons, and [illegible] application, A remittance or reference [illegible] unknown correspondents.

Agents in London: Messrs. Groom, Grosvenor and Covent[illegible] Nurseries, who have seen the plants.

Cross Lanes Nursery, near Guisley, Yorkshire, Sept. 28.

THE NEW SUPERB SEEDLING PICOTEE,
"BURROUGHES'S DUKE OF NEWCASTLE."

YOUELL & CO have much pleasure in announcing they will send out for the first time the above splendid light edged purple Picotee raised by the Rev J Burroughes It is guaranteed to surpass many Purple Picotee that has yet been raised Without commenting further upon its superiority, Y and Co. beg to refer to a report in a late No of the *Gardeners' Chronicle* as follows —

"The *Duke of Newcastle* is a flower of first rate properties, it is a light edged purple the petals are large, and of good form and substance, even on the edge; the colour unbroken; the pod good, and with less disposition to burst than is common" It obtained the first prize, as the best seedling, at the Norfolk and Norwich Horticultural Exhibition Price 21s per pair The stock being limited, to prevent disappointment early orders are respectfully requested Y & Co are also enabled to supply the following superb Picotees, raised by the same gentleman, all possessing first rate properties and have been exhibited and obtained first class prizes at several of the metropolitan Exhibitions of the present year They are as follow —

Burroughes's Mrs Benyon, Red Picotee	7s	6d
" Lady Alice Peel, Rose Picotee	7	6
" Miss Jane, Purple Picotee	7	6
" Mrs Bevan Red Picotee	7	6
" Enchantress, Scarlet Picotee	5	0

CARNATIONS AND PICOTEES.

Y and Co's collection of this beautiful tribe of flowers will be found the most extensive and select in Europe, comprising every known variety of merit The plants are remarkably strong and healthy and ready for sending out to any part of the United Kingdom and the Continent at the following prices

				£	s	d

TRAINED PEACHES AND NECTARINES

WM. E. RENDLE respectfully informs the Nursery Trade that he has this season a large stock of TRAINED PEACHES AND NECTARINES, strong, healthy, and in excellent condition.—Union road Nursery, Plymouth, Oct. 7, 1844.

NEW CARNATIONS, PICOTEES, AND PINKS.

MESSRS. N. and T. NORMAN'S CATALOGUE of these FLOWERS can be had on prepaid application.—Bull Stake, Wrotham.

KINGHORN'S SEEDLING CALCEOLARIAS.—In answer to numerous inquiries, T. KINGHORN begs to inform the Public that Mr. Oakley purchased the entire stock of the following varieties, viz., Duchess of Sutherland, Lady Ann Chetwode, Rosamond Wilson, and Kinghornii, exhibited by T. K. at the Horticultural Gardens in May, and the first two at the Royal Botanic Gardens in June. See *Gardeners' Chronicle*, May 25th, page 324, and Mr. GLENNY's opinion of them in the *Gazette*, page 413; also in answer to a correspondent in the *Gazette* of last Saturday. F. R. K. had the sole management of Mr. GLENNY in selecting the above from his numerous seedlings previous to the Exhibitions. Nevertheless, the flowers in possession of Messrs. MAY and GAINES are very fine desirable varieties.—Twickenham, Oct. 11, 1844.

DOUBLE ROMAN and PAPER-WHITE NARCISSUS, 4s. per dozen. The above Bulbs, the former of which is so justly esteemed for its early blooming and excessive fragrance, and the latter for its purity and elegance, have been just received from CORBETT'S, late MR HARRISON'S, Italian and Foreign Warehouse, 18, Pall Mall. Also Dutch Hyacinths, Crocus, Tulips, Anemones, &c. &c. Price Catalogues of which may be had *per* Post.

TULIPS, HYACINTHS, RANUNCULUSES, ANEMONES, GERANIUMS, AURICULAS, CARNATIONS, and LILIUM LANCIFOLIUM.

HENROOM, Clapham Rise, near London (removed from Walworth), by Appointment Florist to HER MAJESTY, begs to recommend to the attention of the Nobility, Gentry, and Public his extensive assortment of the above Flowers, which, from the success he has had in their cultivation, he can offer at very moderate prices. He particularly wishes to call attention to the highly-flattering remarks on his Exhibitions of Tulips and Lilium lancifolium this season, in the various papers. He is also desirous of reminding the Nobility, Gentry, and Amateurs, who may wish to add to their collections or ornament their gardens with these beautiful flowers, that this is the best season to make a selection. The varieties of the splendid Lilium lancifolium are particularly adapted for parterres, &c., besides being quite hardy, they flower at a time when the Nobility and Gentry are at their country seats, and when flowers are so much wanted. They only require to be known to be universally cultivated. Catalogues can be forwarded by post on application. Foreign orders executed.

GERANIUMS AT VERY LOW PRICES.

WM. E. RENDLE, having a large stock of the following sorts of GERANIUMS, is enabled to offer them at very low rates:

*** A dozen will be forwarded on receipt of a Post-office order, including hamper, package, and carriage free to the Exeter terminus of the Great Western Railway.

CLASS 1.—6*s.* per dozen, including package, carriage, &c.—Ohe Regnarlier, Pulchellum, Jersey Maid, *Lady Villiers*, Fascination, Diamond of Kendle, Symmetry, Tomaseer, Dido, Cordelia, Oberon, Fuvourite, Prince of Waterloo, Jessie, Count D'Orsay, Lord Eldonian, Gastellation, Lavinia, Coreish Gem, Attila, Rival of Dispersal, and Symmetry.

CLASS 2.—9*s.* per dozen, including package, carriage, &c.—Eraline, Gipsey, Wish, Hamlet, Cynthia, Aurora, Creole, Lady Cotton Sheppard, Countess of Mount Edgcumbe, Fair Maid of Devon, Wonder of the West, Portia, Jupiter, Life-guardsman, King John, Sultan, and Princess Royal (Lyne).

CLASS 3.—15*s.* per dozen, including package, carriage, &c.—Camilla, Consort, Van Amburgh, Enchantress, Glory of the West, Ivanhoe, Flash, Queen of the Fairies, Grand Monarch, Sanchyar, Wildfire, Mabel, Prince Albert, Nymph, Bridegroom, and Spital.

All the plants are strong, healthy, and well established, and will be forwarded immediately on receipt of invoice.

Union Road Nursery, Plymouth, Oct. 7, 1844.

SUPERB SHOWY SEEDLING CINERARIAS, for this autumn and winter flowering.

Dwarf, bushy plants, well trussed for bloom, in 24-sized pots, 18*s.* per dozen.

Do. do. in 48-sized pots, 9*s.* per dozen.

The above can be confidently recommended as being saved from the very choicest and most superb kinds, comprising every shade of beautiful light and dark-blue tints, and admirably adapted for the furnishing of the greenhouse or drawing room, throughout the autumn and winter months. Seed selected from the same, 2*s.* 6*d.* per packet.

THUNBERGIA CHRYSOPS.—Plants of this beautiful Creeper, rich purple flower, with golden eye, 7*s.* 6*d.* each.

M. S. has a large stock of the following STRAWBERRIES:—

Myatt's British Queen	6*s.* per 100.
Do. Elisa	6*s.* ,,
Emperor, variety from Keen's Seedling	3*s.* ,,
Grape-flesh Pine, small fruit, fine flavour	3*s.* ,,
Elton Pine	20. 6*d.* ,,
Keen's Seedling	2*s.* 6*d.* ,,

Applications, including post-office orders, will be immediately and carefully executed, addressed to MICHAEL SAWERS, Sen., London-road Nursery, Cambridge.

HERTFORD NURSERIES.

E. P. FRANCIS begs respectfully to inform the Nobility, Ladies, and Gentry, that his descriptive CATALOGUE OF ROSES will be ready for delivery on and after the 10th of October, and will be forwarded gratis upon application, and which comprises upwards of a thousand varieties.

E. P. F. takes this opportunity of stating that he has made an addition of several acres of land, and that his Nurseries now extend over 25 acres of ground, containing a large stock of Fruit and Forest Trees, which are in fine and healthy condition; a fine assortment of Trained Trees, Evergreens, and Flowering Shrubs, all of which may be had upon the most reasonable terms. Catalogues may be obtained with Prices attached. Carriage of all goods paid to London.

NEW PLANTS.

MESSRS. VEITCH AND SON have now ready for sending out the two undermentioned beautiful New Plants, viz.:—

MANDEVILLA VIOLACEA. Flowers of a rich violet colour. It is figured by Dr. LINDLEY, in the "Botanical Register" for August last, who there says—"The Mandevilla violacea is one of the finest things obtained from South Brazil. It has been introduced by Messrs. Veitch and Son, of Exeter, who received for it their large Silver Medal at the Horticultural Society's Garden exhibition in May last. It will doubtless prove a very valuable addition to the Greenhouse Plants; and is certainly unsurpassed by any of the climbing flowering shrubs."

CLITORIA PULCHRA. Strong plants of this fine plant were exhibited at Chiswick, in May, under the name of *Clitoria* species, and received the Knightian Medal. See *Gardeners' Chronicle* for May 25. It is figured in "Edwards's Magazine" for July last.

Messrs. V. and Son have also to offer the following New Plants, viz.:—

Anthurium picta	Gardenia [illegible]
Allamanda grandiflora	,, Lucyniana
Barbacenia squamata Veitchia	Gesneria [illegible]
Clerodendron infortunatum	Gloxinia Barkerii
,, splendidum	Hedisia longifolia
Cyrtoceras reflexa	Impatiens [illegible]
Echites atropurpurea	Lasiandra [illegible]
,, insignis	Pleurothera [illegible]
,, splendens	Tecoma [illegible]
Franciscea Hopeana	Thunbergia chrysops, &c. &c.

N.B.—Messrs. V. and Son's General Catalogue can be had on application.—Exeter, Oct. 11, 1844.

JOHN SLATER, Florist, Chatham Hill, near Manchester, respectfully solicits the attention of the Horticultural Public to his extensive collection of the following Florists' Flowers, viz.:—PANSIES, POLYANTHUSES, CARNATIONS, and PICOTEES; catalogues of which may be had on prepaid application. His stock of named Auriculas, of different varieties, for pots, pictures included, 36 pairs of Carnations and Picotees, good named varieties, for 36*s.*, package included.

NEW SEEDLING AURICULAS AND CINERARIAS.

WM. IVERY, Florist, &c., Kensington, near London, begs to inform the Nobility and Gentry that he is ready to supply the undermentioned Plants, which he can with confidence recommend:—

AZALEA LATERITIA ROSEOLA, bright rose, 21*s.* to 31*s.* 6*d.* each. "A Certificate of Merit was awarded to Mr. Ivery, at Kensington, having large flowers, sleps and bright in colour, and expanding freely."—DR. LINDLEY in *Gard. Chron.*, April 20.

AZALEA COCCINEA SPLENDENS, bright scarlet, good shape, and free bloomer, 15*s.* each; Azalea delicata, bright pink, good shape, and abundant bloomer, 15*s.* each.

CINERARIAS.—Beauty of Wobburn, very large white beautiful eye and dwarf habit, 5*s.*; tricolor, white and pink, brown eye, compact flower, 5*s.*; Nosegay, purplish blue, good petal, and noble truss, 5*s.*; Washington, very large crimson, good petal, 5*s.*; Captivation, white ground, with beautiful mazarine purple tips, gained first Prize at the West Kent June Exhibition, 5*s.*; Criterion, mazarine blue, beautiful white centre, gained first Prize at Dorking May Exhibition, 7*s.* 6*d.*; Red Rover, bright crimson, beautiful prolific bloomer, 5*s.*; Fanny Eisler, white crimson tips, prolific bloomer, 5*s.*; Pickwick, bright purple large flower, and fine shape, 3*s.* 6*d.*; Compacta, small, white, and beautiful round flower, 5*s.*

The whole set of Seedling Cinerarias, 21*s.*

The following CINERARIAS can be recommended as good:—Ivery's Beauty of Syston, bronzy purplish blue, fine winter flowering var., 3*s.* 6*d.*; Emperor, 2*s.*; Pride of Peckham, 2*s.* 6*d.*; Regulata, 2*s.*; Delicata, 1*s.* 6*d.*; Regina Victoria, 2*s.* 6*d.*; Triumph, 2*s.*; Rival King, 1*s.*; Imperial Blue, 1*s.*; Royal Blue, 1*s.*; Iveryana, 1*s.* 6*d.*; Princess Royal, 1*s.* 6*d.*; Queen Victoria, 1*s.* 6*d.*; Exquisite, 3*s.* 6*d.*; Wee Pet, 3*s.* 6*d.*; Henderon's Azurea, 1*s.* 6*d.*; Pilot, 1*s.* 6*d.*; Unique, 1*s.* 6*d.*; Magnet, 1*s.* 6*d.*; Prince of Oldenburgh, 3*s.* 6*d.*; Sombre Agreeable, 2*s.* 6*d.*; Eclipse, 1*s.* 6*d.*; No. 7, 1*s.* 6*d.*; Enchantress, 1*s* 6*d.*; Compact Blue, 1*s.* 6*d.*; Bell's Decora, 1*s.* 6*d.*; Good's Compacta, 2*s.* 6*d.*; Gaines's True Blue, 1*s.* 6*d.*; Prince Albert, 1*s.* 6*d* ; May's Queen of May, 2*s.* 6*d.*; Youngii, 1*s.* 6*d.* Good varieties from 9*s.* to 18*s.* per doz. Fine Cineraria Seed, 2*s* 6*d.* to 5*s.* per packet.

Fine PETUNIA, noticed in "Calendar of Operations," *Gard. Chron*, Sept. 14. Ivery's Pet, 1*s.* 6*d.* to 2*s.* 6*d.*; Magna Charta, 1*s.* 6*d.* to 2*s.* 6*d.*; Reliance, 1*s.* 6*d* to 2*s.* 6*d.*; Ovid, 1*s.* 6*d.*; Prince Albert, 1*s.* 6*d.* to 2*s.* 6*d.*; Kentish Beauty, 1*s.* 6*d.*; Enchantress, 1*s.*

WARREN'S GARDEN and NURSERY, Nonantum Vale, Brighton, Floral Saloon and Seed Store, No. 1, Tremont Temple (late Tremont Theatre), Boston.

The Proprietor of this Establishment is now ready to receive and execute orders for Fruit, Ornamental Trees, Grape Vines, Shrubbery, Roses, Strawberry Plants, &c., in any quantity, and of the most valuable kinds, at short notice, properly packed and secured for transportation to any part of the United States, Provinces, or Europe.

The Catalogue for 1844, which has been prepared with scrupulous care, contains a list of the choicest sorts of Pears, Apples, Plums, Cherries, Peaches, Apricots, and Nectarines, Grape Vines, Raspberries, Gooseberries, Strawberries, Currants, Evergreen Trees and Shrubs, Ornamental Trees, Herbaceous Plants, Roses, Greenhouse Plants, Dahlias, &c.

A new feature has been added in the Catalogue, which renders it particularly valuable for purchasers who are desirous of improving their orchards and grounds, by planting only the most approved, superior, and productive varieties. It is by columns and abbreviations, the meaning of which is explained under every different kind of fruit, so that a large number of the most important characters by which the different varieties are distinguished may be seen at a glance.

While the List of Fruits may not be found so extensive as in some other Catalogues, it contains every kind of value, and all new and improved varieties are added as soon as their qualities are tested. Nevertheless, any variety that may be ordered can always be supplied, on as reasonable terms as are afforded at other Nurseries.

The List of DAHLIAS comprises upwards of 300 of the choicest varieties of this gorgeous and splendid flower, most of them prize varieties. Dry Roots ready for delivery early in the Spring, and in Pots from the middle of April to the 1st of June.

STRAWBERRIES, of the most productive and best varieties, for sale, in any quantity. None but healthy and strong Plants will be suffered to leave the Nursery.

GRAFTS and SCIONS of most of the kinds named in the Catalogue, can be obtained in their season.

GREENHOUSE PLANTS of all the rare and splendid kinds always on hand at the Saloon, where visitors are respectfully invited to call.

GRAPE VINES, ASPARAGUS, and other roots constantly for sale.

Also, a great variety of choice GARDEN and FLOWER SEEDS, all of this year's growth, and warranted fresh, genuine, and true to their names.

Agricultural, Horticultural, and Botanical Books.

Gardening Implements, Flower Vases, &c. &c. The whole enumerated in a new descriptive Catalogue, which will be given Gratis on application. All orders for trees will be delivered at one day's notice. Every tree and plant will be warranted by the subscriber as to its distinctive character and goodness,

JAMES L. L. F. WARREN.

NEW HARDY TRIBES.

SUTTON AND SONS respectfully recommend attention to this beautiful tribe, and especially to the elegant and distinct varieties which they have of late years imported.

Burrow and Sons' Collection of Irises are equal to any in Europe, and they now offer as under:—

The Collection of 36 varieties	1*l.* 10*s.*
The most distinct 40 do.	2 2
The best 12 do.	1 0

The readers of the *Gardeners' Chronicle* are earnestly recommended to observe Messrs. SUTTON'S Priced List in the 32 Page of the *Chronicle* of 28th September.

N.B.—Parcels delivered free to any of the railway and packet offices in London, or any station on the Great Western Railway within 60 miles of London.—Reading Nursery, October.

GEO. MILLS offers Five Seeds of his best Frame CUCUMBER for 2*s.* 6*d.* His Treatise on the [illegible] with Plan of Pit, is published, 4*s.* 6*d.*, Price [illegible] publish price 2*s.*, his Experimental [illegible] Also, his Opinion of the Dahlia [illegible] Shrubbery Park, Acton.

ROSES.

[illegible] begs to inform his [illegible] published his Price Cur[illegible] [illegible] nent containing [illegible] and Climbers [illegible] [illegible] [illegible]

SPALDING'S EKOLIPTIC RED WHEAT, DUTCH ROOTS, &c.

JAMES C. WHALLEY begs to inform their Friends and the Public that they have a large supply of the above very valuable Wheat, and having received the most flattering reports in its favour from several eminent Agriculturists who have grown it, they feel great confidence in recommending it as the best Red Wheat now grown, having during the last two seasons in a great many instances produced above 60 bushels per statute acre; this season many fields have yielded the enormous quantity of 7 quarters per acre, and where grown in competition with other sorts of Wheat, it has produced 6 to 12 bushels more per acre. Price 9*s.* 6*d.* per bushel.

J. and C. W. have also ITALIAN RYE-GRASS, imported direct by themselves, and which has given such great satisfaction the last year to their friends. New Winter Tares, Seed Rye, &c. &c.

A fine collection of Imported DUTCH ROOTS, priced Catalogues of which may be had on application.

A general assortment of AGRICULTURAL IMPLEMENTS, embracing every article of acknowledged merit as it appears.

St. George's Crescent, Liverpool.

DANECROFT NURSERY, STOWMARKET, SUFFOLK.—PETUNIAS, SEEDLING VERBENAS, DAHLIAS, &c.

C. GIRLING has much pleasure in announcing to his Friends and the Public generally, that he has been successful in adding to his already extensive collection of Verbenas some splendid Seedlings of the present year, which for colour, form, and size far surpass any Verbenas yet produced; in confirmation of which C. G. begs to refer the public to the following awards they have received, and reports that have been made of them, viz., an Extra Prize at the Ipswich Show in June, Stowmarket in July, Ipswich in September, Bury St. Edmunds, &c., Newmarket, &c., and Chelmsford open Show; and favourably noticed by the Conductor in the *Gardeners' Chronicle*, August 31, and in the *Gardeners' Gazette* by Mr. Glenny, August 31. Mr. Ayres also speaks of them in flattering terms in the *Gardeners' Chronicle*, Oct. 5, page 613; and in addition to the above testimonials they have been seen growing by many eminent Horticulturists and Amateurs, all of whom have considered them as very superior.

S. G. therefore offers them with full confidence of their giving general satisfaction.

	s.	*d.*
Alba Lutescens, sulphur-yellow, large, and sweet-scented	3	6
Alba Magna, the largest and best white out	3	6
*Blanda, rosy-blush of excellent form	3	6
*Gladiator, orange-scarlet, with deep yellow eye, fine	3	6
Lovely Rambler, grey-lilac, very large	3	6
Messenger, bright-purple, of fine shape	3	6
*Mulberry, bright-mulberry, quite new in colour and fine	3	6
Rose de Amour, bright-pink, with beautiful yellow eye, quite distinct, and the most attractive Verbena ever raised	5	0
*Rubescens, bright-ruby, large and well-formed	3	6
The Giant, silvery-lilac, the largest trussing Verbena known, some of the trusses measuring from 10 to 12 inches in circumference—the heads of this Verbena resemble in appearance a blue Hydrangea	5	0

N.B.—Those marked with an * will not be sent out till early in May; the others can be had after the 25th of October, and can be forwarded in tin boxes by post. The usual allowance to the Trade.

PETUNIAS.—S. GIRLING has likewise been successful in raising some Petunias of superior excellence. Twelve varieties, selected from about fifteen hundred seedlings, will be sent out as early as possible in the spring, far surpassing anything in that fine and beautiful class of plants. Nurserymen wishing to be appointed agents are requested to forward their names, which will be published in the *Chronicle* and *Gazette* before sending out. The usual allowance to the Trade. Advertisements with names and prices will shortly appear.

DAHLIAS.—S. GIRLING having purchased the entire stock of that beautiful Dahlia, Bourne's Marchioness of Ormond, the best light-tipped Dahlia of the season, similar but far superior to Bridesmaid in every respect, plants will be sent out early in May next, at 10*s.* 6*d.* each. A few roots would be parted with, on the warranty of the party purchasing, *for* exportation only, and the party to whom sent giving a pledge not to send plants to England for sale. Nurserymen and dealers wishing to place this Dahlia in catalogue next season, will have their names published in good time before sending out, and the usual Trade allowance, where 12 Plants are ordered, and extra Plants to compensate for long carriage.

DAHLIA NONPAREIL.—S. G. has a few large and small ground roots of that beautiful and popular Dahlia to dispose of; the former at 20*s.*, the latter at 10*s.* each. From the limited number sent out in England last season of this Dahlia, it will be more in demand than any other Dahlia sent out last May. Parties wishing for roots had better send their orders early, as the stock, which is limited, will be sent out in rotation, as the orders are received; almost every other kind of Dahlia in cultivation, embracing nearly all the favourite varieties of this and former years, can be had in dry roots at moderate prices, warranted correct to name.

N.B. A respectable reference or ready money will be required from unknown correspondents.

Foreign Orders faithfully executed.

Danecroft Nursery, Stowmarket, Suffolk, October 10, 1844.

LARGE IRISH YEW.—If any person has a large Irish YEW, not less than seven feet high, to dispose of, a purchaser may be found by addressing Mr. MARNOCK, Exotic Nursery Garden, Canterbury.

PRINCESS ALICE MAUDE, AND [illegible] STRAWBERRIES.

HURST AND M'MULLEN, 3, Leadenhall-street, London, beg to inform their friends that they have a few fine plants of the above celebrated kinds of Strawberries still remaining, at 30*s.* per 100: also fine plants of Myatt's British Queen, &c. at 6*s.* per 100; Alpinella imbricata, strong plants, 6 inches high, 2*l.* per 100. Their Catalogue of Dutch and Cape Bulbs can be had on application; it contains splendid collections of Ixias, Gladiolus, Sollias, &c. &c.

CINERARIA "SILVER QUEEN."

A. PAUL AND SON, Nurserymen, &c., Cheshunt, Herts, beg to offer the above novel and beautiful Cineraria, which was exhibited at the Horticultural Society's Garden, Regent-street, May 21, 1844, and received a certificate there.

It is a tricolor and handsome trussing Cineraria, showing a [illegible] to quill, by the petals [illegible] of the flower being [illegible] for some distance from their bases, and thus [illegible] a silvery appearance.—*Gardeners'* [illegible]

Messrs. [illegible] Paul and Son [illegible] a Cineraria, [illegible] of a [illegible] and singular silvery [illegible]—*Gardeners' Gazette*.

Plants now [illegible] for [illegible] packings, or post [illegible] An order [illegible] from [illegible] expected from [illegible] correspondents. [illegible] discount to the Trade on all plants.

SUPERB [illegible] CINERIAS, 24*s.* to 30*s.* per [illegible] [illegible] 12*s.* to 18*s.* ditto. [illegible] PAUL and [illegible]

[illegible] [illegible] [illegible] [

THE TRUE FASTOLFF RASPBERRY.

YOUELL AND CO. beg to announce they will again be able to supply fine canes of the above truly excellent variety, unequalled for the size of its Fruit, and richness of flavour; prices as follow:—

Packages containing	100 Canes	.	£3	0 0
Ditto	50 "	.	1	1 0
Ditto	25 "	.	0	12 0

Further particulars will appear in future Advertisements.

YOUELL and Co. feel it due to themselves to state that a spurious kind was offered for sale by other parties last season, under the title of "Fastolff Raspberry," the same having no pretensions to the genuine variety.

Great Yarmouth Nursery, Oct. 10, 1844.

The Gardeners' Chronicle.

SATURDAY, OCTOBER 12, 1844.

MEETING FOR THE TWO FOLLOWING WEEKS.

WEDNESDAY, Oct. 16	Microscopical	8 P.M.
SATURDAY, Oct. 26	Royal Botanic	4 P.M.

Is there half a dozen persons who ever looked into that most curious book, "A Philosophical Treatise of Husbandry and Gardening; being a New Method of Cultivating and Increasing all sorts of Trees, Shrubs, and Flowers. By G. A. Agricola, M.D., and Doctor in Philosophy at Ratisbon," of which an English translation appeared in 1721? We doubt it. And we presume that the few who have ever looked at it have closed it again with the conviction that it is an imposition from beginning to end. There are, however, things in that book which laid the foundation of the most recondite processes employed in the MULTIPLICATION OF PLANTS. Agricola may indeed be regarded, notwithstanding his lies and exaggerations, as the father of the art and mystery of propagation. He maintained that all plants may be multiplied by portions of every part of the stems, leaves, and roots.

"A query," he says, "was once proposed in an assembly, viz., *An detur modus artificialis universalis multiplicandi arbores et frutices distributivè sumptos?*—Whether there be such a thing as a universal way of multiplying trees and shrubs in a distributive sense? There was one who presently answered that such a thing might be reckoned among the *Non entia*, and was such another fiction as that of Bellerophon; but I hope I shall, through care and diligence, bring the matter so far as to convince those incredulous persons, not by words only, but by real experiments." And then he goes on to explain how such ends are to be attained.

His great panacea was what he called Vegetable Mummy, a mixture of gum copal, and Venice turpentine, into which the fragments to be operated on were to be plunged. And a hasty reader would suppose that this was all that Dr. Agricola relied upon. But the true principles of multiplication were well understood by him, and distinctly explained; his mummy was only an accessory in the operation. Take, for example, the following passages:—

"'Tis certain, from a great many experiments, that a yearly joint or shoot has in itself at the same time both root and branches; and, according as things are managed, it quickly produces either a twig or a root. To demonstrate this, I shall pitch upon an instance known to all country people and Vine-dressers; they take a long stalk or branch of Vine that has a great many joints, which they bend under ground, and it shoots a great number of roots on every side; now had they not bent that branch thus under ground, other new branches would have come out of its joints, which is not at all to be questioned; but if roots may grow from one shoot or branch, they may likewise grow from all, when skilfully prepared, as experience has shown, and new discoveries will confirm. Therefore what has been said of one shoot will be found true of all.

"It has been already demonstrated, that every tree is furnished with abundance of joints, in which lies the spring of life. You may take a branch with two or three joints, and cut off the wood at the bottom of each, according to art, which being done, you may dress and lay them under ground. But as there are on every branch above fifty or threescore joints, which may all be treated after this manner, it follows that the same method may be used with respect to all trees and shrubs, although they have a hundred thousand or a million of joints."

Here we have the main principles of propagating plants as plainly described as they could be at the present day. A more learned phraseology might be employed, but the meaning would be the same. In the course of a century we have not advanced a step, except that we can do without mummy what Agricola says he did with it.

It is certainly true that every joint of every plant will form a new plant, if placed in circumstances favourable to maintaining its vitality long enough to enable it to take root. The difficulty consists in knowing what those circumstances are, and how to insure their presence. An experienced propagator knows this—one without experience is ignorant of it. Both have the same rules and facts to guide them, but one cannot apply them and the other can. In one man's hands every cutting strikes; in another's they all die. What one pronounces it impossible to propagate at all, another never fails with. Give Schykoffsky a willow *leaf* and he produces you a couple of plants; give Grumble a willow *branch*, and he contrives to kill it.

The English, with all their skill as gardeners, are certainly not the most celebrated as propagators; for although we here and there find a first-rate hand among them, yet he forms the exception, and not the rule. We once knew a man who flattered himself that he was a capital gardener because he grew Grapes pretty well; and yet, when the cone of a Pine-tree was given him, the only notion he had of obtaining any live thing from it was to sow it whole as he received it. This honest man might be a Grape-grower, but he was no gardener. It is true that he wore a blue apron, and talked much *about himself* at village meetings, but the unlucky Pine-cone showed him up. When the ass put on the lion's skin, he would have passed as the very monarch of the forest if his braying had not betrayed him.

Now the science of propagation is one of the finest parts of gardening. It is the most pregnant with useful consequences, and it is the surest test of real knowledge of the profession. The man who can propagate well cannot cultivate ill. If he knows enough to do the one well, he knows too much to do the other ill. We should therefore set down dexterous propagation as one of the best practical evidences of what a gardener is good for. It is for this reason that it seems worth while to point out, as far as we have the means of doing so on paper, the views of the best modern gardeners upon this important subject; for which purpose we shall next week offer some remarks upon the recent pamphlet by Mr. Neumann, "Upon the Art of making Cuttings."

ON THE GROWTH OF FOREIGN PINES IN MORAYSHIRE.

Of the various species of Coniferæ which have been introduced into this district during the last twenty years there are none that advance so satisfactorily, or promise to become such valuable timber-trees, as those indigenous to the mountains of India—namely, Abies deodara, Pinus excelsa, and Abies Smithiana or Khutrow. These are not only of rapid growth, but they ripen their shoots so as to withstand our severest winters, and as yet, appear less liable to disease than many other Pines recently brought under our notice. The Abies Douglasii and the Pinus ponderosa, from the banks of the Columbia, are both of luxuriant growth, but are not adapted to our climate. The former has a propensity to produce autumnal growths, which, from their succulent state, are not fitted to resist severe frost, and appears to partake considerably of the nature of the Picea balsamea, a tree less tenacious of life than any other Fir. All our finest specimens of Pinus ponderosa have become victims of the small but destructive beetle, Hylurgus piniperda, and the tree is neither likely to become valuable nor ornamental. Many of the other species of Foreign Pines are either too tender or of too slow growth in this climate, and in exposed situations are not expected ever to exceed the size of tall shrubs. It is true that the more rare and expensive sorts are not unfrequently disfigured and retarded in growth, by being long confined in garden-pots before being placed permanently in the open ground—treatment which, at first, is apt to conceal the merits of the plants. It is, however, necessary to keep some kinds in pots, to insure their being removed of a certain size with safety; for instance, the Pinus maritima, and all of the same habit of growth, do not transplant and succeed well if allowed to remain more than one year in the seed-bed; that their roots may therefore be preserved in a fit state for removal they must be transplanted frequently, or kept in pots until they be placed in their final destination. This mode of treatment, however, is not necessary for the kinds we recommend from the Himalayas—their roots being very fibrous, or bushy, adapt them for being removed at almost any age when planted; and they may be successfully grown from seed by the nursery treatment suitable for the Larch and Scotch Fir. Those that we have seen kept long in pots become stinted, but the vigour which the plants assume when their roots are set at freedom in the open ground after being cramped and restrained in garden-pots is very remarkable. My remarks on the native Pines of India are not founded merely on the success of a few nursed specimens, grown under circumstances unusually favourable. Plants have been raised here in great numbers, and many have been transplanted among the brown Heath on the acclivities of some of the hills in the highest parts of the county. Perhaps the landowners of no district in Britain are better furnished with the Pines of India than are those of Morayshire—thanks to our townsman, Dr. Falconer, who collected and forwarded the seeds of the plants, which advanced so hopefully. Seeds of the Deodara presented by him are being grown to decorate the promenades on the County Hill in the vicinity of Forres, and the property of the town. The introduction and extensive propagation of trees that are natives of climates, possesses an interest and advantage to the district which is local. These form a foundation of individual wealth and independence, and become sources of national prosperity and riches. The Deodar is already the most celebrated coniferous tree of the Himalayas; it attains the height of 180 feet, with a corresponding size in circumference, or even more, and in its native country rarely falls short of these dimensions. Its wood is very compact, resinous, and fragrant, capable of receiving so very high a polish that it has been compared to brown agate, and it has been found perfectly sound in the roofs of temples in India which could not have stood less than 200 years. The average yearly growth of the plant four or five years old in Morayshire, is from 10 to 12 inches; the feathery lightness of its spreading branches, and the beautiful silvery hue of its leaves, render it even when young extremely ornamental; and all travellers who have seen the tree full-grown in its native country, agree that it unites an extraordinary degree of majesty and grandeur with its beauty.—*J. Grigor, Forres Nurseries.*

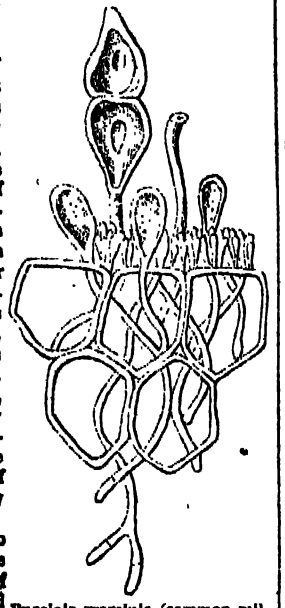
THE NEAPOLITAN VIOLET.

THIS is one of our loveliest winter flowers, if rightly managed, but this I fear is seldom the case; and the failures which take place are, I apprehend, chiefly through acts of overkindness. *Forcing*, in the strict sense of the word, will by no means agree with them, more especially by bottom-heat in the dead of winter: and this, for two important reasons: 1st, they are impatient of any given temperature above 50°, in the comparative absence of light which we experience through November and December; and 2d, because they are equally impatient of dampness of atmosphere, and this must of course occur if there be any matter beneath them in a state of fermentation unconfined.

I planted a four-light pit with them in the first week of September; this pit had been a receptacle for Pines through the summer, and was of course nearly exhausted: having trod it firm and filled it as high as would cause the Violet leaves to come within an inch of the glass, I placed thereon an inch of the richest old rotten manure in the yard; on this the violets were placed, with all the ball of earth that could be made to adhere to them, and then filled up with a compost of one half sandy heath soil in a mellow state, and the other half the top of an old Cucumber bed, which had been soiled with stiff yellow loam. The bottom-heat of this bed has descended gradually from 75° to 68° up to this time, and in another fortnight will be down to 60°; in the meantime I have kept the atmospheric heat as low as possible, by giving abundance of air all night; so that I will venture to say that the bottom-heat has averaged at least 12° more than the atmospheric heat. My plants now look splendidly, and I make no doubt will fully answer my expectations, as I am always successful with this flower. I put heath soil about them for the same reason that early Cucumber growers use it, viz., as being dryer and mellower on the surface, and somewhat antiseptic. These plants are peculiarly liable to a rottenness in the leaf, which is, no doubt, contagious, for if not picked off it spreads like wildfire, and after picking I invariably dredge a mixture composed of very coarse river sand over them, with which a little charcoal dust and quick lime has been blended. This dressing also prevents the slugs from committing their ravages, for if permitted they will constantly deface the blossoms.

Another precautionary measure is, to take care that the soil, at planting, is of an equal moisture throughout, as but little water can be used after planting, without producing too moist an atmosphere. I have up to this time used nothing but the syringe, except at planting-time, when I watered them freely to settle the soil. They must have all the air that can possibly be given with safety, both night and day; taking care at all times to exclude even the slightest degree of frost; double matting in winter, with plenty of dry Wheat straw thrown over the mats in weather of great severity, will be found sufficient for this purpose, provided the sides of the pit be completely cased with dead lining up to the lights.

The main principle to bear in mind is, the endeavour to lengthen as it were our summer, by the bottom-heat, at planting; the very discrepancy between the bottom-heat at this time, and the atmosphere, combined with the temporary check on removal, induces the blooming habit very shortly; after which the mere exclusion of frost will insure a continual production of blossoms until May of the following year.—*Robert Errington.*



DISEASES OF PLANTS.—No. IV.

[FUNGI.]

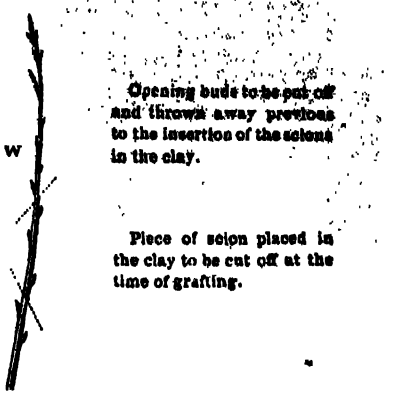
WE now come to the second great class of Fungi, viz., that in which the reproductive bodies are contained in sacs, whether they be solitary, or arranged according to some definite plan. To this belong the tribe of Helvellas and Pezizas, amongst which the common morel, or the large dunghill Peziza will at once occur to every cultivator who has taken pains to examine the structure of such species, which do not indeed require a very high magnifying power. With these are associated many subterranean forms, such as the edible Truffles, a portion of the hypogæous Fungi being more nearly allied to the puffballs. The curious Fungus, too, which grows on the hoofs and horns of animals, or upon feathers, though so closely resembling one of the small Lycoperdons, must take its place in this division. Then comes the enormous genus Sphæria, more numerous, perhaps, even than the Agarics, a familiar example of which is afforded by the Sphæria hypoxylon, which grows at the bottom of old stakes, &c., resembling the snuff of a candle. And of these also there is a small but highly interesting subterranean group, of which one or two species have been detected in this country. To this division also belong the Fungi which produce the white mildews on Peas and Roses, and that which is sometimes so destructive in Hop-grounds; and lastly, that portion of the moulds which produce their reproductive bodies within distinct sacs, or as they are called, sporangia. As stated above, the true affinities of several genera are not at present

ascertained, and precautions and notions and habits, in spite of better information, will still keep others in very improper situations. Into these questions, however, it will not be necessary to enter, at any rate for the present.

We must now say a few words on a very important constituent part of Fungi, to which attention has not always been paid—I mean that part known under the name of Spawn, or Mycelium, which produces the fruit. In general, the portion of the Fungus which appears externally, and to the casual eye, the whole Fungus, is the fruit—a fact which has given rise to the notion that Fungi consist entirely of fructification, and has caused them to be compared with such phænogamous plants, which indeed are perfectly analogous, as Hydnora and Rafflesia. But this portion often exists, even for years, without producing fruit, and either in its normal state, or one of excessive luxuriance, gives rise to various supposed genera, which, as they are destitute of fruit, and are mere states of *transition*, or what have been called anamorphoses (that *is*, over-luxuriant but incomplete conditions) of higher species, will be studiously excluded from systematic arrangements by every philosophic botanist, though they are far from being devoid of interest in other points of view. And even where the fruit has been fully formed and passed through its several stages from the first bud to ultimate decay, the mycelium itself remains to produce again, so soon as circumstances favour the peculiar combination of atmospheric phenomena necessary for their development, a fresh crop of fruit. It is thus that the largest trees are infested for years with incipient Fungi, without any outward sign of their existence, till unexpectedly the pileus or fruit bursts forth, and the work of destruction is certain and speedy. It is the mycelium which constitutes what is called Mushroom spawn; and the fungous stones of Italy which, when watered, produce at pleasure a crop of edible Fungi. It is this again which in the entophyllous* Fungi traverses the cells (as represented in the accompanying sketch), waiting only fit proportions of heat and moisture to make their appearance, to the detriment of our harvest. I am not aware that the subject has at present been properly investigated, but there can be little doubt that the dark-coloured plants of corn, which may be pronounced beforehand as certain to be attacked in due time by their peculiar parasites, would, if examined as soon as this appearance is manifested, show evident indications of the lurking mycelium. At a later stage of growth, when the enemy is merely waiting for a happy moment in which to declare himself, the observation of the mycelium is easy enough.

Puccinia graminis (common mildew), with its mycelium penetrating the subjacent cells; from Corda.

I have not attempted to give any definition of the term Fungi. In bodies of such various forms and habits, it is almost impossible to give a faultless definition; and however easy it is to criticise, it is very difficult to improve. Indeed some Fungi and Lichens approach so near to each other, not only in outward appearance but in structure, that it is merely the practised eye which can determine accurately to which tribe certain individuals ought justly to be referred. In following up the subject I shall first dispose of those productions which, though classed with Fungi, have really no title to be so, but are mere diseases of the cellular tissue of the plants on which they are produced.—*M. J. B.*



* Growing inside of leaves.

THE ROSE-GARDEN.—No. XIX.

(*Continued from page* 620.)

Grafting.—Where buds have failed, or a good choice of scions be attainable in February, from plants which require pruning, let the produce of each tree be examined after cutting it in, which must in this instance be commenced two or three weeks before the usual time; a selection may then be made of those which are the finest, and their thickest ends (care being taken that the produce of each tree be tied in a separate bundle and ticketed) placed in a lump of moist clay an inch deep; the clay must then be pinched tight round them, and the whole placed in a potful of earth (above two-thirds of the shoot being left free) until ready for use. It must be remembered that at the end of each shoot there will probably be one or more buds open; these must be carefully cut off from the shoot, or they will infallibly exhaust the others.

The exact time for removing the scions from the parent tree, must depend upon the season. Some time during the first three weeks in February is the usual period. There does not exist an actual necessity for cutting the scions until they are required for use, but then it will be more difficult to select the number required in a state fit for use, and there is a greater chance of their going off, if the weather remain cold, or the buds not immediately supplied. Scions cut when the sap is quite down, carry better and are in every way more hardy; and such failures as may take place occur before they are used, the useless ones shrivelling whilst laid by, leaving those which are desirable to use fresh and vigorous.

Let the shoots remain for three weeks in an outhouse, or any other place, neither very dry nor very damp, where neither wind nor sun can come in contact with them; the clay being damped with a sparing hand, if the generality of the scions appear to shrink. During the first week in March the head of the stock (in which the sap should be beginning to rise), is to be cut off horizontally; a slit made in it, straight downwards, of a couple of inches, or an inch and a half long, without injuring the sides of the bark. The scion is to be taken in the left hand, three buds, or two if the stock be not large, being left upon it; the lower extremity must then be cut in the shape of a wedge, the back being rather the thinnest, and the lowest bud about half an inch above the thick end of the wedge. In doing which, care must be taken that the bark be undisturbed; and each scion so placed that when entered in the stock all the buds may point outwards, or, at any rate, be in such position that the shoots from them may not interfere with each other. The end of a budding-knife, or a little wooden or ivory wedge, may be used to open the slit in the stock on one side, and the scion, with the thickest part, or front outwards, must be placed in the other, care being taken that the edge of the inner bark or liber of the scion touches the edges of the inner bark of the stock, all the way down; the wedge may then be removed, another scion entered in its place, the slit being kept open by the first; if the size of the scion be only half the size of the stock, a shoulder may be left to the former, and the chances of success thereby increased. Any number of scions may be inserted in the same stock, but from one to four at most are all that are desirable in the present case, to cover completely the head of the stock, which is apt to receive much injury from the weather, if not carefully attended to. The object of laying by the scions, is that the stock may be the forwardest, and be enabled to supply the sap, and force them forward at once, instead of lingering while they perish from exposure and want of nourishment. But there is this advantage in claying and laying by scions; viz. the separation of the vigorous from those which are weakly, which latter will sometimes shrivel and go off long before they are wanted, leaving their neighbours sound and healthy; this declension, however, may frequently be ascribed to a deficiency of moisture, from the clay having been permitted to get too dry. When the shoots are on, the whole must be tied up with a bast ligature, to prevent the scions from shifting, which from their wedge-like shape they will have a tendency to do, when the rise of the sap swells the stock, thereby diminishing the juxtaposition of their respective libers, and the whole beneath the lowest bud covered with grafting clay, totally excluding air, sun, and rain. If the clay crack it must be renewed, not by shifting, but by filling up the crack. In about six months the clay may be removed, and the wound covered with mixture; this latter on no account must be omitted.

Home Correspondence.

Planting Pines in Tan.—One of the greatest misfortunes of almost all horticultural discussions is the want of the disputants being just to each other, as we are too frequently more desirous of obtaining a personal triumph, than of yielding to the triumph of truth. From Mr. Hamilton's reply to my remarks on the above subject, a stranger would suppose that I had passed unmitigated censure upon his whole work, whereas I have merely expressed my doubts, and doubts warranted by circumstances, as to the propriety of adopting one part of the practice which he inculcates. For venturing to do this, Mr. H. has thought proper to commiserate my [illegible] and to [illegible] he has used a small [illegible] with the tan. [illegible] making me say this which I never said or thought in it. Thus I am represented to have said "there parts of decomposed leaves" (I wish I had done so), "to one of tan," whereas I never mentioned the proportion in which they were used at all; and I may now state that not more than one-eighth of the mass consisted of leaves, and this indeed was only used for the fruiting plants, while the succession ones were planted in what Mr. H. is pleased to designate "pine tan." In truth, admitting the use of tan at all, so suitable did the material appear that I have not the least doubt if Mr. H. had passed by at the time we were using it, he would have said, "You could not make use of a finer article." However, in both cases the experiment is a failure; the fruiting plants were irreclaimable, and have been thrown away some time ago; the succession plants began to improve as the tan decayed, but they rooted so reluctantly into it that I determined to remove them, and they have been growing in soil for some weeks past. In taking them up, it was very evident that tan, at least such as I get near the Metropolis, is not suited for the growth of Pine plants. Very few of the roots had extended beyond a few inches from the ball of earth which adhered to the roots at the time of turning out the plants, and these roots had a stinted and very unhealthy appearance; but, strange to say, the ball of earth was a mass of fibres as fine as the roots of Heaths, and on examination I find these are now progressing freely into the fresh compost which surrounds them. Nothing could more satisfactorily demonstrate the inutility of tan as a medium for Pine plants to grow in than the great difference that was observable between the plants above adverted to and those growing in compost in the same pit. In the tan they were disgraceful, and I should have been ashamed to have shown them; only, being planted in a great measure for experiment, I was desirous of showing my friends that the experiment was a failure. Those planted in soil grew as luxuriantly as could be desired, the roots ramifying through the soil in every direction, and many of them were as thick as the pen with which I am writing. Now, judging from this experiment, Mr. Hamilton is surely mistaken in supposing that a small quantity of leaves mixed with tan would injure it. If Pines will grow in tan, which possesses no fertilising properties, as is proved by the analyses of Sprengel and other chemists, they will grow much better by an admixture of leaf-mould with the tan, which is known to contain most of the essential elements of vegetable organism; indeed, one of the most successful Pine-growers in the country, viz., Mr. Malleson, of Claremont, fruits all his plants in half-decomposed leaves, and few persons grow Queen Pines, as a general crop, in better style. We have also the evidence of Mr. Fleming, of Trentham, to the same effect. Mr. Rushton is surely mistaken in his notions regarding the fertility of tan: the very fact of his Fig having produced so great a mass of roots in it, proves that it was not rich in nutriment, or why did Nature provide so many mouths (roots), with which to feed the plant? All experience proves that when plants are growing in poor soil, they make a greater quantity of roots than when growing upon a dunghill; and hence the propriety of using sand in propagating, and of picking out plants intended for transplanting on light sandy soil. This is a law of nature, and therefore immutable. I doubt not but Mr. H. has been successful with the tan of his neighbourhood, but he must recollect that the curing of hides differs so much in different tan-yards, that what may be suitable for plant culture in one place, in another may be poisonous to them; and therefore, as we have no means of ascertaining the purity of tan, it will be better to abandon its use altogether, and use a proper compost, than run the risk of injuring plants by using an improper material. From Mr. H.'s letter, and also from the concluding sentence on Pine culture in his Treatise, we have strong presumptive evidence of his having some misgivings himself as to the propriety of using tan; for in the former he says, "The most of my fruiting plants are growing in a mixture chiefly composed of soil similar to that recommended in my Treatise, and such as I will always recommend where the tank system is used." At page 103 of his Treatise he says, "When a congenial bottom-heat can be communicated independently of fermenting materials, why not use a proper compost? And for this purpose I would recommend nothing but broken bricks and fresh sods, roughly chopped, of equal quantities, which will keep the bed in a porous state, and allow the atmosphere to have free access to every part of the compost. Although this plant will grow quicker in fresh tan than in compost, yet when the deficiency of bottom-heat is obviated by the improved system of communicating that agency, such as tanks, hot-water flues, &c., we may naturally expect the fruit to be larger than when grown in the latter compost." This quotation affords pretty conclusive evidence of Mr. H.'s misgivings as to the excellence of his favourite compost.—*Judex.*

Cabul Melons.—As many people may be led to suppose, from an advertisement by Mr. Cuthill, which has appeared in the *Chronicle* lately, that I lay claim to the merit of introducing or first growing the Cabul Melon, I beg to say, that the Cabul Melon grown here was raised from seeds that were given to me; that it is the same sort which is grown in many other places; that I have not distributed any seed; and that I never heard of such a Melon as "Fleming's Trentham Cabul Melon," until, in my [illegible] p. 649, I saw it advertised.—*C. Fleming, Trentham Gardens.*

Rare Orchids.—[illegible] the remarks of "Philologus" [illegible] Philologus, p. 642, led me to [illegible] that I still [illegible] that apparent irreconcilable. But if [illegible] of names is admitted to be

unavoidable, surely inaccuracy of colours—if inaccuracy it be—there is far greater excuse for. In relation to Mr. Paul's "Observations on the Cultivation of Roses in Pots," where, at p. 28, Niphetos is described as snowy white, and at p. 31 lemon; I find in the first instance it is described as a forced Rose, and as such it is actually white. If "Philalethes" looks to the work in question, p. 28, a few lines lower down, he will find this sentence: "The colours of Roses are much altered by forcing, coming much paler, especially if a great degree of heat be maintained." This to me accounts for the seeming incongruity; for Niphetos has a lemon appearance when blooming naturally. The omission of Lamarque in Mr. Rivers's list of 20 Noisettes, was more probably owing to its tenderness than an oversight. I consider that every allowance ought to be made in favour of Rose Catalogues, which are circulated gratis, and which, it must be admitted, are of great service to all lovers of Roses.—*Philo Justitia.*

Toads.—About four years ago I brought from Jersey a large toad, which I keep in a small frame. It is very fond of insects, and one day this summer one of my servants gave it about 50 of the small brown beetles which are to be found on the Yellow Briar. It rarely, if ever, strikes at an object with its tongue, unless it be moving, and seems to project its tongue about an inch or inch and a half. A few days since, seeing some wasps eating some fruit lying on the ground, I fetched the toad and placed him near them. He soon caught sight of them, and ate several, and they seemed not to have the power of stinging him. The largest insect I ever saw him eat was a cockchaffer. Toads seem particularly fond of woodlice, and I have induced a small English toad to eat a white butterfly: in this case it had to make use of its claws to push the wings into its mouth. I have noticed this small toad keep its mouth open for some time after having eaten some wasps, and almost thought that they had contrived to sting him, but he soon was able to eat another wasp, and afterwards appeared none the worse.—*T. O'Reilly.*

Strawberries, &c.—Mr. Bree says, (p. 621) "that a three-year-old Strawberry-bed will produce more fruit than a two-year-old bed. I have tried the experiment upon two beds: from the three-year-old bed I cut off all the leaves; but be it understood I did not destroy any of that year's runners, for I consider that they are of more value than the old stools, many of which, when raking off the leaves, I destroy, in order to give the runners a better chance. When the leaves were cleared away the bed was well manured; and from this bed I obtained as many Strawberries as I gathered from the one-year-old bed, from which I only cut off the runners, and which was, at the same time, also well manured. The reason I assign for having as much fruit from the four-year-old bed as from that which was only two years old, is my letting that year's runners remain. The beds were dressed late in the autumn. From experience I can say that the Strawberry cannot be cultivated with advantage more than three years on the same piece of ground; I have always found that the one and two-year-old beds produce by far the best Strawberries. This is not my opinion only, but it is also that of some of the best cultivators of this valuable fruit. With regard to the application of salt to Asparagus, the Editor says "to put it on after the haulm is cut, is to pickle, and not to manure." Surely Mr. Bree does not imagine that I remove the soil down to the crown of the roots in spring before I apply the salt. If so, he is mistaken; it is put on the surface of the beds, and without injury to the young shoot.—*Villegius.* [In order to put an end to the discussion about the age at which Strawberry-beds cease to be productive, it is as well to say at once that that depends entirely on the soil. We could point to beds of the Old Pine Strawberry in Hertfordshire, which, when 20 years old, bore as well as when 2 years old.]——*H. A. Wood, Statfold Hall,* says, "I quite agree with the statement made by Mr. Bree (page 621), viz., 'that cutting off the leaves of Strawberries is an unscientific system.' It deprives the plants of their respiratory organs. If science is correct, in the economy of Nature leaves have a peculiar function to perform, viz., elaboration of the sap. It is admitted that the embryo fruit-buds are formed at the expense of the elaborated sap; if so, should we not encourage as much as possible this beautiful process of Nature, and reasonably consider that the more elaborated sap there is, the better: the question then is, How is this to be obtained? Theory would answer, by retaining the foliage entire. If the leaves are mowed off after the fruit is gathered, a considerable portion of time elapses before the plants will have renewed their foliage; during this period I consider that the plants are losing time, which is most important, as many bright suns will have passed away before elaboration is again in active operation. The time lost may perchance sometimes be regained in the case of a dry and cloudless autumn; but in a wet and cloudy season, a very different result must be expected. On the other hand, by retaining the foliage entire, we embrace all the advantages that summer and autumn offer. Unless leaves were of important service, Nature would not have bestowed them; it is inconsistent to take them away, and at the same time presume to be assisting Nature in perfecting her works. Plants are composed of several distinct parts, each part having its own office to perform; these parts co-operate with each other, and form a compact whole. If we take away one of them the whole is broken, and disorganisation is the consequence; in fact, mowing off the leaves of Strawberries is against the general practice of gardening; for in the cultivation of either fruits or vegetables, we certainly find disconcerted if the foliage is in an unhealthy state. Witness the attack of insects if they are permitted to reign. What is the result? Death, or a severe injury ensues; and why? because the lungs are diseased, and this checks the system. How much greater, then, must the check be if we remove the lungs of the plants entirely! "J. H." very lately (page 638), after stating that he mowed the leaves off every other bed, says—'During this season there was no difference between the crop on the beds that had not been touched, and that on those which had had the leaves mowed off.' This plainly shows that with a favourable season such as last autumn was, there was no advantage gained by mowing off the leaves; and, I attribute their being equal to those beds that were not touched, entirely to the favourableness of the season. Having thus a chance to make up for lost time, I may add that there are great odds against mowing off leaves: my practice is not to cut them off."

Strawberries.—From having followed the plan of never cutting the leaves from the Strawberry plants, and only slightly forking the beds, without injury to the roots of the plants, and giving a good coating of compost manure to the beds, before the winter sets in with its severity, my beds at this moment exhibit luxuriant blossoms, and supply my table with three or four different kinds of Strawberries, and may do so for another fortnight, provided this fine warm autumnal weather should last so long.—*B. D. Greys.*

Packing Seeds for India.—As inquiries are occasionally made respecting the best mode of packing and sending seeds to India, perhaps the following statement may be of use in showing with how little care seeds may be transported from one country to the other, without injury to their vegetative powers, provided they be previously in a fit condition, *i. e.* in a ripened and well dried state before despatching them:—Leaving India unexpectedly in the spring of 1840, I happened to have some seeds, which had been gathered chiefly in the month of November of the preceding year, without the remotest thought or intention of sending them to England, and they were put up in paper packets inclosed in a paper wrapper, and kept in a common travelling box with other articles of personal use. As I came home by the overland route, some things not convenient for carriage were left to be forwarded by a sailing vessel, and amongst them the box with the seeds in it. The boxes, I suppose, were placed in the hold of the vessel with the rest of the cargo. The ship arrived in England in November, but I did not get them till February 1841. Most of the seeds were given away; but having a small portion of some of them left, I sowed three kinds in pots both last year and this, giving them no further artificial aid than the protection of glass, with a southern exposure. Those of last year vegetated and grew freely; this year one sort germinated and just came to the surface and died off; the other two have grown freely. Thus notwithstanding it is now approaching five years since these seeds were gathered, and no particular care has been taken of them at any time, being kept in the paper packets they were originally put into, and the box that contained them must have been six months in the close hold of a ship, they have hitherto retained their vegetative powers little impaired. I attribute this partly to their being perfectly ripened, which indeed they could scarcely have failed of being, in the driest season of the Indian climate; but also and more particularly to their being well dried by the slow and sustained action of a very dry atmosphere during the six months they were in India, *i. e.* from November to May, the driest portion of the year. Hence I deduce as a practical corollary, that if seeds intended for India were kept for some time after ripening in a stove-heated room, the atmosphere of which must necessarily be in an arid state, it would be of little consequence how they are packed and sent to India.—*J. H. H.*

Salt for Fruit-trees.—I have, on a lawn, a large handsome Bigarreau Cherry-tree, which blossomed and fruited, and then dropped. I cut from the turf a triangular six-inch trench round it, 6 feet from its trunk, half filled it with salt, and put the turf on again. I have had noble crops ever since (seven years), but it makes little or no wood.—*Anon.*

Destruction of Small Birds.—I have observed from time to time in the *Chronicle*, remarks on the relative merits and demerits of those generally-despised birds—house-sparrows. I would mention that in some parts of the country it is still usual to set a price upon their heads; which, of course, has the effect of diminishing their numbers very considerably. This, it is said, is politic; and in the winter season it may be so; though to me it appears unnecessarily cruel. When, however, this onslaught is carried on in the spring, and still later in the season, I can tell Messieurs the farmers, and market-gardeners, that they are doing themselves a serious injury, for the quantity of insects and small vermin that these birds consume is positively incalculable. They are to the farmer in the fields, and to the gardener in the orchards, precisely what the scavangers are to the streets of London in sloppy weather. It becomes, therefore, a consideration of £ *s. d.* as to their preservation or destruction. My own observation, though I am no farmer, is in favour of the farmer; for I confess myself a debtor to the numerous sparrows domesticated in my neighbourhood for many essential services rendered. During the spring they cleared my Gooseberry and Currant-trees most effectively from caterpillars and the green-fly, and I also watched narrowly their active operations on the Rose and other trees of the garden, whose insects they swallowed in multitudes. Some will doubtless smile, when I tell them further, that sparrows are, when properly taught, admirable song-birds! Taken when callow (this is indispensable), from the nest, and brought up under a canary in fine voice, they have been known not only to equal, but even to surpass their masters in brilliancy of execution. I am well versed in these matters, having made them the subject of deep study for many years. In conclusion I would add, that I number the sparrows among my good friends.—*William Kidd, New Road, Hammersmith.*——It is not difficult for individuals to decide upon which species of bird or animal they may wish to be extirpated; this, however, cannot be taken as a rule to guide others, either in the protection or destruction of the feathered tribe. As an amateur gardener, I must confess I am rather inclined to the Waterton doctrine of allowing all birds to exist undisturbed; but I have no doubt my neighbour, the market-gardener, differs in opinion with me, and justly so, he having to gain his livelihood by his exertions. I have to preserve my health and gratify my senses by the same occupation. I would willingly give the best half of the fruit of my garden to our songsters, in return for their cheerful notes, and I would not even deny a small share to the impudent sparrow, considering the number of insects and grubs he exterminates during the year. Yet I can scarcely expect the poor man to do the same, when the produce of his patch of ground has to be converted into bread. The result of my labour is luxury—his necessary food. The mischief occasioned by hard-billed birds, viz. sparrows, finches, &c. &c., is great where they are permitted to increase without interference; and, on the other hand, their extinction would be attended with serious consequences. We kill every description of hawk which comes within our reach; we must therefore take upon ourselves their natural occupation, and endeavour to keep the smaller fry in order, by limiting their numbers without sweeping them from the face of the earth. The middle course is recommended—so difficult to practise, prejudice rising up on one side, and enthusiasm on the other. When the Wheat is ripe, a foray made by a large flock of sparrows is a serious matter to the farmer, and a person who has not witnessed their voracity would not credit the quantity they can in a short time swallow, leaving many hundreds of stalks without a grain in their heads. Although it is an incontrovertible fact that, in masses, sparrows, &c. are decided enemies, yet, in smaller bands they are useful allies. The soft-billed birds, those living principally on insects (sometimes plundering a little fruit), and visiting our gardens in spring and autumn, are birds of passage, coming to this country for the breeding season, and leaving us again as the winter approaches. These little strangers should be left to the chances of travel, which will sufficiently thin their ranks without the assistance of powder and shot; and even were they more numerous than they are, I look upon them as indefatigable labourers in the vineyard, well earning fifty-fold more than they eat. I believe the fruit is often knocked off when in search of the maggot, and not for the purpose of being devoured. Under the above class come fly-catchers, warblers, &c. &c. I have left the rook till the last. He is in the field what the sparrow, &c., are in the garden—an admirable aid in agriculture, but a sly rascal, and requiring to be well looked after, and not permitted to have exactly his own opinion on the subject of the increase of his family, manner of feeding, &c. Do not exclude him from a moderate share of the good things, in lieu of work done; but, as in the case of the sparrow, he must be under control. The rook's appetite is most accommodating, and not easily satisfied as to quantity; nothing comes amiss to him when hungry, and he cannot be said to be exempt from the charge of wanton mischief. However, under all circumstances, *Corvus Frugilegus* is a good fellow when under discipline, but leave him to his own inventions, and he is a sad scamp, having no sort of regard for private property.—*Falcon.*——*An Old Subscriber* writes, "I do not think that those who object to shooting birds can have been so much annoyed as I have been. My Strawberries, Peas, Cherries, Currants, Gooseberries, Peaches, and now Grapes, have been this year most voraciously attacked by them, and nets have no terrors for them. They are now, by some means I cannot account for, devouring a late crop of Peas most carefully netted. I was once a friend to birds, but now I do not know what to say."

Canaries.—I have some valuable Canary birds, 30 or 40 in number, but I am so troubled with mice, that I fear I must resort to that old-fashioned remedy for such pests—a cat. I fear puss might catch birds as well as mice, and should be obliged if any of your correspondents could devise any other means for ridding my house of such rapacious vermin.—*Nemo.*

Salt for Asparagus.—I have found the greatest advantage from using this for Asparagus, applied in November. My beds, which were worn out, are rapidly improving. I adopted the old-fashioned custom last year of sowing seeds in the old bed, when I sowed on the salt: the plants came up vigorously. I have dressed once with salt this summer, and I propose using no more this year; but I intend to apply good rotten vegetable manure instead.—*An Old Subscriber.*

Morphology.—It may not have occurred either to those who have propagated Gloxinias, Achimenes, or indeed any Gesneraceous plant, by means of its leaves, or to those who may have witnessed this mode of propagation, that it is a powerful argument in support of Morphology; and not being limited to Gesneraceæ, but admitting of very extensive application, its force as an argument becomes proportionably increased, in consequence of its being the farther removed from what might seem to be an exception to the general rule. It may be remarked, too, that several of the Achimenes, and A.

pedunculata especially, should be regarded as plants of very suspicious character by the opponents of this doctrine; for in several cases during the past season it has been observed that this A. pedunculata has produced scarcely any flowers, but in their usual position abundance of little scaly bulbils have been protruded; here, what should have been flowers, have been developed as bulbs. As far as I have observed, this has been the case to a much greater extent with plants which have been exposed to a considerable degree of cold—such as being placed in an open airy greenhouse—than with such as have been kept in a stove, where the air has been duly warmed; and also has been more apparent in the case of plants that have been grown in considerable and compact masses of soil, than with such as have been supplied with a more open medium, according better with the natural habit of the plant. The conclusion which may be drawn from this circumstance seems to be, that in consequence of the roots being placed in soil of an unsuitable kind, and in circumstances unfavourable to the proper and regular development of the several parts of the plants, the latter become induced to make a strong effort for their perpetuation, which might seem to be endangered; and, under these circumstances, myriads of latent germs are put forth instead of the more fully organised particles, which would have been formed had the flowers been produced, and enabled to perform their natural functions; and we may further conclude, that this result is favoured by the want of proper temperature as the plants approach maturity. To return to the question involved in the propagation of plants by means of their leaves: if we take a Gloxinia as an example, when in its perfect state of development, we shall find it furnished with root, stem, leaves, and the floral apparatus, each bearing their respective characters, and performing their allotted functions of nutrition and reproduction. Now, it cannot be denied that if these parts are maintained in their reciprocal relation to each other, the leaves would provide, or rather prepare, the proper nourishment for the flowers, and these in their turn would assist in bringing forward the seeds imbued with the principle of life, and capable by its exercise of perpetuating their race; when this process was completed, the leaves would naturally decay, but if this course of nature is interrupted—if the leaves are removed without having expended their powers in the discharge of their natural functions, and are then placed under suitable and congenial circumstances, each of them may be converted into several separate and distinct seats of life; that is to say, several young plants can be produced from each leaf, and these young plants will, in due time, become furnished with all the parts necessary to render them perfect (root, stem, leaves, and floral apparatus), and thus will be enabled to perpetuate, by seeds, the race from which they sprung. If it could reasonably be assumed, and were even admitted, that in the Acorn an Oak tree may be detected, with all its parts present, though in miniature!! (which, by the way, is not the case,) would it be possible, even with a proportionately increased magnifying power, to detect the various organs which this leaf-propagation brings into existence? These must be present within the tissue of the leaf in their ultimate character, if Morphology be not true. And if it be not possible to detect them (and most certainly it is not), then we are forced to the conclusion that the living organisable tissue of the plant is acted on by the circumstances and conditions in which the plant is placed, and consequently, that all the appendages of the vegetable axis being developed from this tissue, under the influence of these circumstances and conditions, are of one common origin; therefore, I repeat that in the vegetable kingdom the nature of the development becomes changed, according to the circumstances under which the parts are developed.—*T. Moore.*

Pine-apples.—In reply to an "Admirer of well-grown Pines," I beg to state that the plants which produced the large fruit at Gunnersbury Park were planted in the fruiting pit in July, 1842; they were then about six months old. With respect to manure, two good one-horse cart-loads of fresh horse-dung is sufficient to make a lining all round the pit. The manure of two horses regularly applied would, I have no doubt, keep up sufficient heat in the pit to bring the fruit to perfection: the lining was all turned over once in 14 days, one half being turned every seven days. From the appearance of the fruit I should suppose it was good in quality.—*G. Mills.*

COUNTRY SHOWS.

Bedhampton Cottage Gardeners' Show, Sept. 26.—This was the third and last Exhibition for the season. The prize flowers—the Dahlia and China Asters—together with the bouquets of various flowers, did great credit to the parties, one in particular, had been but twelve months in possession of his allotment, and succeeded in producing, both in variety and quality, a display that showed most favourably his exertion and good taste. The vegetables were admirable; some of the Onions exceeded 14 inches in circumference. The winner for the best basket of Vegetables had Cabbages, Carrots, Parsnips, Onions, Potatoes, Lettuces, Radishes, two sorts of Beans, Cucumbers, Pumpkins, Spinach, Turnips, Peas, Brussels Sprouts, Celery, and Endive, all from a few rods of ground, in such condition that they might have been envied by the owner of many a large garden, with all his appliances and means to boot. There was an excellent feeling evinced among all parties—many a good-humoured challenge, one against the other, as to their mutual position the next time they meet in opposition; and all that came in his second were fully resolved that it should not be for want of exertion if they did not carry off the prize next season. From circumstances that transpired, it might have been seen that the allotment system might be considered the poor man's landowner—by which, with sobriety and pains-taking, he might fairly hope to win a solid, manly, independent position, which is of an interest to the land around him; a self-respect and a calm patience that cannot be bought by him through any other channels; indeed, many a wasted hour might thus be made to add thousands to the family stock. The same philanthropic feeling, managing this institution, would, no doubt, lend that kind assistance to arrange [illegible] character, which might, by the means of [illegible] to the produce from the allotments; the advantage [illegible] would be but small; the emulation being so [illegible], would be the more enjoyed and the more stimulating, and [illegible] in producing in the end results of the most satisfactory character.

Royal Horticultural Society of Cornwall.—This was the 41st Exhibition, and the last for the present year. The display of flowers, plants, and fruit was good, and there were also many choice and well-grown specimens. The fruit was remarkably fine, and particularly the Pines, Grapes, and Melons. The following prizes were awarded:—Grapes: Best single: 1, J. Vivian, Esq.; 2, Queen, Earl of Falmouth. Heaviest do.: Black Jamaica, 3 lbs. 5 ozs., J. Vivian, Esq. Melon: King's Own Greenfleah, 1, W. Daubuz, Esq.; 2, King's Own Greenfleah, Mrs. Bull. Grapes: White Muscat of Alexandria, 1, Earl of Falmouth; 2, Red Hamburgh, Sir C. Lemon, Bart., M.P. Best dish of do., of named sorts: Black Frontignan, White Frontignan, Muscat of Alexandria, Black Hamburgh, Victoria, Black Prince, 1, J. P. Magor, Esq.; 2, White Muscat of Alexandria, Black Constantia, White Frontignan, Black Prince, Grizly Frontiguan, Black Hamburgh, Earl of Falmouth. Peaches: Noblesse, 1, J. Vivian, Esq; 2, Red Magdalen, A. Fox, Esq.. Best dish of do., of sorts: Chancellor, Red Magdalen, Grimwood's Royal George, Violet Hâtive, Admirable, Noblesse, Royal Kensington, Old Royal George, 1, J. P. Magor, Esq.; 2, Admirable, Royal Kensington, Violet Hâtive, Smith's Newington, Ford's Seedling, Noblesse, Royal George, J. Vivian, Esq. Nectarines: Elruge, 1, Rev. C. Rogers; 2, Elruge, Sir J. C. Rashleigh, Bart. Best dish of do., of sorts: Veitch's Seedling, Bowden's Seedling, Elruge, Peterborough White, Scarlet, J. P. Magor, Esq. Pears: Duchesse d'Angoulême, 1, Capt. Reynolds, C.B.; 2, Summer Bon Chrétien, A. Fox, Esq. Apples: Kerry Pippin, 1, Rev. C. Rogers; 2, Ribstone Pippin, Rev. T. Philpotts. Cherries: Morello, W. Daubuz, Esq. Plums: Coe's Golden Drop, 1, Sir C. Lemon, Bart., M.P.; 2, Coe's Golden Drop, G. C. Fox, Esq. Extra.—Cherries: Morello, Sir C. Lemon, Bt., M.P. Currants: White Dutch, J. S. Enys, Esq. Flowers.—Collection of Ornamental Plants: Æschynanthus grandiflora, Achimenes longiflora, A. grandiflora, Passiflora kermesina, Clerodendron paniculatum, Stephanotus floribundus, Vinca rosea, V. alba, Manettia glabra, and two Balsams, Rev. T. Philpotts. Ornamental Plant, in flower: Veronica astenoides, G. N. Simmons, Esq. Best named collection of Stove Plants, in flower: 1, Achimenes longiflora, Rondeletia speciosa, Gesnera zebrina, Ardisia crenulata, Ixora crocata, I. bandhuca, J. P. Magor, Esq.; 2, Gloxinia maxima, G. rubra, Achimenes rosea, A. longiflora, A. grandiflora, Browallia alata, B. alba, Thunbergia alata, T. aurantiaca, Lantana mutabilis, L. crocea, Ipomœa quamoclit, Mammillaria pulchra, G. N. Simmons, Esq. Single specimen of ditto: Lisianthus Russellianus, F. Passingham, Esq. Collection of Orchidaceous Plants: 1, Stanhopea oculata, Acropera Loddigesii, Oncidium Papilio, Epidendrum cuspidatum, Oncidium flexuosum, Epidendrum cochleatum, Cattleya Loddigesii, C. Forbesii, Gongora maculata, J. P. Magor, Esq.; 2, Cattleya Harrisoniæ, Epidendrum ciliatum, Zygopetalum Mackai, Catasetum luridum, C. tridentatum, Epidendrum cochleatum, Oncidium leucochilum, G. C. Fox, Esq. Specimen of ditto: 1, Stanhopea oculata, J. P. Magor, Esq.; 2, Cymbidium aloefolium, Sir C. Lemon, Bart., M.P. Fuchsias: Silver Medal, 1, Harrison's Goldfinch, Grovehill, Epps's Duke of Wellington, Harrison's Pearl, Defiance, Curmeckii, G. N. Simmons, Esq.; 2, Eppsii, Rogersiana, Grovebilli, Smith's Alata, Frostii, Smith's Majestica, F. Passingham, Esq.; 3, Robusta, Majestica, Champion, Venus Victrix, Magnifica, W. Hockin, Esq. Dahlias, dissimilar blooms: 1, Mrs. Shelley, Paul Pry, Admiral Stopford, Great Mogul, Mrs. J. Richardson, Swindon Rival, Lee's Bloomsbury, Antagonist, Prince of Wales, Standard of Perfection, Essex Triumph, Aurantia, Twyford Perfection, Beauty of Surprise, [illegible] Princess Royal, President of the West, Hero of Stonehenge, Mr. R. Dunn; 2, Essex Triumph, Bridesmaid, Indispensable, Rouge et Noir, Perpetual Grand, Westbury Rival, Sir Robert Sale, [illegible] Perfection, Egyptian Prince, Marquess of Lansdowne, Lady Cooper, Twyford's Perfection, Bedford Surprise, Prince Albert, Wheeler's Maria, Antagonist, Competitor, Princess Royal, G. C. Fox, Esq. Best 12 ditto: 1, Phenomenon, Swindon Rival, Essex Triumph, Dodd's Prince of Wales, Admiral Stopford, Mrs. Shelley, Great Mogul, Satirist, Antagonist, Standard of Perfection, Lady Antrobus, Dodd's Orange Superb, Mr. R. Dunn; 2, Prince Albert, Bedford Surprise, Sir Robert Sale, Yellow Perfection. Competitor, Princess Royal, Twyford's Perfection, Westbury Rival, Perpetual Grand, Essex Triumph, G. C. Fox, Esq.; 3, Beauty of the Plain, Pickwick, Lady Cooper, Bridesmaid, Standard of Perfection, Beauty of Sussex, Highgate Rival, Princess Royal, Widnall's Eclipse, Rouge et Noir, Virgin Queen, Andrew Hofer, Rev. C. Rogers; 4, Dodd's Prince of Wales, Essex Triumph, Princess Royal, Mrs. Shelley, Rouge et Noir, Lady Cooper, Prince Albert, Northern Beauty, Lee's Bloomsbury, Antagonist, J. S. Enys, Esq. Best 6 striped or tipped ditto: 1, Princess Royal, Queen of the Isles, Oakley's Surprise, Rainbow, Bridesmaid, Lady St. Maur, W. Daubuz, Esq.; 2, Princess Royal, Painted Lady, Glory of Plymouth, Purpurea alba, Northern Beauty, Charles 12th, J. S. Enys, Esq. Roses, Cut Flowers: Anna Maria, Yellow China, Indica, Carnescens, Jeanne Desprez, Devoniensis, R. W. Fox, Esq.; 2, Phœnix, Clara Sylvain, Aubernon, Smith's Yellow, Fulgoric, N. C. Stephens, Esq. Verbenas: Prince of Wales, Duke of Cornwall, the Bride, Tweediana grandiflora, Hendersonii, Hisloponna, Ponteyi, Ingramii, Odoratissima, and three Seedlings, G. N. Simmons, Esq. Florists', Nurserymen, and Market Gardeners' Prizes.—Dahlias: dissimilar blooms, 1, Hero of Stonehenge, Claudine, Twickenham Rival, Beauty of Sussex, Perpetual Grand, Indispensable White, Sir J. Richardson, King of Sarum, Thompson's Vivid, Mrs. Shelley, Queen, Aurantia, Dodd's Favourite, Rainbow, Proctor's Nonpareil, Mrs. Shelley, Rembrandt, Emma Noke, Madalene, Essex Triumph, Standard of Perfection, Lady Antrobus, Orange Superb, Bedford Surprise, Silver Medal, Messrs. Veitch and Son; 2, Egyptian Prince, Princess Royal, Perpetual Grand, Sir J. H. Richardson's Union, Admiral Stopford, Antagonist, Euclid, Orange Superb, President of the West, Rouge et Noir, Indispensable, Standard of Perfection, Queen of Trumps, Bedford Surprise, Argo, Hero of Stonehenge, Pickwick, Lady Cooper, Virgil, Essex Triumph, Burnbank's Emma Noke, Nonpareil, Mr. Pontey. Best collection of Plants: Veronica speciosa, Brugmansia parviflora, Boronia viminea, Cyrtoceras reflexa, Hydrangea japonica, Pentas carnea, Babingtonia camphorosma, Columnea grandiflora, Mr. Pontey.—*From the West Briton.*

Morningside Practical Gardeners' Society, Sept. 10.—This was the Autumn Meeting, at which the following prizes were awarded:—Dahlias: Mr. J. Dowrie, gr. to General Robertson, for Prince of Wales, Marquis of Lansdowne, Rouge et Noir, Prince Albert, Sir R. Sale, Essex Triumph, Perpetual Grand, Mrs. Shelley, Highgate Rival, Beauty of Sussex, Bishop of Winchester, and Princess Royal. Bellphenia: Mr. Downie, for fourteen blooms. Petunia: Mr. Downie, for purples, crimsons, Richardsonii, striatiflora, and Brown's No. 40. Marigolds: Prince and Albion, Mr. J. Young, gr. to T. Oliver, Esq. Dwarf Antirrhi: Mr. R. Scott, gr., Salisbury Green, for Pilot, Dreadnought, Pluto, Victor, Carnegie's Dreadnought, Victoria variegata, Rose-spotted Shrimpton, and Gladiola elegans. Pansies: [illegible] Mr. Downie, for [illegible] Gentleman's and Gentlemanly [illegible] Mr. Downie, for Rose Superior and Rival. [illegible] Mr. Downie, for Gladiolus, and Mr. A. Addie, gr. to Dr. Balfour, for Gladiolus communis. Asters: Mr. A. Addie, for Victoria, Victoria Superba, Victoria Rosea, Victoria Alba, Victoria Striata, Victoria Purpurea, Victoria Lilacina, Victoria Coccinea, Victoria Carnea, and Victoria Variegata. Stocks: Mr. Downie, for Brompton, Ten-week, and Intermediate. Balsams: Mr. Downie, for Camellia, Rose, and Double White. Cockscombs: Mr. Downie, for Crimson and Yellow. Globe Amaranths: Mr. Downie, for Purple and White. Zinnias: Mr. Downie, for Elegans and Pumila. Collection of Annuals: Mr. Downie, for Rose Queen, Lady Crewe, Mr. Hardy, Princess Royal, Mr. Hardy, Princess Dowager, Mr. Hardy, Mr. Nunneley, Dahlonian Beauty, Rose Queen, Duchess of Newcastle, Mr. Gaddy, White Rose, White Flag, Mr. Hardy, Yellow Ball: Miss d'Urban, Mr. Nunneley. Rose Plants: 1, Queen Adelaide, Mr. J. Dowrie, gr. to Basilius Sexegenus, Mr. Dobson, gr. to J. W. Patten, Esq., M.P.; 2, Paphiopedilum spherosum, W. Hall, Esq.; 3, Cuvelia Mr. Dobson. Greenhouse Plants: 1, Epacris grandiflora, Miss P. Sharpe; 2, Calceolaria, Regent Standard, Mr. R. Gaddy; 3, Fuchsia Venus Victrix, Mr. J. Kendrick; 4, Tropæolum pentaphyllum, Mr. J. Dowrie, gr. to J. W. Patten, Esq., M.P.; 5, Tropæolum speciosum, W. Hall, Esq.; 6

Chancellor, Lady Constable, Mr. R. Sweet; Mont Blanc, Mr. J Clare.—*Autumn Medley, September 19.*—DAHLIAS—Fancies, Standard of Perfection, Mr. Hardy. *Dark or Maroon*: 1, Essex Triumph, Mr. J. Wright; 2, Admiral Stopford, Mr. Hardy; 3, Rouge et Noir, Mr. J. Wright. *Purple*: 1, Standard of Perfection, Mr. Hardy; 2, Pickwick, Mr. J. Wright; 3, Metella, Rev. T. Hinde. *Crimson*: 1, President of the West, Mr. Hardy; 2, Coronation, Mr. Hardy; 3, Indispensable, W. Hall, Esq. *Scarlet*:—1, Bloomsbury, Mr. J. Wright; 2, Dancroft Rival, Rev. T. Hinde; 3, Vivid, Mr. J. Wright. *Rose*: 1, Maria, Mr. Hardy; 2, Hope, Mr. J. Eaton. *Lilac*: 1, Mrs. Shelley; 2, Lady Harland; and 3, Widnall's Queen, Mr. J Wright. *White*: 1, Lewisham Rival, W. Hall, Esq.; 2, The Bride, Mr. Hardy. *Yellow*: 1, Parkmount Rival; and 2, Prince of Wales, Mr. J. Wright; 3, Cox's Defiance, Rev. T. Hinde. *Orange, Buff, or Bronze*: 1, Prince Albert, Mr. J. Wright; 2, Duchess of Richmond, Mr. Hardy; 3, Nicholas Nickleby, Mr. J. Wright. *White tipped, &c.*: 1, Lady Antrobus; 2, Phenomenon, Mr. Hardy. *Yellow or Buff tipped, &c.*: 1, Princess Royal; and 2, Unique, Mr. Hardy. *Seedlings*: 1, White tipped purple; 2, Red; and 3, Maroon, Mr. Hardy. *Pansies*: 1, Dr. J. Kendrick for Wilhelmina, Dowager Queen, Mulberry, General Reta, Peter Dick, Adelaide, Maria, Lady Douglas, and two seedlings. *Stove Plants*: 1, Cactus Ackermanni, Dr. J. Kendrick; 2, Achimenes coccinea, Mr. Bloore; 3, Lantana mutabilis, Mr. Bloore; 4, Gongora atropurpurea, Mr. Dobson. *Greenhouse Plants*: 1, Petunia triumphans, Dr. J. Kendrick; 2, Tmesipteris alata, Mr. J Clare; 3, Fuchsia exoniensis, Mr. Bloore. *Herbaceous Plants*: 1, Gladiolus psittacinus, W. Hall, Esq.; 2, Pentstemon coccineum, Mr. Dobson; 3, Lupinus Cruickshanksii, Mr. Penketh; 4, Cyclamen europæum, Mr. J. Clare. FRUIT AND VEGETABLES.—*Best Vine in a Pot*: Black Hamburgh, Mr. Dobson. *Pine Apple*: Montserrat, W. Hall, Esq. *Grapes*: Black Hamburgh, Mr. Hall. *Melons*: Peach, Mr. Dobson. *Plums*: Magnum Bonum, W. Hall, Esq. *Cherries*: Morello, Mr. Bloore. *Celery*: Seymour's White, W. Hall, Esq. AMATEURS.—*Apples*: Alexander, Mrs. Clare, *Pears*: Scimitar, Mr. P. Davies. *Onions*: White Port, Mr. Hardy. *Red Cabbage*: Mr. J. Eaton. *Celery*: Lancashire solid Red, Mr. J. Eaton. *French Beans*: Mr. Davies. COTTAGERS' PRIZES.—Fuchsia multiflora and Senecio elegans, Mr. R. Brett. EXTRA PRIZES.—*Grapes*: Black Hamburgh, Mr. Dobson. *Red Cabbage*: Mrs. Wagstaffe. *Pine Apple*: Enville, Mr. Hunt. *Plums*: Magnum Bonum, Mr. Clare, jun. *Apples*: Hawthornden, Miss Burdett.

Wingham Horticultural and Floral Society, Sept. 19.—This was the autumnal Exhibition. There was, as usual, a good display of fruits and flowers. The following is the award of Prizes:—PLANTS IN POTS.—*Fuchsias*: Exoniensis, Conspicua, Aurantia, Mr. Sankey. *Pelargoniums*: Punctata, Lady Peel, Seedling, Mr. Sankey. *Climbing Plant*: Passiflora quadrangularis, D. Denne, Esq. *Best Rose*: Madame Sevigné, J. Godfrey, Esq. *Greenhouse Plants*: 1, Pentas carnea, Lantana acuminata, Angelonia salicariæfolia, Marchioness Conyngham; 2, Cotyledon ovata, Rochea falcata, Echeveria coccinea, Mr. Sankey. *Best one*: Cassia corymbosa, Mr. Sankey. *Stove Plant*: Achimenes coccinea, Marchioness Conyngham. *Dahlias*: 1, Eclipse, Northern Beauty, Admiral Stopford, Mrs. Shelley, Prince of Wales, Essex Triumph, Lady Cooper, Sir R. Chester, Pickwick, Queen, Vivid, Antagonist, the Rev. J. G. Hodgson; 2, Defiance, Andrew Hofer, Lee's Bloomsbury, Queen, Pickwick, Argo, Suffolk Hero, Grace Darling, Exquisite, Springfield Rival, Bridesmaid, Seedling, Mr. G. Denne; 3, Mrs Shelley, Phenomenon, Lee's Bloomsbury, Hope, Prince of Wales, Le Grand Baudin, Princess Royal, Antagonist, Andrew Hofer, Virgin Queen, Essex Triumph, Springfield Rival, Mr. Sankey. *Best six*: 1, Asmodeus, Queen, Blue Bonnet, Eclipse, Admiral Stopford, Northern Beauty, the Rev. J. G. Hodgson; 2, Vivid, Mrs. Shelley, King of Lilacs, Essex Triumph, Bedford Surprise, Competitor, the Rev. C. Bayley; 3, Andrew Hofer, Bridesmaid, Queen, Pickwick, Maria, Exquisite, Mr. G. Denne. *Verbenas*: 1, Tweediana, Princess Royal, Rosea alba, Bridesmaid, Prince of Wales, Ruby, Hendersonii, Queen, Stewartii, Mr. Bladden; 2, Rosea alba, Tweediana, Stewartii, Princess Royal, Duke of Cornwall, Tweediana picta, Queen, Eximia, Melindres, Mr. Bladden. *Annuals*: Lupinus mutabilis, L. elegans, Erysimum angustifolium, Collinsia bicolor, Malva zebrina, Phlox Drummondii, Zinnia elegans coccinea, French Marigold, Spanish pink, the Rev. C. Bayley. *Hardy Perennials*: Lobelia fulgens, Pentstemon gentianoides, P. coccineum, P. pulchellum, Phyteuma campanuloides, Aster puniceus, Rudbeckia fulgida, Antirrhinum grandiflorum, Dracocephalum speciosum, Linaria dalmatica, Phlox omniflora, Coreopsis lanceolata, Lupinus rivularis, the Rev. C. Bayley. *Roses*: Eliza Sauvage, Nerine, Louis Bonaparte, Yellow China, Crimson China, Aglaiæ, J. Godfrey, Esq. FRUIT.—*Melon*: 1, Fletcher's Greenflesh, D. Denne, Esq.; 2, Egyptian Greenflesh, Lady Montresor. *Grapes*: Black Hamburgh, J. M. Hilton, Esq.; Muscat of Alexandria, Sir B. W. Bridges, Bart.; Black Hamburgh, J. Godfrey, Esq.; Frontignan, D. Denne, Esq. *Best collection*: Black Hamburgh, White Frontignan, Sweetwater, Claret, Muscadine, Black Frontignan, White Nice, J. Godfrey, Esq. *Figs*: Purple Ischia, the Rev. C. R. Hallet. *Peaches*: 1, Red Chancellor, Mr. Cozens; 2, Early Admirable, Mr. J. Elgar. *Nectarines*: Elruge, Mr. Cozens. *Plums*, grown against a wall: 1, Golden Drop, Mr. Cozens; 2, ditto, Sir B. W. Bridges, Bart. *Plums*, not grown against a wall: 1, Golden Drop, Marchioness Conyngham; 2, White Imperatrice, D. Denne, Esq. *Cherries*: Morello, Marchioness Conyngham. *Pears*, grown against a wall: 1, Jargonelle, S. M. Hilton, Esq.; 2, ditto, Sir B. W. Bridges, Bart. *Pears*, not grown against a wall: 1, William's Bon Chrétien, Mr. Bladden; 2, ditto, Mr. Dadds. *Apples*: 1, Kerry Pippin, Mr. Elgar; 2, ditto, Mr. Sankey. *Kitchen Apples*: Fair Maid of Wishford, Mr. J. Elgar. VEGETABLES.—*Peas*: Knight's Marrow, Mr. Cart. *Celery*: Solid Red, Mr. D. Deverson. *Carrots*: Altringham, Marchioness Conyngham. *Broccoli*: Cape, Mr. Elgar. *Kidney Potatoes*: 1, White Holland, D. Denne, Esq.; 2, Ramshorn, Mr. D. Deverson. *Cucumbers* Roman Emperor, Mr. G. Denne.

Reviews.

Suggestions towards an Inquiry into the present Condition of the Labouring Population of Suffolk. By the Rev. J. S. Henslow, M.A., Rector of Hitcham.

We beg—nay, we entreat the attention of all who are interested in the welfare of the poor—to this pamphlet, written by one of the most zealous and sober-minded men among the English clergy, and who is thoroughly acquainted with the *facts* relating to the rural population. It is more especially to Londoners that its contents are important, so that they may not be misled by a part of the London newspaper press, of great authority with them—and justly so when the subjects treated of are understood. Cockney reporters are not the persons to come to a correct judgment relating to country matters; and still less are they likely to do so when they quit the metropolis with only one eye open, and that with a twist in it. The cause of the incendiary fires, and soulless condition of the Suffolk peasantry, are traced by Prof. Henslow to their true source—want of employment at the wages, and to that only! In which we wholly agree with him. Many that must submit to competition unless the Suffolk farmers, without capital or energy, can succeed better than anybody. In the meanwhile, till they strike their statements, which may be expected about the Greek Calends, Mr. Henslow's excellent pamphlet may be taken as a true exposition of the case.

NOTICES of NEW PLANTS WHICH are EITHER USEFUL OR ORNAMENTAL.

LAGENIA* BICOLOR. Two-coloured Lagenia. (*Stove Epiphyte*) Orchidaceæ. Gynandria Monandria.—This fine plant was sent to the Horticultural Society from Guatemala by Mr. Hartweg, who found it in the mountains of Salama, in the province of Vera Paz, also near the village of Sunil, near Quezaltenango, in Guatemala, growing on rocks, at an elevation of about 7000 feet above the sea. In May, 1843, it produced its flowers, and ever since has been in such bad health that it is doubtful if it will survive. In habit the species is so like some of the Peristerias with pendulous racemes, that it would certainly be mistaken for them; and in structure it approaches them no doubt very closely. It is, however, essentially distinguished by the labellum and pollen apparatus. In Peristerias the labellum, although having a moveable joint in the middle, is continuous with the column by a thick fleshy base; here the articulation at that part is very conspicuous. The Peristerias have four pollen-masses; here we have but two. And, finally, the strap by which the pollen-masses cohere is long and slender, like that of a Lycaste, not deficient, so as to render the pollen-masses sessile upon a crescent-shaped gland as in Peristeria. The flowers of this plant are formed in a pendulous raceme, as much as 18 inches long; the lower part being clothed with distant short blunt scales, which extend into bracts about half the length of the pedicels. Each raceme consists of nine or ten flowers of a dull greenish-yellow, covered externally with short hairs; their petals have three streaks of violet; their lip is downy all over the upper surface, dark purple in the middle, with two or three spots of the same colour near the point. In the centre of the lower half is a large shaggy hump. It may be grown in a wire basket like a Stanhopea, or tied to a block of wood and suspended to a rafter, in a moist stove. If potted in the usual way, the flower-spike will be apt to go down into the soil and perish. Like many other Orchidaceous plants it requires an ample supply of water during the growing season, and shade in sunny weather, at a temperature between 80° and 90° by day, but not above 70° at night. Towards the end of October water should almost be withheld for a few weeks, no more being given than will prevent the pseudo-bulbs from shrivelling.—*Botanical Register.*

Garden Memoranda.

Mr. Scambler's, West Green, Tottenham.—There is now in full bloom at this place two fine standard trees of the Tamarix gallica, or French Tamarisk. They are about 11 feet 9 inches in height, and each head measures about 5 feet in circumference. This elegantly-drooping slender-branched shrub is well known in gardens, but is seldom that it favours us with so rich a display of its pretty clusters of reddish-coloured blossoms. It is exceedingly handsome as a standard, and is well suited for ornamenting shrubberies, being perfectly hardy, and thriving well in almost any soil or situation. It may be increased freely from cuttings planted in the open ground in spring or autumn.

Miscellaneous.

Cultivation and Planting of the Ranunculus.—The soil should be trenched 18 or 20 inches, and composed of good rich loam, to which add ⅓ part of very old, well rotted cow manure, and the same quantity of clay broken into small pieces; add to this a little sand, and thoroughly mix the whole; if the soil binds, add some sandy peat; make the bed on a level with the path or walks; the plants would do better if the bed was *below* rather than *above* the level. Having prepared the soil, as above, sometime during the summer or autumn, take the *earliest* opportunity in the succeeding spring to stir up the bed one spit deep, and take off 1½ inch of the soil; then place the plants in an upright position on the surface, 6 inches apart each way, and replace the soil carefully, which will cover the crown of the Ranunculus about 1½ inch; deeper planting would be injurious. After the plants appear, keep them free from weeds, and press the soil firmly around the plants after they get two inches high. If the weather prove dry, water them freely early in the morning, and shade them from the sun from 9 o'clock, A. M. to 3 o'clock, P. M. As soon as the foliage becomes yellow, take the roots up and dry them thoroughly in the shade, and keep them in a dry place. The Ranunculus loves a cool and moist situation, but no stagnant water should be permitted, nor should they be placed under the shade or dripping of trees. The morning sun, free circulation of air, and shade as directed, will insure success.—*Hovey's Magazine of Horticulture*

New Echites.—At the last meeting of the Horticultural Society, Mr. Lorraine exhibited a very fine twiner, under the name of E. carassa. Upon an examination of the writers on the genus Echites, it turns out that no such plant is recorded by them; it, however, proves to be the Echites crassinoda of Mr. Gardner, which the younger De Candolle has separated, with some others, under the name of Dipladenia, to which genus Echites splendens and atropurpurea also belong. The name of Mr. Loraine's plant will therefore be Dipladenia crassinoda.

CALENDAR OF OPERATIONS

For the ensuing Week.

I.—HOTHOUSE, CONSERVATORIES, &c.

FROM October to May the principal watering in the stove should be done before noon; and to the middle or end of January the house should be kept as dry as possible; a slight syringing, however, will be useful to keep the foliage clear from dust, &c. A sunny morning is the best time to water over head, and once in ten days will be often enough. All plants that require pruning or thinning out before the next growing season should be dressed at once, to give more room for the rest. Clerodendrons, Vincas, and other fast-growing plants which require large pots in summer, should never be watered in these large pots; turn them out, and shake all the soil from the roots, and replace them in as small pots as possible, their roots into, but do not prune the roots much at this season.

[illegible] may be applied to advantage [illegible] may be derived from [illegible], a week, in addition to the cultivation of its lip.

Conservatory.—From this time till late in the spring none Climbers in this house will require pruning, and thinning out, the whole of them will require a little dressing now and soon, especially where they obstruct the light. Where only the climber is grown, it must be pruned according to the time you want it to be in flower next summer—the earlier they are wanted to flower, the sooner they must be pruned. One great advantage in Climbers of this nature is, that most of them flower on the current year's growth, like the Grape Vine; all such ought to be very closely pruned at the final dressing. Some people are afraid to cut off much wood, and their plants soon get disordered; the Ipomœa Learii is the first to suffer in this way; when this plant has filled the space intended for it, the side shoots should be cut to the last joint next the old wood, and as the plant gets older many of these side shoots must be cut out altogether. The Ipomœa bona nox, although an annual, is well worth growing for a warm conservatory, on account of its fine large white flowers, which open at night; it should be treated as a biennial; sow it early in July, and keep it in 48 pots in the stove through the winter, harden it at the end of spring, and plant it out in a rich border in the conservatory about the end of May; it roots as freely from cuttings as the I. Learii.

Pits and Frames.—A very great disadvantage in storing plants for the winter is to have them in dirty pots, often covered with green and black slime, which creates damp enough to kill one half of the plants in them. Everything in and about plant frames ought to be kept as close and as dry as possible, until March at least. The lights should be taken off half hardy plants every fine day, and no rains or dews should be allowed to fall on the plants from this time until the turn of the season early in the spring; all that time the plants ought to have the benefit of all the sun-heat our climate affords, and no more fire-heat than will just secure them from frost.—*D. B.*

II.—FLOWER GARDEN AND SHRUBBERIES.

Out-door Department.

Now that the frosts have rendered the flower-gardens shabby for the season, the principal thing to attend to will be the storing of such plants as it is desirable to preserve for another season. I am not an advocate for preserving many old plants, but there are certain tribes which bloom all the better for being a year or two old. Among these I class more particularly Scarlet Pelargoniums and Shrubby Calceolarias, and therefore make it a rule to keep all the plants I can possibly find room for. Calceolarias I generally pot in the smallest-sized pots I can get them into, and if convenient, I place them for a week or two in a close pit, but if not, they are placed at once under the greenhouse stage, where they remain until they are turned into cold pits in spring. For Scarlet Pelargoniums I have a range of span roofed pits filled with tan, which at this season receives sufficient fresh material to excite a gentle fermentation in the whole mass. In this tan the Pelargoniums are planted, after being cut down, stowing them as thickly as possible, and the pits are kept pretty close until the plants have made some young leaves, after which they are inured to the air, and receive the same treatment as other plants, taking care, of course, to secure them against frost throughout the winter. In spring, about March, they are potted and placed in heat until they are well established, after which they are hardened off preparatory to being planted out in May. These plants are excellent for dwarf beds, as they do not grow so vigorously as young ones. Scarlet Pelargoniums may also be preserved in boxes securely packed in dry peat earth, but as I have no experience in the matter I had better refer the reader to an article on the subject in the *Chronicle* for last year, from the pen of Mr. Gordon. I also take up carefully such plants as Nierembergias and Mesembryanthemums, but Verbenas, Petunias, and the like, I do not consider worth the trouble.

Pits and Frames.—All plants in this department should be got in order for the winter as quickly as possible; those that are well established may be placed in their winter quarters at once, giving the most valuable ones the best places, but those that are not well rooted may be kept in heat a few weeks longer, for though theory may say, keep them as quiet as possible, practice, which is a much better guide, says, keep them growing until they are thoroughly established, unless you wish to consign them prematurely to the rubbish heap.

Reserve Garden.—Plants of Wallflowers, Double Rockets, Polyanthuses, Double Primulas, Hepaticas, and other spring-flowering plants that have been growing in nursery beds through the summer, may now be removed to their blooming quarters in the flower-borders. If you can surround them with fresh compost they will gratefully repay your kindness in the spring.—*W. P. A.*

III.—FLORISTS' FLOWERS.

Auriculas.—It will soon be necessary that they should be put in their quarters for the winter. Nine tenths of the collections grown in the country are wintered in glazed frames, or sheltered by boards hinged to a wall; the great point, however, is to keep them from drenching rain when the plant is in a dormant state. *Polyanthuses.*—May still be planted—the sooner the better. *Tulips.*—All offsets, seedlings, or unhealthy bulbs should now be in the ground, and as the main bed ought to be planted between the second week in October and the first week in November, everything must now be in readiness, and the first favourable opportunity taken of putting them in the ground. In consequence of the late fine weather the beds ought to be in a good state for planting, and it would be a wise precaution to cover them with mats during the night, or on the appearance of rain; as it is advisable not to plant when the bed is too much saturated with moisture. We promised last week to name a few first-rate and splendid Tulips, the price of most being high:—*Feathered Bizarre*, Dickson's Duke of Devonshire; *Flamed Bizarre*, Strong's King; *Feathered Bybloemen*, Louis XVI.; *Flamed Bybloemen*, Salvator Rosa; *Feathered Rose*, Lady Middleton; *Flamed Rose*, Beteral's Brutante éclatante. These are, comparatively speaking, but in few hands; but they are gems which no good bed should be without. *Dahlias.*—We have now had several sharp frosts; if the precautionary measures advised last week have not been adopted, it must be done forthwith. *Beds for Ranunculuses* should now be prepared, and all compost heaps turned and sweetened; vegetable refuse should be collected and put in heaps to decay.—*J. F. W.*

IV.—PINERIES, VINERIES, &c.

Pineries.—Those plants which are now in fruit, and those for fruiting next, should have a bottom-heat of about 85°, and a top-heat of from 65° to 68° at night; the day temperature varying according to the brightness of the weather. Supply the plants with water where necessary, letting the water be about the temperature of the bed. Strong plants swelling fruit may still have a little liquid manure with advantage. The night temperature should not exceed 60°, and should be allowed gradually to fall, so as to be about 57° at the end of this month.

Vineries.—To preserve Grapes to a late period is a matter of much importance to every gardener, and to keep them plump as well as free from mould and damp, requires close attention to the state of the atmosphere. In endeavouring to prevent damp, care must be taken not to overheat the house, as this will cause the fruit to shrivel. Where a stock of Vines in pots or boxes have been grown for early forcing, some of them should now be ready for bringing into the house; they should be well washed, and top-dressed if it was done last month. The pots may be placed in any part of the house till the buds begin to break. Fresh, hot dung is the best thing to start them into growth with; it may be laid along the centre of the house in the form of a ridge. Vines will not start at this season at a lower temperature than 60° at night.

Peach-house.—In most cases the trees in the house that was second last season will be in the best condition for starting first for next season's crop. When this is the case let no time be

out in putting the house and trees in order. Let the lights, rafters, trellis, and walls be well washed, and when dry give them a thin coat of paint or colouring. Dress the trees with a mixture of soft soap and sulphur in hot water: let this be well rubbed in with a sponge. See also to the flues or pipes being in good working order.

Melons.—The best way to obtain Melons of good quality at this season is to grow them in a late vinery, training them up a trellis under the Vines. We have the Cabul treated in this way, now ripening fruit of as good flavour as at any time of the year; as also the Hovenines has done in former years.—*G. F.*

V.—HARDY FRUIT AND KITCHEN-GARDEN.

Gathering and Preserving Fruit.—It is better to gather the later Apples and Pears, though not quite ripe enough, than to expose them to much frost, which, though it may render them sooner fit for the table, will prevent them keeping so long, and injure their flavour. All kinds may be gathered as soon as the stalks separate easily from the branches, but as some kinds adhere very firmly, the best criterion of fitness for gathering is to slice a fruit up the middle, and see if its seeds are approaching maturity. Care should be taken to keep all late fruit from light and from air, if it is desirable to keep them long. This should be particularly attended to in the case of those fruits gathered before sufficiently matured, or otherwise they will be disfigured by shrivelling, &c. The season of any favourite Apple or Pear may be prolonged by gathering at different times, and by subjecting the first gathering to a higher temperature, so as to promote the saccharine fermentation. Care should be taken that the increased temperature is not attended with too arid an atmosphere, or the juices of the fruit will be unnecessarily exhausted. Procure a quantity of clean sand, to be thoroughly dried, for packing the best fruit in pots and jars afterwards. Charcoal-dust may be used for the same purpose, after wrapping each fruit in tissue paper. I once knew of a quantity of Apples, and Carrots, &c., being rotted by packing in dry sawdust—the moisture escaping from the fruit, &c., causing the sawdust to heat violently. The fruit cannot be better dealt with at present than by placing them thinly on open shelves. Look after Filberts and Walnuts, and see that they neither become too moist, nor get too much dried, as in either case the kernel will be injured. Few things require more attention than fruit-rooms, as generally they have to be made the general storehouse for everything, such as nets, cloths, seeds, &c. It is to be hoped that the able observations of Mr. Forsyth will be promotive of a beneficial change.

Celery.—Proceed with earthing-up every favourable opportunity. Much good Celery is spoiled at an early season from want of proper attention. To secure very large fine heads of Celery for the first shooting parties in September, I generally earth-up at once (after being previously tied up), from a fortnight to three weeks before it is wanted for use. If such Celery is earthed-up gradually, many of the best heads will run to seed; if allowed to stand long after receiving one final earthing-up, the centre of the plant will rot. For succession crops, where there is little danger of the plants running to seed-stalk, soak the beds first with water, and then earth-up gradually, giving a little at a time, so as not to cover the centre of the plant. Moderate-sized heads answer best for general purposes, but gardeners, at times, must humour visitors by giving them something to look at. Where worms are very plentiful, strew the ground with ashes before earthing-up; or, if you can, put a little around each stalk as you proceed. Quicklime must not be used for this purpose, as, if it lodges in the heart of the plant, it will disfigure it as much as the worms would do. *Routine.*—See former Calendars.—*R. F.*

VI.—ARBORICULTURE.

Old Woods.—Attend to the directions given in late Calendars.

Coppice.—The above remark will equally apply to this department for the present; it is too early to commence planting.

Young Plantations.—The clearing of ground, taking up dead trees where it is intended to plant fresh ones, inclosing ground for new ones, trenching and holing, should now be forwarded with all possible dispatch, preparatory to planting.

Hedge-rows.—Take up dead trees, make holes for fresh ones, and consider what kinds to plant, so as to be the least detrimental to arable and pasture land; but at the same time select the kinds that will be most valuable as well as ornamental; planting should not be performed without due consideration.

Nursery Work.—As soon as the leaves begin to fall off deciduous trees, they may be taken up and laid in by the heels in well pulverised soil, until they can be replanted where they are intended to stand.—*W. B.*

VII.—COTTAGERS' GARDENS.

The taking up and storing away the various winter crops is now the principal thing to be attended to. When that is accomplished let the cleared grounds be ridged, or roughly dug, in order to expose as large a surface as possible to the mellowing influence of the winter frosts. All weeds and vegetable refuse should be cleared away to the manure heap. By this means the ground is rendered much neater, weeds are thus prevented from seeding, and consequently much labour is saved next year. Advantage should also be taken of fine days, of which many can scarcely be expected after this time, to clean every corner of the garden against winter. Let the flower border be stirred up and neatly raked over; remove decaying blooms from Dahlias. If fruit is not already all got in, look sharply after it: little will be gained after this time, but much lost, by allowing it to remain longer upon the trees. The best season for planting fruit trees is as soon as their leaves have fallen, provided the soil is sufficiently moistened to admit of the trees being taken up. By autumn planting, trees, &c., get pretty well established in their new situation before winter; they are thus better able to stand the cold easterly winds in spring, and are ready to commence growing upon the first approach of fine weather.—*J. M'H*

State of the Weather near London for the week ending Oct. 10, 1844, as observed at the Horticultural Garden, Chiswick.

Oct.	Moon's Age.	Barometer. 9 morning. Max.	Min.	Max	Min	Mean.	Wind	Rain

The highest temperature during the above period occurred on the 14th, 1841—therm. 71°; and the lowest on the 19th, 1843—therm. 29°.

Notices to Correspondents.

ASPHALTE COVERING.—*S.*—This was found to exclude completely the rain from a Vine-border; and, with a little straw under it, there is no danger to be apprehended from frost. In excluding cold rain and melting snow, borders must not, however, be allowed to get too dry. As affording protection from wet, Asphalte is preferable to a double mat for covering plants; but it requires to be fixed on frame-work.‡

BOOKS.—*G. W. G.*—Mr. Hoare's work does not treat of Vines under glass. Take that by Mr. Roberts. Glendinning on the Pine-apple will suit you best.

CLIANTHUS PUNICEUS.—*The Cid.*—If your plant is attacked by green-fly, fumigating with Tobacco will certainly destroy them; but in such a season as this has been, it is more likely to be red-spider (which causes the leaves to drop off), on which Tobacco smoke has no effect. It is a plant which will not bear much cutting in autumn, especially in cold weather, therefore you had better defer cutting it down until spring.‡

CHRYSANTHEMUMS.—*The Cid.*—Cut down any plants of these that are too small to flower this season, and keep them in a cold frame until spring. Much better plants will be obtained from spring cuttings than by dividing the roots. See p. 676, vol. 1843.‡

FORESTING.—*J. M. F.*—Never give manure to Fir-trees, or indeed any kind of Coniferous plants. The non-resinous trees will bear it, and Oaks or Spanish Chesnuts will do the better for small quantities; but the best preparation for all forest-trees is a thorough loosening and pulverisation of the soil; to which may be added the ashes of all refuse, such as weeds, burnt upon the ground. A little super-phosphate of lime, sprinkled over the roots when planted, has been found to quicken the formation of new fibres.

FRUIT-TREES.—*Farmer.*—You may apply the strongest liquid manure from the farmyard, or elsewhere, with great advantage to Pear and Apple-trees if you mix it with plenty of water.‡

GUANO.—*M. W. K.*—The rod, imperial measure, of 30¼ square yards is that understood, and for which 4 or 5 lbs. was recommended. Well diluted, it may be applied either before the ground is cropped, or when the plants are a little above ground.‡

HEATING.—*Albert.*—Certainly. You will have ample top-heat with such pipes. Do not even run your flue inside your house. It is to be feared that your bottom heat may be insufficient, and you had better let the pipes employed for that purpose double back, so as to increase the heating surface. You must have moisture, and you may make shift with lead or zinc troughs, but both those metals are objectionable, because of their softness, especially when heated. Your boiler will do very well.

HYACINTHS.—*L.*—Hyacinths which have been grown in pots in the usual way, may be removed into glasses when the flowers begin to show colour. The bulbs should then be gently shaken from the soil, the roots washed in luke-warm water, and placed in the glasses, which should be filled with water of the same temperature.‡

INSECTS.—We must beg our correspondents to send us specimens with their queries, and living ones of larvæ if possible, in order that we may rear them to study their economy. It is impossible to tell the owner of the *Beurré Diel Pear* tree what his larvæ are without seeing specimens. *R.*——*Siler.*—The best means of getting rid of house crickets is to take some bread, sweeten it with sugar, and add to it some oxide of arsenic, then place portions of it wherever the crickets congregate; but as it will poison any animal it must be carefully used. *R.*——*J. H.*—Your live caterpillar arrived safe. It is the larva of the Death's head Hawk-moth, Acherontia Atropos, whose history with figures you will see in Curtis's Brit. Ent., fol. and pl. 147. *R.*——*F. H. S.*—Cynips lenticularis, or an allied species, causes the Oak-spangles, and you will find an account of them in the 3d vol. of the *Gardeners' Chronicle*, p. 52. *R.*——*R. W.*—We beg you will transmit Mr. Curtis specimens of the flies in a quill. The fever could not produce them; and if you burn sulphur matches, or brown paper previously washed with sulphur, upon a piece of old wire sieve, laid over a flower-pot, it will suffocate the flies; but the doors and windows must be made as air-tight as possible, and if the pot be placed in a large dish or tin, no danger need be apprehended. All picture-frames, &c. must be removed to avoid being tarnished. As Hayes is not within the limits of the two-penny post, it is necessary that communications should be sent to Mr. Curtis *before* Wednesday, where an immediate answer is desirable. *R.*——*P. R.*—Your Datura is infested with Aphides: the application of Tobacco smoke will extirpate them. *R.*——*C. McGregor.*—Your quill contained no beetle nor anything that we could find, excepting a minute portion of dried vegetable. If you will oblige us with sufficient materials we will with pleasure investigate the subject. *R.*——*J. C. M.*—I should like much to receive living specimens of your Palmer-worm, as it is very desirable to breed all the noxious insects. The maggots attacking your Cabbages you will find figured and described in the 4th vol. of the Royal Agricultural Journal, p. 128, and pl. H. fols. 32 and 33. *R.*——*Anon's* female Ichneumon is named Pimpla instigator, *vide* Curtis's Brit. Ent., fol. and pl. 214. It is useful in keeping under the larger hairy caterpillars in gardens, by depositing its eggs in their bodies. *R.*——*Rufo.*—We will consider your plaintive notes, and endeavour to sing in praise of your ill used race.

MELONS.—In a frame only 3½ feet wide, with three plants under each light, you could not have had much fruit.‡

MORPHOLOGY.—*A Constant Reader.*—Your plant is no illustration of this subject, but a specimen of common purslain, the seed of which has been mixed with Port. Thellusonii, &c.

NAMES OF FRUITS.—None of our correspondents are unreasonable. We are willing to name doubtful specimens of fruit; to a moderate extent; but we cannot sit down to give the names of scores of things which everybody ought to know.——*J. C.*—Has just sent a box of 33 kinds to be named, and we must put a stop to such merciless demands upon our time.——*Veritas.*—1, 2, Brown Beurré; 3, 7, Old Colmar; 4, Buchanan's Spiing Beurré; 5, Spanish Bon Chrétien; 6, Beurré de Capiaumont; 8, 12, Marie Louise; 9, 10, Flemish Beauty; 11, Glout Morceau.‡

NAMES OF PLANTS.—*T. C.*—Stanhopea Lindleyi, a variety of S. oculata.——*J. D.*—Oncidium concolor.——*W. K. P.*—1, Rhipsalis grandiflorus (?); 2, Mammillaria subcrocea: 3, Epiphyllum alatum; 4, Rhipsalis salicornioides; 6, some Opuntia; 8, Euphorbia polygona; 9, Mammillaria pusilla; 5 and 7 are indeterminable.‡——*C. C.*—Quercus Phellos.¶

PEAR-TREES.—*Farmer.*—The following varieties are most likely to succeed on a high situation:—Aston Town, Knight's Monarch, Althorp Crassane, Passe Colmar, Hacon's Incomparable, and Ne plus Meurs. On such a situation they will succeed best trained in the dwarf form. As your ground is rather heavy, it should be well trenched and manured with farmyard manure, mixing it well with the soil. To plant a tree properly you have only to spread its roots a little sloping, and so as not to be much below the surface when covered with soil, made sufficiently fine for closing about the roots on immediate watering.‡

PLANTS.—*F. H. S.*—The following are good greenhouse plants, viz.:—Veronica speciosa, Choroszema varium nanum, Pimelea spectabilis, Hovea pungens, Leschenaultia grandiflora, Mirbelia dilatata, Statice Dickensoni, Tropæolum azureum, Tetratheca hexandra, Habrothamnus fasciculatus, *H. cyanocalyx*, Boronia crenulata, Eriostemon buxifolium, Correa alba, *C. rubicunda*, *C. reticulata*, Tecoma jasminoides rosea, Ruellia ovata, Cuphea strigillosa, and Manettia bicolor, *M. macrophylla*. The following are suitable for a stove:—Achimenes picta, Achimenes longiflora and Achimenes grandiflora, Clerodendron infortunatum, Aphelandra cristata, Ixora coccinea, Eranthemum pulchellum, Euphorbia splendens and E. jacquiniflora, Franciscea unifiora, Gloriosa superba, Gloxinias, Ipomœa Horsfallia, Justicia picta and *J. speciosa*, Kendelsia speciosa, Ruellia juncea, with the different kinds of Tuberous-rooted. The best soil for potting Hyacinths in is good sandy loam and leaf-mould in about equal portions. ¶——*A Subscriber.*—The time when the following plants flower, if treated in the ordinary way, and not forced or excited by any artificial means, is as follows:—Jasminum revolutum, June and July: it lasts in bloom about a month; Rhododendron caucasicum album, August, 2 weeks; R. c. roseum, April, do.; R. chamæcistus, April, do.; R. Nobleanum, April, do.; and R. pulcherrimum, April, do.; Rhodora canadensis, May, do.; Sternbergia lutea, October, 1 month; Berberis empetrifolia, May, 2 weeks; B. (nervosa) glumacea, March, 2 weeks; B. Aquifolium, March and April, do.; B. dealbata, May, do.; Andromeda Catesbæi, June and July, 1 month; Camellia, single and double (open air), April, 2 weeks; Thea viridis, August, 1 month; Althæa frutex, September, 2 weeks; Daphne mezereum autumnalis, October, 1 month; D. neapolitana (various), June, do.; and Fritillaria pracox, March, 2 weeks. The duration of blooming depends greatly on what kind of weather there is at the time; if moist they will last much longer and later, but if dry or cold much shorter. ¶

POTATOES.—*A.*—Chapman's Potato, planted early in spring, is a good Kidney for a supply between the earliest varieties and the American Natives.‡

PRIMULA SINENSIS.—*The Cid.*—It is very probable that your plant has been attacked by some insect. It will succeed best in a cold pit in summer, where it can be shaded and sheltered from heavy rains. Young plants will be apt to damp off in a cold frame in winter. ‡

WALNUTS.—*Nutworth.*—To preserve these effectually, requires some care. They should be allowed to hang upon the tree until the outer covering begins to crack; in this state, when the tree is beaten, many of the Walnuts as they fall will roll out of the husk. These should be gathered into a basket separate from those that retain their covering; the latter should be laid aside for a few days until the husks burst, and they can be taken out with care. The great object is to prevent them from becoming mouldy; they should, therefore, be wiped clean and dry, and laid on a shelf in a dry place where they can have a free current of air until all tendency to mouldiness is overcome. Great care must, however, be taken that they are not over-dryed, for that will cause shrivelling. When sufficiently dry, they should be put into boxes in layers alternately with bran, fine dry sand, or shreds of cloth, and kept for use in a cool dry situation. By this means they will retain their moisture and flavour, and the film will with ease peel off.‡

MISCELLANEOUS.—*G.*—The fruit of Pyrus japonica is unfit to eat, because of its austerity, but not for any other reason. It is, in fact, a sort of Quince——*Z. Y. X.*—The cheapest preparation of copper which you can obtain is the sulphate. If used in sufficient quantity it will prevent the growth of weeds, but it will be an expensive remedy. Labour, constantly and skilfully applied, is by far the best and cheapest remedy for weeds.——*N. A.*—Gesnera zebrina naturally dies down when it has done flowering, after which it should be kept dry until the month of March. Cereus speciosissimus will flower in a conservatory border, providing it can be kept dry during winter.‡——*Delta.*—Directions for preserving Pelargoniums over winter are given in last week's Paper, p. 672 ‡——*M. W. K.*—No. 1 is considered a first-rate flower; the best of the purples. 2, crimson, a good show flower; 3, rose, free bloomer, with large trusses; 4, singular in colour, but not good in form.*——*G. H.*—You will find much information respecting the management of Fuchsias given by Mr. Wood, in former numbers of the present year. Pelargoniums like a rich light soil. Respecting their winter treatment, see our Calendar of Operations in to-day's paper.‡——*O. P. Q.*—Mr. Paxton is of opinion that the manner in which the conservatory at Chatsworth is glazed is a great improvement on the old method of glazing ‡——*A. B.*—We do not understand your question.‡——*W. S.*—We cannot decipher such Chinese names; seeds are not worth cultivating.‡——*Revertens*—A Pear can be grafted on a Crab or Apple-tree, but it will not stand long. The time for introducing Strawberries into heat varies according to the month in which the fruit is wanted; if wanted early, they should be put under glass before December. Allow the crowns of your Pine-apples to lie on the surface of a bark-bed for a few days, then pot them in a mixture of one-third loam and two-thirds of half-decayed leaf-mould, in which they will root very freely; afterwards plunge them in a frame, but not in too much bottom-heat, for that will injure the roots. Pelargonium-seed of this year's saving, as well as that of Roses, will probably grow if sown next spring. Plant your Vines inside the house. The long-rod system of training looks neatest in a greenhouse.‡——*J. H.*—It is not at all unusual for Orchidaceous Epiphytes to form fruit; if you set their flowers they generally do so.——*X. Y. Z.*—If you have no agent or correspondent at New York to whose knowledge of such business you could trust, you had better consult your solicitor, who, if he lives at your port, probably may have. *W.*

SEEDLING FLOWERS.

FUCHSIAS.—*R. S. J.*—The larger variety is the better of your two seedlings, and though large and showy, the tube and sepals are coarse, and possess too much colour.*——*B. B.*—None of your seedlings are equal to the sorts in cultivation; 3 is the best, but the tubes and sepals possess too much colour.*——*G. C.*—Your seedling is a very pretty variety, but it depends upon the habit of the plant whether it is a variety worth cultivating.*——*G. S.*—The darker seedling of the two wants novelty of colour to recommend it as a variety for general cultivation; it is pretty in form, but in its general appearance too much like many already out. The light variety is a very stout flower, wanting a deeper corolla; tube and sepals delicate vermillion, the latter tipped with green; corolla vermillion also, rather deeper than the tube.*——*W. J. C.*—Your seedling is a pretty little flower, singular in form, and appears to be a most prolific bloomer.*——*W. J. B.*—Your seedling is a very pretty and striking variety, and deserves a place in every collection; there is a slight tinge of pink in the tube, which changes to white in the sepals, and these, which are long and expanding, terminate with green points; rosy purple corolla; flowers of moderate size.*——*E. S.*—The light variety wants more colour in the corolla; this part of the flower has too faded an appearance. No. 3 is a fine pink-coloured variety, very much like but inferior to *T. Eximia*.*——*Anon.*—2 blooms in a letter. The sepals are too long, and there is rather too much colour in the tube. It resembles many we have seen this season.*——*O. P.*—The seedling Fuchsias you have sent are merely repetitions of sorts that have been some time in cultivation; the best among them is No. 4, being large, clean, and brilliant in colour; but they all resemble sorts in cultivation*.

DAHLIAS.—*Amateur.*—Your seedling is a very pretty variety, beautiful in colour, but a similar flower of greater substance, and with a stronger marked eye, is already in cultivation, named *Welsh's Blue Perfection*.*

VERBENAS.—*J. H.*—The lighter variety, a delicate rose, is very large, and from its appearance is of greenhouse cultivation; it is a good variety, but we prefer the smaller flower, which is very brilliant in colour, and appears less liable to fade; it is also less common in private than the larger one.*——*W. H.*—Your seedling has fine variety, the growth is large, and form a fine close set of pale, rosy-red colour.*——*A. A.*—Your seedling is not equal to many of the same colour at present cultivated.*

EDINBURGH VETERINARY COLLEGE.—The COMMITTEE of the HIGHLAND and AGRICULTURAL SOCIETY of SCOTLAND, appointed to superintend the Veterinary College, hereby intimate that PROFESSOR DICK will commence the COURSE of LECTURES on VETERINARY SURGERY and MEDICINE, for the 22d Session, on MONDAY, the 11th of NOVEMBER next. The Course will comprehend, as usual, instruction in the Anatomy, Physiology, and Pathology of the Horse, Neat Cattle, the Sheep, the Pig, and the Dog, including, also, Stable Management and the Forge; and, in order to the arrangement of the several departments of study at hours convenient for the Students, the Professor will have the assistance of Messrs. BARLOW and WORTHINGTON, Veterinary Surgeons, who, under his superintendence, will take charge of the Anatomical Demonstrations, Materia Medica, and Pharmacy. The necessary instructions in Chemistry, in connexion with the course, will be given by Dr. WILSON, instead of, as formerly intimated, by Dr. FYFE, who has been appointed Professor of Chemistry in King's College, Aberdeen.

By order of the Committee,
CHARLES GORDON, Secretary.

Highland and Agricultural Society's Hall,
Edinburgh, 4th October, 1844.

The Agricultural Gazette.

SATURDAY, OCTOBER 12, 1844.

MEETINGS FOR THE TWO FOLLOWING WEEKS.

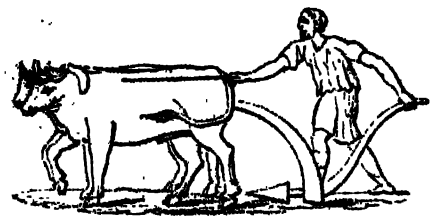
THURSDAY, Oct. 17—Agricultural Imp. Soc. of Ireland.

THURSDAY, Oct. 24—Agricultural Imp. Soc. of Ireland.

FARMERS' CLUBS.

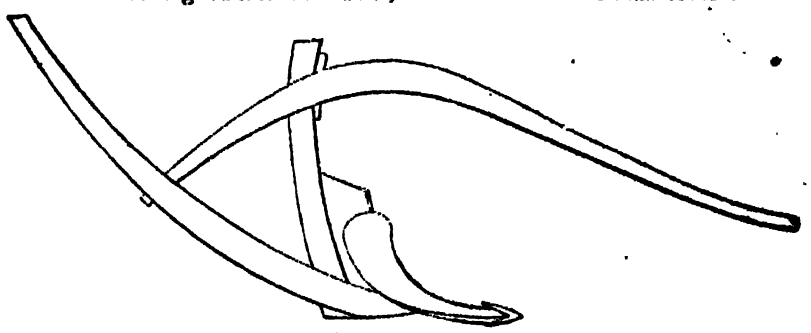
Oct. 21—Wenlock, Salford.
Oct. 22—Framlingham, Rayleigh.
Oct. 24—Richmondshire, Grove Ferry, Binfield and Waltham.
Oct. 25—Debenham, Stoke Ferry, Hadleigh.
Oct. 26—Gloucester.

WE are not aware that the advocates of the ALLOTMENT SYSTEM have had to contend with much active public opposition in the arena of argument. In endeavouring, however, to carry out their plans they have occasionally encountered an adverse feeling, more especially among farmers, which appears to be based on a misconception of the nature of the allotment system, and of the effects which it is calculated to produce on the labouring class. Farmers have been found to oppose its introduction on grounds such as these:—If a labourer works for his master during the usual hours of the day, and does his duty towards him, he will have neither time nor strength to expend in the cultivation of an allotment. To give him such an allotment is to place that in his way which will tempt him to deprive his employer of a portion of the time and strength he is entitled to expect from him; besides this, it will make him independent of his employer, and he will become a saucy and a bad servant.



Whether the labourer is in a position to cultivate an allotment should be considered in each individual case before the allotment is granted—the labour which his wife and family can give being taken into account. There are classes of labourers—waggoners, for instance—who have to devote all their spare time to the service of their employer; but if a man even in this position has a family capable, with occasional hired assistance, of cultivating an allotment, we see no objection to his possessing one. The general class, however, of day-labourers working 12 hours per day are able, where they have families to assist them, to cultivate an allotment of land, without any neglect of their duty to their employer. In proof of this, we refer to the evidence which we have already adduced. And will the possession of an allotment make the labourer independent of his employer, so as to become a saucy and bad servant? Read the evidence contained in our two previous Articles. In the first case quoted, 30 families were provided with 29 acres of allotment land—nearly an acre to a family. What is the result? "The tenants and their families have been rendered all honest and respectable; *they have been kept entirely free from parish relief, and become the farmer's most steady and industrious labourers.*" Look at the case of Long Newnton, Wilts. The rates paid in six months, from October, 1820, amounted to 208*l.* 6*s.*; while those for six months, from October, 1823, after the introduction of the allotment system, amounted to only 4*l.* 12*s.* 6*d.* "The labourers were reclaimed from idle and bad habits, and became most valuable servants."

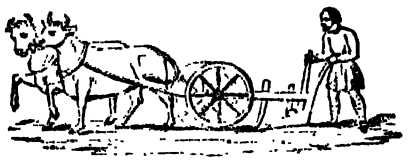
The labourer possessed of an allotment would be more independent than at present, it is true, and of many of the benefits which the allotment system can confer, this independence is the source. The man ceases to live from hand to mouth. If thrown out of work for a short time, he is not reduced to the brink of starvation, nor driven to the parish for relief. Such independence as this it is desirable and right, whether in a moral or a physical point of view, that the labourer should possess; but if the labourer still depends on wages for his main support, he cannot be independent of his employer. Indeed, every class and every individual in the community are reciprocally dependent; and this is a wise and beneficent arrangement.



We may safely believe, and act upon the belief, that the allotment system, where properly regulated, is beneficial to masters as well as labourers. The best method of effecting its general introduction, and of promoting its beneficial operation, will be considered next week.—*F.*

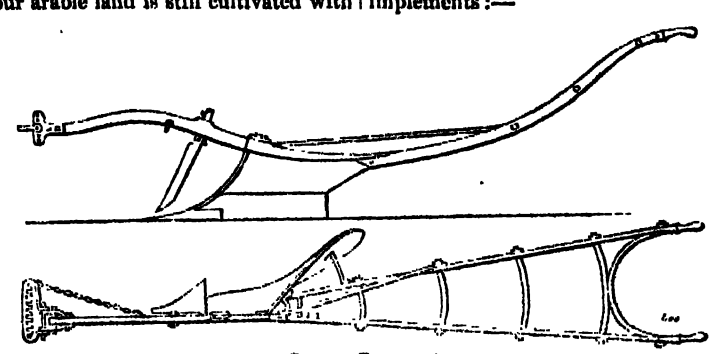
IN the course of our REMARKS ON THE PLOUGH, we do not at present intend to enter into any detailed statement of the considerations which should determine the merits of its various forms; this branch of the subject will be more suitably taken up hereafter in another section of our Paper: our present object is merely to impart a general idea of the character of the implement as now used in various parts of the kingdom.

It would serve no useful purpose to enter here into any antiquarian detail. The form of the plough in ancient times, much resembling that in the less civilised parts of the world at the present time, is described with sufficient minuteness by Mr. Ransome in his excellent work on Agricultural Mechanics, to which we have already alluded. We are indebted to the kindness of that gentleman for the following figures from his volume, which, without further remark, are sufficiently indicative of the inefficient form of the implement with which the unskilful agriculturist was then satisfied.

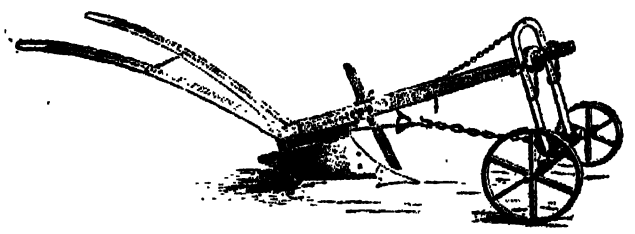


ROMAN PLOUGH.

CHINESE PLOUGH.



The following figure of a plough, taken from a Saxon Calendar, exhibits an improved construction. The mould-board, coulter, and wheels are much the same as those which are still used in many districts.



SAXON PLOUGH.

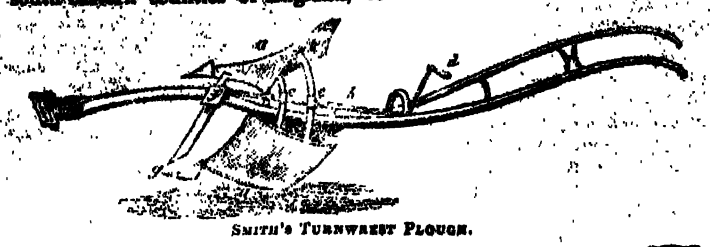
Ploughs may now be divided into those with fixed mould-boards, and turnwrest ploughs; and into those with wheels, and swing-ploughs. By much the greater part of our arable land is still cultivated with implements having fixed mould-boards. Turnwrest ploughs, by which, as a slight consideration of their construction will show, the furrow-slices are all thrown one way, are not suited for naturally wet and undrained lands. Such lands as are not thorough-drained require to be ploughed into ridges, so as to insure a surface drainage. Of the fixed mould-board class accordingly we have the greatest variety, suited—we do not say to our various kinds of arable soil, for variety in this, however great, would not justify the extreme variety which exists in the form of the plough—but suited to the custom and perhaps the prejudices of the several districts of the country.

The following figures exhibit some of these implements:—

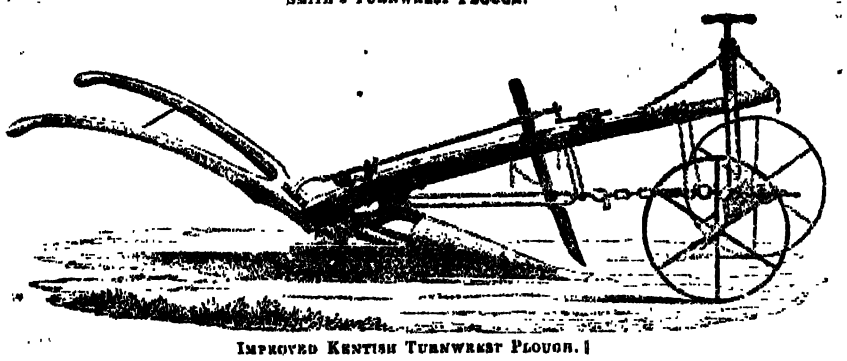
SCOTCH PLOUGH.*

BARRETT AND EXALL'S, A. 5, TWO-WHEEL PLOUGH.†

BARRETT AND EXALL'S, D. F. ONE-WHEEL PLOUGH ‡



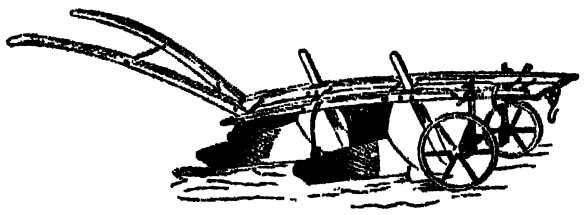
BARRETT AND EXALL'S TWO-WHEEL OR SWING PLOUGH.§



We hope on a future occasion to be able to state the comparative draught of some of these implements in executing a given quantity of work on various soils. The following are figures of two of

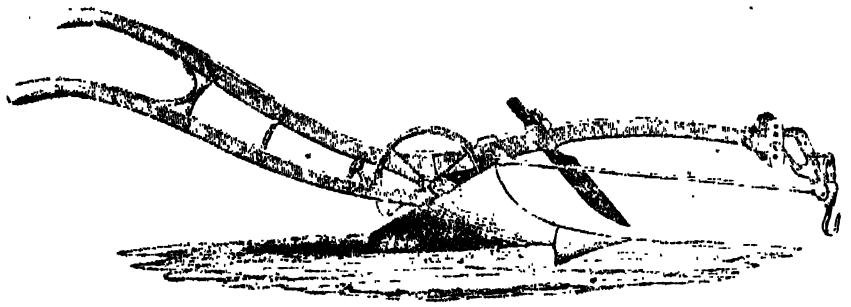
* Price 3*l.* 10*s.* to 5*l.* † Price 4*l.* 10*s.* ‡ Price 3*l.* 3*s.* § Price 4*l.*

two varieties of turnwrest plough in use; the one, common in the south-eastern counties of England, and the other, such as Mr. Smith, of Deanston, recommends on well-drained land.



Smith's Turnwrest Plough.

Improved Kentish Turnwrest Plough. †



Besides these, two other forms of the turnwrest plough were mentioned in our report of the Implement Yard at Southampton:—Lowcock's, a very ingenious and easily-managed implement, exhibited by Messrs. Ransome; and an exceedingly simply constructed plough exhibited by Mr. Comins, of South Moulton, Devon, descriptions of both of which will be found at page 513.

We have still two contrivances to mention connected with this implement; the one here figured, which is suitable on light soils where less than the power of two horses would be sufficient to draw an ordinary plough through the land, consists in uniting two implements together, so that a team of three horses, or perhaps of two strong ones, may turn two furrows at once.

Double Plough. ¶

The other matter to be mentioned is a mode of construction adopted by some makers, which, it would appear from the experiments on the draught of ploughs, by Mr. Pusey, as reported in the English Agricultural Society's Journal, is well calculated to diminish the power required to work the implement. This consists in the substitution of a wheel for the sole-plate of the plough; the friction on which—owing to the weight of the implement, which it appears is the cause of a considerable portion of the draught—is thus to a large extent diminished. The following figure exhibits the simplest and also the oldest of the modes of construction on this principle.

Wilkie's Friction-Wheel Swing Plough.

It will be seen that our object in the above very general remarks is simply to place on record a description of the plough as it is at present constructed and used in this country. The merits of the various forms of it, and the considerations on which these must respectively be determined, will afford materials for several future Articles in another section of our Paper.

THE ANOMALIES OF AGRICULTURE.

If there be upon this earth a pursuit—a practice, an art—call it what you will, of which one may at once with courtesy and truth say it is "as old as Adam," that art is the cultivation of the soil; or, to speak more like an honest Saxon—farming. It dates from the fall; it was the first fruit of the taste of the forbidden fruit. It is the proper biography of man, for it is coeval with the existence—nearly co-extensive with the spread of the human family upon earth. Born the child of sin and sorrow, it grew up the parent of good and of happiness; pronounced as a curse, it has turned a blessing. It is, as it were, the natural condition and obligation of man, in all ages and in all parts of the earth; and, could we indeed trace and follow out its history, it would probably be the most pregnant, the most real history of the human race. Adam and his children, Noah and his sons, the Jewish patriarchs, were all farmers. The heroes of Homer and of Hesiod, equally at home in the field of swords and ploughshares, settled all accounts in stock—not Government but agricultural—stock proper. Their *modus estimandi* of a warrior was by his flocks and herds; and their grandest religious ceremonial—the Hecatomb—must have been a perfect Smithfield Show. Cincinnatus, and the pastoral poets after him, were as much stock-masters. Cincinnatus among the ancients, Virgil, Horace, Cicero, and Pliny, among the more modern Romans, were all farmers. In a word, from the days of Adam to those of John Robinson*, and from him to the noble reigning triumvirate, Richmond, Spencer, and Pusey, farming has held up its head in the world as high as the most devoted agriculturist could wish to ambition.

* [illegible] Farm's farming colleagues.

Is it not, then, a something to wonder at, even in these latter days, when wonder itself is grown threadbare and out of fashion, that agriculture, being such, of human arts the elder brother, the most universal, the most necessary, should in this ignorant present time, to wit in the fifth decade of the 19th century, be of sciences the youngest and the last-born, not yet out of its swaddling clothes—and what swaddling-clothes! Prejudice wrapped over Ignorance, and a veil of thick and stupid mystery over all; as if the closer gaze of that which to know fully must be the most valuable and precious of all physical knowledge were a boon too rich and rare for thankless man. And yet, in plain and sober seriousness, can this be denied? Take the ordinary English farmer of 100, 200, or 300 acres; ask him the simplest question that can be put to a child, about any one branch of any one of the sciences upon which his whole practice is founded, and upon which his livelihood depends; take him to his dunghill, and ask him the meaning of decomposition; take him to his fresh-sown field, and ask him about germination; show him a field in broad leaf, and ask him the history of vegetable nutrition; ask him any one of these questions, or, if you can think of [illegible], something more simple and elementary than either. He is a professed dealer with Nature; he ploughs, manures, and limes; he sows and reaps; he is the autocratic director of every operation on his farm, mechanical and chemical. Surely if science be not all a lie, and the analogy between the laws of one material pursuit with another a delusion, he should be approaching beyond a mere empiric; he should have some conception of the great laws and principles which govern [illegible] the business; some [illegible] for the [illegible] that does he [illegible] of them as a soldier in the ranks, of the plan of a campaign; about as much as the foretopman of an Indiaman, of the position of his vessel from the occultation of a satellite of Jupiter; probably less than either of these. But I am told, in answer to this, that of late years there has been much improvement; that this state of things is passing away; that already the farmer (such a one, at least, as you would accept for your tenant) is an improved existence; that example farms, agricultural colleges, and schools of chemistry, are multiplying over the land; that the very technical terms of chemical lore are beginning to be heard at farmers' ordinaries; till the most fastidiously scientific appetite is beginning to pall, even with the food that pleased it best. This is indeed true enough; and away with the miserable conceit that, standing on the vantage-ground of a luckier education, would throw one jeer or permit one ill-placed smile to creep out at the infant efforts of however adult a mind, if the tendency be in the right direction. What if Farmer Dobson did think last year that ammonia was "the name of a gentleman's daughter?" He knows better this year, and next year we shall hear of his putting sulphuric acid to his dunghill, to seize this fair lady as she flies. Why should he be expected to be a ready-made chemist? When he was a boy, chemistry was scarcely born. He had no education in chemistry. How should he know anything about it, or that it had any more to do with farming than the Egyptian hieroglyph? He is not the person to be blamed. The blame, if anywhere, lies with those who advance it—namely, with the scientific world, who have allowed the physical world to grow nearly six thousand years old, and have only just made the notable discovery that the science of all nature—chemistry—is eminently and necessarily applicable to the art of all existence—farming! I say it is the backwardness and infancy of science, not the ignorance of farmers, that deserves reflection. Which of these three propositions is the more wonderful, that Jethro Tull should have made the discovery that pulverisation was the great secret of mechanical cultivation; or that Humphrey Davy should have first thought and lectured upon chemical cultivation; or that both these great secrets were not put into words till the surface of the earth had been tilled for upwards of 5700 years! It is true, Wheat has been sown, as well as "blood spilt ere now in the olden time;" and sooth to say, God's earth has been well enough manured by the one, to account for some extra luxuriance of the other. Lean stock has been made fresh, and fresh stock fat; yet around these simple-seeming operations, a veil of ignorance, of blindfold and gregarious empiricism has hung, to be torn aside by the magic touch of Davy first, in England, and after a pregnant interim, by Thaer and Liebig in Germany, Boussingault in France, Johnstone in Scotland, Buckland and Daubeny at Oxford, Henslow at Cambridge, and Playfair in London. And at the heels of these champions of agricultural Christendom, a host has gathered that promises to scare Prejudice herself from her favourite and oldest haunt; and strange to tell, the occupation that has hitherto been deemed "of the earth, earthy," dull, heavy, and changeless, stupidly laborious and mechanical, fitted only for the hard hands of peasants, and the unlettered scull of the hind and serf, receives at one blaze its brilliant illumination, and is all at once found to be associated with the profoundest discoveries, and dependent upon the most delicate and recondite investigations of physical science.—*C. W. H.*

(To be continued.)

GEO-AGRICULTURAL NOTES OF SOUTH GLOUCESTERSHIRE.

(Continued from page 544.)

Coal.—The coal strata, which next engage attention, do not follow the same law of conformity which those hitherto described have exhibited. The strata of the new red sandstone overlie them in a manner different from that in which the former are overlaid by the lias. In the latter case, an entire bed of the one rests on an entire bed of the other; but in the former, the new red strata rests on the edges of the coal strata; these must, therefore, have been raised up and worn away during the interval elapsing between their deposition and that of the strata covering them. The boundary of the coal district is easily traceable by Itchington, Cromhall, Wickwar, Sodbury, Waterleigh, Homeapple and Stonehill, Hanham, Keynsham, Brislington, Stapleton, and Winterbourn, inclosing a space of about 40 square miles. The greater portion of this boundary is the junction of the coal strata with those of the new red sandstone, which overlie them all round the southern edge of the basin. In the north of the coal district, its boundary is its junction with the millstone grit, which dips on all sides below it. Very few beds of coal occur in the northern part of the district, and these are of very inferior quality. Over almost the whole of the district, the prevalent rock is a siliceous sandstone, which, where coal abounds, alternates in thin layers with it, and with beds of clay and shale; but where coal does not occur, it forms extensive strata of most excellent building material. It is of a blue colour, but varies much in its texture. It is much quarried as a building stone, being the best, though not the handsomest material for that purpose in the county. It is also much used as a flag and paving-stone.

Agricultural Character of the Coal.—The poorest land in the county occurs on the clays of the coal formation near Cromhall and Rangeworthy. A great proportion of this land was lately in commons and wastes, and perfectly worthless. They were enclosed by Hayle, Wilkie, and [illegible] in general [illegible] the [illegible] no valuable [illegible] of [illegible] [illegible] [illegible]

extreme wetness, is not good. The fields are not large and the hedge-rows are crowded with the Oak and the Elm. Neither the arable nor the pasture-land are drained. There is no general rotation adopted; the land is cropped as it will bear it. The average crop of Wheat does not exceed two-and-a-half quarters; that of Oats cannot be put at more than 28 bushels. Very few Turnips are grown. The soil on the sandstone of the coal measures is a sandy clay—light when dry, but clinging together when wet. In some places, when near to the rock, it is brashy. It forms a good Barley soil, and good crops of Wheat are raised from it. There are few commons on it, and these are greatly more valuable as commons than those on the clay. About three-fourths of this district are in pasture, which is of good quality. Very little of it is drained. There is rarely any regular system of cultivation followed on the arable land. The centre of this district is crowded by a large population of colliers and others engaged in the coal trade, and the land is divided and subdivided among a great number of holders. The farms are very small. Wheat and Potatoes are the chief crops. Barley and seeds are grown occasionally. The average Wheat-crop per acre is below three quarters; that of Barley is about four quarters. The crop of seeds, after being mowed and depastured during one year, is broken up for Wheat or Potatoes in the next. The system of breaking up seeds for Potatoes is very common.

Millstone Grit.—This is the name given to the rock on which the coal strata lie. It is a siliceous sandstone, varying considerably in its texture: it incloses and forms the coal basin, dipping under the coal strata on every side. It extends from Itchington, where it is overlaid by the red marl, by Tytherington, Cromhall, and Wickwar, to Chipping Sodbury. This band is nowhere above half a mile in width: it is about 10 miles in length. Beside this, which is the greatest extent of the millstone grit, it occurs in the midst of the coal strata, dipping to the north and south, and forming a ridge against which those strata lie on either side. At Bristol it again makes its appearance: Brandon-hill consists of this rock. It occurs again at Almondsbury, in junction with the mountain limestone. A very small extent of it, however, is here exposed, being almost immediately covered up again by the lias clay. It occurs also at Doynton, where its junction with the mountain limestone is again exposed, the coal strata being, however, obscured by the red marl and blue clay. The country has been here curiously broken up by a fault, so that on crossing from Wick towards Doynton, up the ravine between the two places, we pass first over a tract of the millstone-grit, then over one of mountain limestone, again over a tract of a siliceous rock precisely similar to that first passed over; and in the bed of the river by Doynton, and in a small quarry near it, the mountain limestone again occurs dipping at an angle of at least 60°. All these rocks dip one way—slightly to the south-west. The only mode in which their appearance in this manner can be explained is, by supposing a fault to have taken place across the strata in the line of their strike. The millstone-grit varies very much in its texture. It is, at Kingsweston, a very soft sandstone; at Bristol it is very hard; at Wick it is a coarse conglomerate; at Cromhall, again, it is a hard siliceous sandstone, resembling that at Bristol; while, at Sodbury, it is a splintery rock in which the granular structure is entirely effaced.

Near Sodbury, Yate, and Wickwar, beds of strontian occur, overlying the millstone grit. I obtained some specimens in which fragments of the rock were imbedded in the material of the mineral, and which, on being taken out, left their impression, as if they had been enveloped when in a soft state. This mineral is not made use of, except in some instances, when pounded down as a finish to gravel-walks, over which it is strewed.

Agricultural Character of Millstone Grit.—The surface of the millstone grit is generally level and uniform. About three-fourths of it are in pasture. The fields are frequently much overshadowed by hedgerow-trees. The Elm is the tree which is natural to the soil. The pasture-land, beside being soured by the shade of trees, is very easily injured by dry weather. It is frequently very shallow, and is then easily burnt. Perhaps an average crop of 18 cwt. of hay per acre is mowed from it. The soil is generally a keen sand, and, where it is shallow, is full of the angular fragments of the rock. Near Sodbury it is a clayey soil, owing, probably, less to the disintegration of the rock, which is here extremely hard, than to that of the seams of clay by which it is separated.

The general rotation followed on the arable land is a four-years' course; 1st, Wheat, 2d, Barley, 3d, Seeds, 4th, Potatoes. It is a very general practice to leave the crop of seeds out of the rotation, and thus reduce the course to one of three years' duration. This makes it, on a sandy land, a very severe rotation, and under this system it is accordingly found necessary to fallow land occasionally. The average of the Wheat crop is less than three quarters, that of the Barley crop about three and a half quarters. Turnips are sometimes grown instead of seeds, and the average crop is probably less than 10 tons per acre. Lime is much used on this land. It is spread over the soil once in three years, at the rate of 80 or 90 bushels to the acre. It is said to do it good each application. Nothing but the farm-yard manure is applied to the crops, and the dung dropped on the pasture land is generally gathered together and placed on the arable land. No bone-dust is used for the Turnip crop. Indeed, it is nowhere generally used in South Gloucestershire.—*R. E.*

[ILLEGIBLE]-POTATO RAISED [ILLEGIBLE]

[ILLEGIBLE] have had completely without number of the failure of Potato crops, owing to the rain producing the rot, wet rot, &c., but the sort of failure which your correspondent "R." laments, in a late Number of the *Gazette*, and on which he asks your advice, we have not heard so much about, though I believe it is not uncommon, especially in small gardens.

I shall never forget one of these luxuriant failures coming under my notice when a lad. I had observed, when the early Potatoes were dug up, that wherever there was a plant with two or three good strong stems it was sure to afford Potatoes of a larger size than usual; and when I afterwards saw a crop where all the stems were large, I naturally concluded that the produce of Potatoes must be large also. I accordingly ventured to congratulate my grandfather on the abundant crop he was likely to have, the tops being nearly as high as myself; when he puzzled me much by saying that I was sadly mistaken, for they were all running to tops. How the Potatoes could run to tops I could not imagine; but in after years I fancied I had found a satisfactory explanation of the mystery, and I send it in the hope that it may be of use to "R." The sort of Potato of which I speak was a very valuable intermediate variety, known in North Lancashire as Lord Morris, or Murray's. It was a vigorous grower, and the deficiency in the produce I believe was owing to the ground being too highly manured (for a very powerful manure was used), and to the rows being much too near each other. "R." does not mention the distance at which his Potatoes were planted, but he does say the tops were magnificent—finer in many parts than he ever saw; that the ground was well manured with stable-dung, in many places with Potter's guano, and frequently watered with liquid manure, of human urine and soap-suds. The season cannot be to blame, as he suggests, for upon the whole it has not been unfavourable for late varieties; besides, we should have heard much more of it if the evil had been general. There can hardly be any doubt, in my opinion, that the frequent application of liquid manure was the cause of the mischief. Plants, as well as animals, may have too much of a good thing—they may be overfed; and it is an every-day observation that excessive luxuriance is opposed to fruitfulness. Facts in abundance might be mentioned in proof: I will state one. Col. Le Couteur, in his experiments with manures on Wheat, found that one application of liquid manure was injurious, but some Wheat to which liquid manure was a second time applied, grew so rank and full of leaves, that only a few plants produced ears, and the grain was worthless.

One of the most visibly bad effects of an excess of manure, especially of liquid manure, on Potatoes, is, that owing to their luxuriance, the stems are more brittle, and are much more liable to be laid by winds and rain, than if their growth had not been so rapid.

If your correspondent is aware of the functions of leaves, he will readily see the evils of this. Leaves are most important organs, and their use can hardly be too often explained and illustrated. All the matter which constitutes the Potato is prepared or elaborated in the leaves by the action of light, and consequently the produce of a plant must in a great measure depend on the quantity of leaves which it can expose to the light. If, then, by a too luxuriant growth, many Potato stems are laid, a considerable number of leaves must be shaded, and the crop of tubers must be so much less in consequence.

But if, in addition to this over-manuring, the rows are too near each other, the evil is much greater, the Potatoes now run to tops with a vengeance; the stems are drawn up, they are taller and weaker than if grown farther apart; the sap, as was observed by Mr. Knight, will have farther to travel, and more time will be required for its ascent and descent; and even if the stems should continue upright to the end—and it is hardly likely they could—there would even then be a less breadth of efficient foliage than if the rows had been at proper distances apart. In the latter case, almost every leaf might have been able to perform its functions, while in the former case the lower leaves would be shaded and useless. The plants would have presented a comparatively level surface—the uppermost leaves only would have been efficient.

Look at our woods. A wood where thinning has been wisely attended to, will yield a much greater weight of timber in a given time, than another wood where the trees have been left to themselves after planting. In a few years the branches meet, then intermingle, and the trees become engaged in a life or death struggle, fighting as it were for the precious light.

The cause of the difference in the weight of timber produced is obvious, for there must be a much greater breadth of foliage exposed to light by an acre of more or less cone-shaped trees, standing at proper distances apart, than by an acre of trees which are crowded.

There is another case which I may as well mention now, by which it is possible there may be a vigorous growth of stems, without a corresponding crop of tubers; and that is, where in a poor soil manure has been placed, as is the common practice, in the rows only. Some may be inclined to doubt this; but it was the opinion of the late Mr. Knight. In such a case he observed, the young plants grow very freely at first, because their first emitted roots find abundant nutriment, and these roots consequently extend rapidly; but they extend into the unmanured soil, and if there be not much, it cannot afford food. Abundant nourishment and consequently rapid growth of stem, with a scarcity of that nourishment, and the produce of tubers will naturally be small, comparatively with the growth of the plants.

If Liebig's theory of the summer nutrition of vegetables was true, this should be the best and most economical mode of applying manure, because we should then have the greatest amount of foliage at the least expense of manure. But as has hitherto been the faith of this country, plants depend upon the soil as well as upon the air for their food during the summer, as well as at any other period of their growth. We should, therefore, be careful to provide for their summer wants.

If "R." then, has any faith in the above remarks, he will withhold his liquid manure from his Potato crops next year, and so apply the other manure that his plants may live frugally, and not expend that in the production of superfluous stems and leaves which should have been reserved for the more important production of tubers. He will be careful also that his plants have sufficient breathing room, and that the rows of his late varieties be at least two feet apart. The object to be aimed at is to have the whole of the ground covered with foliage during summer, without the leaves of one plant interfering with those of another; this is a point of great importance in the culture of all plants producing grain, fruit, timber, or roots, and I am afraid is not yet sufficiently understood by the majority of those whom it more particularly concerns.—*J. Townley.*

ON THE ACTION OF GYPSUM, WITH REMARKS ON MISSTATEMENTS OF THE WRITER'S VIEWS.—By J. S. Henslow.

I am not intending in this communication to enter into any discussion respecting the fixation of ammonia by gypsum. I propose doing this on some future occasion, whenever I shall have been favoured with the returns I am still expecting to receive of my Schedule A. Can I hasten those returns a little, by requesting the several experimenters to forward them as soon as they conveniently can, or else to inform me of the reasons why they have not been able to fill them up? My present object is a word of advice to practical men, on a subject which is of quite as much consequence to them as the determination of a disputed point in agricultural chemistry. I would seek to impress upon them the propriety of extreme caution in attending to the advertisements of merchants who are recommending the novel manures which are now being applied to various agricultural purposes. I am not alluding to the adulterations of these manures, but to the applications of them. The public has already received due caution respecting the iniquitous extent to which such adulterations are carried on; as in the example noticed in page 259 of the *Gardeners' Chronicle* for 1844, where a substance was proved by analysis to have been adulterated to the amount of 97 per cent.; so that a farmer might be obliged to pay at the rate of 66*l.* per acre, instead of 40*s.* to produce a proposed effect. I pass by the dishonest dealer, and wish to speak of the advertisements of dealers whom I shall presume to be perfectly honest, but mistaken in the advice they give to the farmer. I find my name has been set forth as a guarantee for the efficacy of gypsum in its application to agricultural purposes, and therefore I have a right to caution the public against supposing that I have directly sanctioned what I certainly have not advised to the unqualified extent which might be supposed from the terms of an advertisement lately sent to me. I have not the slightest intention of impugning the motives of the advertiser, of whose firm I know nothing, any more than I know of any other firm dealing in this description of merchandise. But I must declare that he has gone far beyond anything I have ever stated in recommendation of gypsum as a fixer of ammonia. He may be quite right in his recommendation of gypsum for such purposes, and I shall be much surprised if it does not prove to be efficacious under peculiar circumstances; but his declaration of my views is much too unqualified when he says—"Sir John Herschel, Liebig, Professors Henslow and Johnstone, strongly advocate the addition of gypsum to liquid manure-tanks, and dunghills, for the purpose of fixing the ammonia." Surely any one who has seen and thought about what I have said in my "Letters to the Farmers of Suffolk," must have understood that I have hitherto been inviting practical men to make trial of the advice which chemists have given them concerning gypsum as a fixer of ammonia. In my Address to the Hadleigh Farmers' Club, which precedes those letters, I have stated at p. 15, that the subject had not yet been fully elucidated; and again at page 20; I have said "I will even venture to recommend (till good reason shall be shown against such a practice), that a little powdered gypsum be scattered from time to time over the materials (of the dunghill) as they accumulate; it can do no harm, and I believe may do much good. Let a sufficient quantity of water be sprinkled over it to wet the gypsum thoroughly." This exposition of the applicability of the views of chemists concerning the use of gypsum, is very far short of proving me to be a "strong advocate" for the use of it under all the circumstances named; and the letters which follow greatly qualify even the opinion given above; because I afterwards found that some chemists of reputation were doubtful of the gypsum proving effectual in dunghills. I wrote those letters with a view to provoke practical men to decide the question for themselves. I am not yet in a position to state the result of their co-operation for this purpose. I felt surprised also at finding the name of Sir John Herschel quoted as a "strong advocate" for the use of gypsum, and therefore wrote to the advertiser to point out to me any passage in Sir John's writings which might relate to the subject. He obligingly referred me to the 'Farmer's Magazine' for 1843, p. 143, where he states

there is some allusion made to Sir John Herschel's discourse on "Natural Philosophy." As I have not any opportunity of consulting the "Farmers' Magazine," I wrote to Sir John Herschel himself, and have this morning received the following reply:—"I never gave any opinion of the kind you mention, about guano, gypsum, or dunghills. I have said in the *Gardeners' Chronicle* that gypsum does fix ammonia; but I never tried the experiment, and have even some small doubt of the fact that carbonate of ammonia, in a liquid or vapourous state, will decompose solid crystallised sulphate of lime, though I do not deny that it may." Those persons who like myself are anxious to see practical men concentrating their efforts for ascertaining the modes of applying science to practice, in that only way which can be very certain of saving them much time, trouble, and expense, have quite enough of prejudice, ignorance, and apathy to contend against without having their opinions misstated, and their proposals *perverted in a way* which may induce practical men to fancy that science is in error whenever the results promised them by manure merchants fall upon their making trials of their merchandise. I lately noticed a communication from one of your anonymous correspondents, complaining of his having been misled in some way or other by "march-of-intellect men." I see he has since asserted that his remark was not intended as a sneer, but as a caution. I readily offer him the right hand of fellowship in maintaining that sentiment. I am a humble admirer of all "march-of-intellect men," though I belong myself to no other than the awkward squad of their army. Whilst it has been my endeavour to point out to agriculturists the advantages which must follow from their listening to the suggestions of our scientific leaders, I have constantly insisted, in language as plain as I can command words to express myself, on the absolute necessity of caution, on the exceeding absurdity of costly experiments, and on the great facilities they have in their power for working a correct, secure, and rapid method of arriving at legitimate conclusions.

Possessing a hearty desire to see the most important interest in the kingdom improving and flourishing, I feel very unwilling that any little exertions I may have considered myself sufficiently qualified to make in favour of that interest, nullified by misapprehensions and misstatements of my own recommendations. This desire inclines me further to allude to a statement which possibly some of your agricultural readers may have lately noticed either in the *Times* or its adjunct the *St. James's Chronicle*. I may possibly be influenced by other motives as well as the one which I have assigned, but I shall crave your indulgence in introducing the subject here, because I think the effort which has been made to characterise me as a fool, may have some influence in preventing practical men from attending to any future suggestions I may offer them for the application of science to agriculture. A reporter of the *Times* has chosen to say that I have recommended "fireworks as a mode of suppressing incendiarism in Suffolk!" Certainly if I had done anything so foolish, I should not deserve the slightest attention from practical men to any suggestions I may in future make to them. The facts are as follow:—There is in London a Society, called the Labourers' Friend Society, which has effected much good in some counties, by the introduction of allotments, and by various suggestions for benefiting the labourer. A few months ago it was publicly announced in our local papers that it was in contemplation to establish a similar Society in the west division of Suffolk. By way of inviting attention to a variety of topics connected with methods already adopted in different places for assisting the poor, I determined to write a letter weekly in the papers until the meeting preliminary to the formation of the Society should take place. The subjects treated in these letters have been successively—Village Ploughing-matches; Loan Libraries; Coal Clubs; Allotments; Medical Clubs; Official Charities; Benefit Clubs; Recreations for the people. In alluding to the last of these subjects I noticed a plan which has been pursued in my own village for the last seven years, of having a little annual exhibition, for the amusement of the parish, chiefly with fireworks. In recommending something of this sort as a means of restoring periodic returns of amusement to the people, of which there are now very few or none of a creditable character in this part of Suffolk, I proceeded to explain the great facility with which any country family, taking delight in offering recreation and amusement to their neighbours, might prepare such an exhibition in a way that was comparatively inexpensive, and little troublesome. Why this reporter has chosen to say my object was to propose fireworks as an antidote to incendiarism, I shall leave to the suggestions of his own conscience. Any one is welcome to consider me a fool for recommending fireworks or any other works, as a means of amusing our country folks. Such kind of folly is not incompatible with a power of giving advice on the subject of the application of science to practice; but the supposing it possible that I could give such advice as this reporter has strangely ascribed to me, would necessarily be accompanied with a degree of incredulity concerning my capability of giving good advice on any subject whatever, beyond that of squibs and crackers. As for incendiarism in Suffolk, I have publicly stated my opinion on that subject, in a pamphlet I published last August. I believe the crime originated more immediately from the want of employment among a large number of the poor; and I have not yet heard anything to shake that conviction. Why the people are less employed now than they were three or four years ago, is a question which I am not called upon to discuss; but whether they may happen to be sufficiently employed or not, those particular methods to which I have referred are equally adapted to assisting, comforting, or amusing them. I have never proposed either one or all of them together, as substitutes for a want of sufficient employment, or as panacea against any of the evil consequences likely to result from a want of sufficient employment.—*J. S. Henslow, Hitcham.*

Home Correspondence.

Dressing Wheat.—I think, perhaps, the inclosed receipt for dressing Wheat will be acceptable to many of your readers at the present season; its simplicity must recommend it, and I assure you it is a certain remedy against smut:—Shoot a sack of Wheat upon a good brick floor, and place upon it a pailful of boiling water; put a double handful of new lime into the water, and let it remain a few seconds till the water is well impregnated, and then quench it with a quart of urine, or salt water that will carry a new laid egg; pour it over the Wheat, and let two persons stir it well, taking care that every grain is made wet; it will be ready to drill in two hours. The water should boil and the lime be new in lumps.—*A Norfolk Farmer, Fordham, Downham Market.*

Way to Store Cabbages.—Your correspondent "Querist" wants to know the best way of preserving Cabbages in winter. I have little to communicate on the subject; but to what I have, if of any use to him, he is welcome. I have been informed that Drumhead Cabbages are preserved in some parts of Oxfordshire in a way somewhat similar to that of storing Potatoes out of doors. The Cabbages are taken up on a dry day and the stem and loose leaves taken off; they are then put in heaps in a manner like cast-iron bullets in an arsenal, broad at the bottom and narrow at the top; afterwards they are covered with earth. Some years ago I tried to preserve a few barrowfuls of early York Cabbages in winter; I stored them in an outhouse in two lots; one lot was covered with sand, and the other with sawdust; it was done in October. I examined them about the beginning of January, and found that the rats had nearly destroyed them all; the few that remained had the outside leaves rotten, but the heart was good.—*Peter Mackenzie.*——[To this we add the following from a correspondent]—Dig a pit in a dry place, say ten feet long and five or six deep; put in a little dry straw at the bottom; then place your Cabbages (first depriving them of any decayed leaves) on it; put a little dry earth over them, another row of the Cabbages, more earth, and so on till the pit is full; then cover them with dry reeds or Ferns, and put the earth that has been dug out of the pit over them in the shape of a roof, beating it down well, so as to exclude the air and heat: in this way I have found Cabbages to last me till new ones came in, and much longer.—*J. B. Warren, Crookston.*——In addition to this, *R. G.* says:—About two years ago I was staying with a friend, whose gardener was then about storing his Cabbages, of the large drum-head kind. He cut them off, turned them down, and let them drain for a day or two; then marked out a spot, on which he placed a few Pea-sticks. On these he placed the Cabbages, with their heads down; then a few more sticks, or Pea-haulm, for the next tier, and so on, just as you may have seen cannon-balls piled. Outside he put a little straw or slight thatch, just sufficient to throw off the wet, and to allow a good circulation of air. In this way, he assured me, he would keep them till March or April for the family use.

Hedgerows, &c.—Having read with much interest in your Paper, "Notes of a Journey through Southern and Western England," by a Strathern Farmer, I beg to submit a few remarks. Every agriculturist of the present day cannot but deplore the very low ebb of farming in those parts of England which your correspondent has alluded to. Look at Sussex, where a considerable portion of the soil is good, and under a favourable climate, and contrast it with the high lands of Scotland, where the bounties of nature are scarce. But there, in respect to the system of cultivation, they are far in advance of what they are in the south of England, where the country is cumbered with slovenly hedgerows, large brakes and covers, and useless trees, with which the land is surrounded in small patches; their system of ploughing is generally with three horses in a line, with a plough as rude as in the days of Pharaoh, walking in the furrows, while it is well known that if two are yoked properly abreast they will have more power than three in a direct line, besides the injury they do to the subsoil by constantly treading it down. From my early experience in farming under disadvantageous circumstances, so far as regards soil and climate, I do not hesitate to say that if England was cultivated the same as Scotland, the land is capable of yielding double the increase. To obtain this desirable end a new system must be adopted—one that would not only give employment to the labouring class, but provide an abundant supply of food for an increasing population; which certainly must be preferable to sending the surplus population to a distant land, or having a dependence on a foreign country for a supply of food, whilst our own land is uncultivated.—*Alex. Russell, TurnhamGreen.*—I agree with Mr. Grant of Exeter, and a correspondent in your *Chronicle*, regarding the waste of lands by hedgerows; the impoverishing the ground by trees and thorns planted in them; their being a harbour for weeds (with slovenly and bad farmers); the cost of keeping them in repair; and, as in some of the provinces, their being allowed to run so high round small fields, that, owing to the scarcity of light and air, by them a great deal of the crop is robbed of its light, and natural food. Yet, on the other hand, in cold and bleak districts the warm hedge has its advantages; the horse, cow, and sheep are sensible of the protection it affords them from storm as well as sunshine. Moreover, I am old enough to have a lively remembrance of Napoleon's intended invasion of this country, and how many writers then looked to the hedges of England as formidable bulwarks against an enemy. But, apart from hedges in a warlike point of view, how *triste* the land would picture to the eye of such men as a Goldsmith or a Wilson with immeasurable plains without a break! What would become of the merry singing warblers from hedgerows? Their destruction, perhaps, many a farmer thinks would be reason enough to have the hedges down. But whether are birds friends or enemies to the farmer?—there is wide opinion conderning the general harm or good they do.—*Lt.*

Failure of Potatoes.—As the cause of the failure of the sets, when planted, is still involved in much obscurity, I mention the following circumstance:—One of my neighbours planted a ridge this year, with the kind called here Prolifics; the sets were all cut at the same time, and from the same sample; part was planted in the afternoon of one day, and the remainder next morning. The first all grew, and of those planted the next day, nearly all failed. The state of the land in each case was perfectly similar; the weather had been dry, and no rain had fallen in the interval. The circumstance is curious, and to me perfectly inexplicable. Can any of your correspondents account for it?—*Lusor.*

New and Old Land.—In answer to "Paddy," in your last Number, I see no conflict between the prevailing theory of the day and the practice stated in an extract from Cobbett's "English Gardener," because Peas in a garden are invariably set at considerable intervals; and if care be taken, they may be planted on the same border annually on a fallow of three years' standing. Had the Peas been sown broadcast for 15 years, Cobbett would have had to tell a very different tale.—*W. C.*

Flax-seed.—Having perused with interest the Articles by Mr. Sproule upon the cultivation of Flax, and also the details given as to the uses of Flax-seed as a food for cattle, as practised by Mr. Warnes, I venture to ask that gentleman to favour us with a little further information as to his mode of preparing Flax-seed before making it into jelly. Mr. Sproule seems to speak as if a common corn-crushing machine was sufficient for grinding it before it is boiled into jelly; now, I have myself tried this method, and made good thick jelly, but could not satisfy myself that its effect in fattening cattle was at all equal to that of the common oil-cake. The failure in my own case may have arisen from the seed having been insufficiently crushed, and a portion of it passing through the animals without being digested. Is it possible to grind Flax-seed in a common grist-mill, so as to make linseed meal; or would the oil be thereby expressed? The supply of good nutritious winter food at the cheapest price, is at the present moment a subject of such paramount interest to most farmers, that I make no apology for intruding it upon your columns.—*A Gloucestershire Subscriber.*

Fire-clay as a Manure.—While on a visit at the residence of Thomas Sprot Esq., Garnkirk, near Glasgow along with two or three other gentlemen whose names will be furnished, if desired, I had the gratification of testing the result of an experiment made between the fertilising properties of stable-dung and fire-clay, which I have no doubt will prove of interest to your horticultural as well as agricultural readers. In the month of April last, Mr. Sprot selected four Potatoes, of the kind called in that quarter Red Droppers, of medium and all of an equal size, which he planted whole. Two of these he planted with a large spadeful of well rotted hotbed stable dung well incorporated with the soil. The two other he planted alongside of the above, and about 18 inches apart from them, incorporating with the soil about an English plut of the Garnkirk fire-clay, ground to powder. The chemical constituents of this clay, which is dug from a depth of about 20 fathoms, as tested by Professor Thomson of Glasgow, are given below. The whole four Potatoes came away, and those grown with the dung at first took the lead; but in a short time those grown in the fire-clay gained upon and got in advance of the others, exhibiting broader and more luxuriant foliage. On 30th September, when the produce was taken up, the stalks of the dunged Potatoes were quite dry and decayed, while those in the fire-clay were green and but slightly faded in the leaf, and might thus have grown for some little time longer. These are the results:—

Those in hotbed dung:—

No. I.	.	25	Potatoes	. 2 lbs. weight.
No. II.	.	21	"	. 4 "

Those in fire-clay—

No. I.	.	28	"	. 6½ "
No. II.	.	23	"	. 8½ "

Thus the fire-clay produced in both shaws not only about double the weight produced by the dung, but the Potatoes were larger and finer in appearance. Four of the fire-clay ones were boiled and found to be of excellent quality, mealy, and finely flavoured.

Transmutation of Species—Curiosity in Corn.—What we may call a natural curiosity was brought to our office by Thomas J. Biggs, Esq., of Garryhinch, Kedmore on Saturday. It was an ear of Wheat, with

grain of Oats regularly formed and full, growing out of each side. The ear was picked up at Shippool, the residence of Captain Herrick.—*Cork Can.* As a proof of the correctness of Lord Bristol's experiment on Barley, mentioned in one of your late Papers, I send you the above paragraph, taken from a Cork paper, which most probably you may not have seen.—*E. F. L.*

FARMERS' CLUBS.

Inverness.—The following are extracts from a communication by R. Grant, Esq., of Kincorth, on the interesting subject of Reclaiming Sand-hillocks and Beaches by Plantations of Scotch Fir and Larch. We are indebted for them to the *Inverness Agriculturist*, in the columns of which the letter was placed by Mr. Anderson, Secretary to the local Farmers' Club of that district, to whom it was addressed:—"Were my accounts to be exhibited, I do not believe they would entitle me to the praise of an economical planter; but my object is rather to describe what I consider I may now deem a successful attempt to clothe pure sand hills with thriving plantations of Scotch and Larch Firs. The ground planted is situated in the outskirts of the well-known tract of the Sand Hills of Coubin, which are so conspicuous along the seacoast, to the northward of Forres. My residence being in the immediate vicinity of that dreary waste, I long felt an anxious but hopeless desire to adopt any probable means by which the barren appearance of the neighbourhood might be improved; but for years I could not bring my mind to cherish a hope, notwithstanding the repeated recommendations of friends to plant, that trees would grow on so sterile a soil; and it was not until 1836 that I at length resolved to make the experiment. The whole plantation covers an extent of about 70 acres, in the form of a belt, extending about a mile in length, and varying from 100 to 400 yards in breadth. Some portions of the ground consist of a flat sandy moor, intermixed with small quantities of Moss, which, when planted, was covered with some coarse Grass and stinted Heather. In other places the soil is of a black gravelly nature. And, with respect to these two divisions of the plantation, there is nothing of peculiar interest to detail, or remarkable in the growth of the plants; and I shall only allude to them as exhibiting the comparative growth of plants under ordinary circumstances, with that of the trees planted in the sand hills, which extend over the remainder of the plantation. Of these sand hills, or more properly hillocks, I may state that they are of that description the appearance of which must be familiar to every one who is acquainted with the sandy coasts of the country: they vary in shape in every possible way, and in height from 10 to 30 or 40 feet. With respect to the herbage upon them at the time when they were planted, they may be divided into three classes: 1st, Those most recently formed from sand-drift, on which Bent alone, and that but partially, grew—quite clean and open about the roots, as Corn in a well-cleaned fallow field; 2d, Those where the Bent, having been protected for years, had rotted, and the ground being afterwards pastured by sheep and cattle, a thick sward of Grass had grown up in its stead; 3d, Those which were in a still more advanced state from their original formation—the grassy sward or crust upon them being supplanted with Whins and Broom. The planting was commenced in the spring of 1837, and was continued annually, in portions of from 15 to 20 acres, until the whole was finished. The plants were of the common description of Larch and Scotch Fir—the latter grown from seed procured from the forests of Strathspey. They were raised by Mr. Grigor, nurseryman at Forres, in his nursery there; and before being planted they were not removed from their native nursery ground to any intermediate description of soil, to prepare them for transplantation to the sand-hills. The plants first used were very small, being one-year-old transplanted seedlings; and these throve remarkably well in the moorish ground, and also in the Bent hills, where the moisture easily got access to the roots of the plants. In the grassy parts, however, most of the small plants withered, from want of sufficient moisture, or from being choked by the Grass; and I afterwards found that larger-sized plants succeeded better in such ground, which I conceive arose from their having more sap within themselves, which enabled them to resist the drought longer, and until vegetation commenced. With respect, indeed, to these arid grassy parts of the plantation, I cannot report that I have been as yet, notwithstanding repeated planting of the ground, very successful in establishing a sufficient quantity of healthy plants in the soil; and I must confess the waste of plants and labour in these parts has been very great. In the moor ground and soft open sand, the planting was executed by women, with small iron dibbles, which mode I found perfectly successful. In the second planting in the grassy places, I employed men to plant with spades, who pared the surface before putting in the plant; and this plan I have found attended with more success, although considerably more expensive. I have already stated that Whins and Broom covered certain portions of the ground; these before planting were cut, and allowed to remain on the ground, and have sheltered the young plants, which have generally thriven pretty well in such places. Before concluding this short statement, I may mention that some parts of the ground were planted in November and December, and others in the spring months. I have little hesitation in saying, from my experience, that winter planting should always be adopted in preference in such dry sandy ground, as the winter rain invigorates the plant, and enables it to outlive the summer drought. I must repeat that the expenses of the work exceeded the ordinary outlay upon such improvements—partly occasioned by the great destruction of plants during the first two years by rabbits, which infested the ground in great numbers, and which I had not taken the precaution to have destroyed; and an extra expense was also incurred by the cleaning of those parts of the ground which were covered with Whins. But this is the first experiment, so far as I know, which has hitherto been made in Scotland of planting sand-hills, and my success has been such as I think warrants me in holding out encouragement to proprietors who may possess similar ground along the flat, bleak, wild, and profitless coasts of our country, and who may be anxious to change their barren aspect. The most advanced part of my plantation is now seven years old, and I gladly invite any who may feel an interest in the subject to visit the place, and witness the healthy and vigorous condition of the plants at their present age. It is impossible, indeed, to predict what height or size trees may ultimately attain in such soil. I am far from expecting that timber of any great size will ever be procured, although I am sanguine that trees which may be useful for many country purposes will grow on it; but I think I may safely assert that, in the great object I had in view, I have every prospect in due time of perfectly succeeding, viz., in rendering what was an unsightly desert in some measure ornamental."

Stow-on-the-Wold.—The meeting of this Society was held on Friday week. Mr. Newberry's dibbling-machine was the subject of not a little conversation during the day. It was related that Mr. Harris, of Upper Swell, had threshed out an acre of drilled Wheat, and an acre dibbled by Newberry's machine; on the drilled acre was sown six pecks of seed, and on the dibbled five pecks; the drilled produced 26 bushels, and the dibbled 33 bushels and a half; the dibbled Wheat was heavier by a pound a bushel than the drilled—making altogether a produce of upwards of 30 per cent. available for the market, in favour of the dibbling-machine.

Reviews.

The Report on the Agriculture of Norfolk, to which the Prize was awarded by the Royal Agricultural Society of England. By Richard Noverre Bacon. London: Ridgway, Piccadilly.

THE diffusion among farmers generally of what is already known and practised by the few of them in our best cultivated districts, is in all probability the most efficient method of improving British Agriculture. More good will probably be done thus, and with greater economy too, than by increasing the number or encouraging the industry of the numerous labourers now working on the junction lines of agriculture with the sciences by which it is surrounded. Do not let us be thought to undervalue the labours of the chemist or geologist; the farmer has of late become deeply indebted to scientific men for important suggestions and explanations of practice. There is still, no doubt, room for great improvements in our best systems of farming—improvements which have been, and probably will continue to be indicated by scientific men; but there is such a great difference between the practice of those who farm well, and that of the many below them on the scale of excellence, that great national good would undoubtedly arise from an improvement in the management of the latter class, though that of the former should for a long time remain stationary.

If we could find as superintendents, men uniting a perfect knowledge of the system to be promulgated, with a capability of duly estimating the influence of the peculiarities, as regards soil, climate, &c., of the districts in which they would be stationed, then the establishment of example farms would undoubtedly be the best method of effecting this improvement. But few, if any, such farms are now in existence, and in their absence we must therefore look to the assistance of the press, and hope for success in the efforts now making to set before the agricultural world the modes and results of the practice of good farming.

The late Board of Agriculture appear to have been fully impressed with the importance of this kind of publication, and they accordingly addressed themselves to the task of collecting agricultural reports of all the counties in Great Britain; and a series of volumes was the result, which contain a vast mass of useful information. The English Agricultural Society, after the lapse of 30 or 40 years, are adopting a similar plan, and several county reports have lately been published in their journal. The volume before us is the report of Norfolk, to which their prize was awarded. It was too voluminous a production to appear in their Journal; but, comparing it with those which have already appeared in that periodical, as it enters into greater detail than any of them, and as it describes a district which has been long celebrated for its agriculture, we hope it will not on that account be the less extensively read and known.

We shall take another opportunity of directing the attention of our readers to it, more closely and at greater length, simply stating at present that its contents are very interesting and instructive; and that the authorities given for its accuracy are both numerous and unexceptionable.

The Police and Constabulary List. Parker, Furnival, and Parker, Military Library, Whitehall, London.

THIS is one of a quarterly periodical (for the quarter ending September, 1844), intended to present in tabular forms the arrangement and nature of the police force employed in the metropolis, the counties, and provincial towns of Great Britain, together with details of the nature and amount of crime in the several districts in which they are stationed. The aggregate of all these subordinate statements for the quarter is represented in a well-arranged Table at the commencement of the volume; the number and character of the various instances of offence, within the period, being given for each of the several main districts, such as agricultural, manufacturing, and maritime, into which the author has divided the country. Besides the technical and professional usefulness of such a publication, so well-arranged a statement of the condition of a country in one of its most important aspects, must be of great value in the eyes of all those interested in the statistics of crime.

Miscellaneous.

Cure for the Distemper in Cattle.—I cannot resist giving a receipt for the treatment of beasts that may take the prevalent distemper. It showed itself last winter in one of my yard stock, by its discharging abundant saliva from the mouth, with sore and inflamed tongue and gums, very dull, no appetite, confined bowels, and very hot horns. I desired the bailiff to give him one half-pint of the spirit of turpentine, with one pint linseed oil, repeating the oil in twenty-four hours, and again repeating it according to the state of the evacuations. At the end of twenty-four hours more, the bowels not having been well moved, I repeated both turpentine and oil. In two days the beast showed symptoms of amendment, and in three or four took to his food again, and did perfectly well. All the yard beasts and two of the fattening beasts have had it (five others I had sent to London before the disease appeared), and all have been treated in the same manner with perfect success. Half-a-pint of turpentine is the smallest, and one pint the largest dose during three or four days. Little food beside Oatmeal gruel was given.—*Quarterly Journal of Agriculture.* [The remedy above prescribed has been found effectual in this neighbourhood in several cases, even where the disease had attained a considerable height. It was tried with success by a farmer near Donnemana, and many of his neighbours whose cattle had taken the distemper.—*Londonderry Sentinel.*]

Report of the Thorough-Draining executed on the Estate of Edward Lucas, Esq., Castle Shane, Monaghan, by Fitzherbert Filgate, Esq.—The small drains are dug 32 inches deep, 5 inches wide at bottom, 7 at top of stones, and 16 at top of drain; 14 inches in depth of stones, which are covered with a Grass sod, about an inch in thickness, the Grassy side downwards; the remaining 17 inches filled with the earth cast out in cutting the drains. The width at bottom, 5 inches, is greater than is generally to be recommended; but I was prevented cutting them as narrow as I could wish, from the slaty nature of the stones of the neighbourhood, which does not admit of their being broken small; as, if reduced below a certain size, they fly into a hundred pieces. The stones being large, the drains were made wider on that account; and, although I would never recommend the practice where stones which would break cubically could be procured, one advantage is derived, namely, the possibility of cutting your drains with the spade in common use in the North of Ireland. In that case the only implement required exclusively for draining purposes, is the scoop or shovel for cleaning out the bottom of the drain. After the scoop is used, I have the bottom of the drain swept down with a broom; and the stones having been first carefully riddled, are immediately put into the drain: thus, as far as possible, guarding against mud and dirt, either lying in the bottom of the drain, or being introduced into it along with the stones. I consider that the sooner the drain is filled after being opened the better, particularly in frosty weather succeeded by rain, such as we frequently have in the early part of winter. If this be not attended to, much waste of labour and stones arises, and each cleaning out the drain, of course, enlarges it. Should delay in filling be unavoidable, it is prudent to stop up the mouth of the drain with straw, when communicating with other drains, and so prevent a run of sand or sediment into them. I never run the parallel drains into an open main drain; because, the mouths of these drains are sure to be stopped by grass growing at them, by frogs or rats running up them, by cattle tramping, and by the stones slipping, if the drains are on a steep inclination. The expense of main drains is, no doubt, considerable; but Mr. Smith, of Deanston, having mentioned that main drains, filled with broken stones, were equally effectual with those flagged or arched, I was induced to try the experiment, and have every reason to be perfectly satisfied with the result. The difference in expense is very considerable, amounting in my case to 2*d.* per perch for cutting and breaking stones; and the difference in the quantity of stones used is immense; 6½ cwt. of broken stones suffice, when 14½ cwt. is required for flagging. The small drains are all made 18 feet apart. The main drains were, for the most part, flagged—made 38 inches deep, that is, 6 inches deeper than the small drains; the open or swallow being 6 inches wide and 8 deep. Some of the later main drains were filled with broken stones, about 4 inches in diameter; these drains were also 38 inches deep, 9 inches wide at bottom, with 21 inches deep of stones. None of the main drains are of less dimensions than those given above, and some are considerably greater. It is, of course, understood that the depth to which it may be necessary to sink a main drain, for the purpose of procuring a proper fall, will depend upon the nature of the ground; the dimensions given are those supposed to be necessary in the most favourable cases. Iron gratings, like guidirons, are placed at the mouths of the main drains, to prevent the ingress of rats or frogs; and such a precaution is most necessary, as myriads of the latter especially will ascend and choke the drains, as may be easily ascertained by opening one

some time made. I may add that the stones are laid alongside the intended drain before the cutting has been commenced. Early in 1842 I commenced upon the field containing 13a. 1r. 5p. It is a field of strong clay, generally 16 inches deep, upon an almost impervious subsoil of white till mixed with small stones, so hard, that the pick was required in every inch. The main drain crossing a part of the field, runs in a hollow, and was necessary from the nature of the ground. The prices paid for executing the different works in this field were higher considerably than those since paid; as it was only the second field that had been attempted here, the people in the neighbourhood were unaccustomed to the work, and could not calculate the value of their labour by the perch; nor from want of experience in the former works, could they earn as much, perhaps, as they since have done at lower rates. The field lies on the side of a very steep hill, which made the drawing of stones difficult. In this case two contracts were made: one for cutting the drains, breaking the stones, sodding and filling the drains, at 3½d. per perch of small, and 7½d. for main drains; another for quarrying in an adjoining field on the demesne, drawing and laying down stones alongside of drains, at 4½d. per perch of small, and 8½d. per perch of main drains. The account of this field therefore stands thus—

No. of acres in field.	No. of perches of small drains	Price per perch.	No. of perches of main drains.	Price per perch.	Total cost of field.	Cost per acre.
A. R. P.		s. d.		s. d.	£. s. d.	£. s. d.
13 1 5	2347	0 8½	1972	1 4½	92 16 ½	6 1 0

This field was broken up after being drained, and sown with Oats, which turned out a very heavy crop, averaging 150 stones per acre. It was then deep ploughed, and is this year (1843) part in Potatoes, part in Turnips; the former are an excellent crop, producing 14 tons 7½ cwt. per acre; the latter middling, having run very much to top, which I attribute partly to the season, and in a great measure to the sheltered situation of the field, being nearly surrounded by planting.—*From the Irish Agricultural Society's Report.*—[*To be continued.*]

Lucerne.—Mr. W. Pepper, of Sutton Coldfield, has raised a crop of it for several years. It may be harrowed in with Barley on land that has carried Turnips. It should be covered in October or November with light stable manure; harrowed in the spring to get out the weeds; and deeply harrowed, almost like a fallow, in the autumn. The broadcast he considers better than the drilled. In some seasons he has got twelve tons to the acre: he has seen it run to the height of five feet five inches; its ordinary height is four feet. An acre will keep three strong cart-horses for six months, from 1st of May to October. — *Royal Agricultural Journal*, vol. iii. Parts 2 and 3.

Thick and Thin Sowing.—You think thin Wheat is not more liable to mildew than thick. Now all I have ever seen or experienced proves the contrary; namely, the thin late Wheat is sure to take it if any does, while the thick is frequently not injured at all. I have occupied between 500 and 600 acres of land for upwards of 30 years, and never suffered through having Wheat too thick by sowing but once, and that was last year; but many times through being too thin. Owing to some of my Wheat being so very thick and down last year, and hearing so much of throwing seed away last Wheat seed-time, I thought I would try the thin system on a six-acre piece. I dibbled two acres in the middle at the rate of four pecks per acre, the two acres at each end with eight pecks per acre, the land and all being done just the same; but the result was, I believe I had double the quantity of Wheat where I sowed eight pecks, to what I had where I only sowed four; and where I drilled 12 pecks per acre on other land, I had a much better crop than either of the others. Mine is poor land, and I believe thin sowing will never do for such sort of land; at any rate, I am quite satisfied, and will not again try four pecks per acre if I can help. I confess this is not a good year for thin-sown corn.—*Correspondent of Bell's Weekly Messenger.*

Stifle-burning.—Residing in a district in which stifle-burning is a good deal practised, and having been in the habit of doing a little on my own farm, I will simply state what I consider to be its advantages and its disadvantages. On heavy and tenacious soils its effects are decidedly good, in pulverising the land, making it work more kindly for the succeeding crops. Stifle-burning is usually a preparation for a Turnip crop; in moist seasons they are very good on this plan of management. On thin stone brash land, which is already too light, it must be injurious, as it certainly makes all soils porous; and as this kind is improved by being made firmer, I think it would be better not to burn the earth at all, but only the vegetable matter which works to the surface. This can only be proceeded with in very dry weather; therefore it cannot always be depended on regularly for procuring a crop of Turnips, which the summer of 1843 fully proved: other manures were then resorted to as a substitute. The expense attending it is also a disadvantage; on an average not less than one ton of straw per acre is used, which, added to 10s. per acre for manual labour, makes it more expensive than a moderate dressing of bones, which I consider to be superior. The old system of paring and burning is undoubtedly excellent, as an active manure is produced by burning the turf, couch, &c., without weakening the soil. Although it has been much spoken against, and altogether prohibited by some landed proprietors, farmers on light soils would feel a great loss if denied this privilege of paring and burning. —*A Farmer near Bradford.*—*Bell's Weekly Messenger.*

Notices to Correspondents.

Arrangement of Forest or Trees.—*W. C.*—The highest horse should be foremost, and the next next the implement, the others being ranged forward according to their height. It is much more ornamental to adopt a plan in which, every horse pulling directly on the implement, their arrangement with regard to one another becomes of no consequence. We shall very shortly consider the best way to harvest roots. Your arrangement for draining Potato-pits is good.

Books.—*A. Z.*—We know of no work expressly to afford instruction in the art of fattening prize beasts. See Hillyard's "Practical Farmer and Grazier."

Death of Ewe and Lamb.—*A. B. C.*—Like the Chaldeans of old, we are required not only to state the interpretation of the disease, but to name the disease itself. Not being a second Daniel, we are unable to expound the matter. If it had been mentioned what leaves the ewe and lamb ate, we might have afforded some explanation. A small portion of the leaves of the Yew-tree, particularly if in a withered state, would produce the effect stated.—*W. C. S.*

Food for Young Pigs.—*Cockney.*—Steamed Potatoes and Barley meal, with water, or whey, or skim-milk.

Gardeners' Chronicle.—*B., Scarborough*, can have the volume for 1843 of the *Gardeners' Chronicle*; order it through your bookseller; as, being bound, it cannot pass by the post.

Harvesting Roots.—*W. C.* and *A Young Beginner.*—Please wait till next week and we shall give full information then.

Index.—*A Constant Subscriber, Barnstaple*, will have, at the end of the year, a complete Index. The weekly ones surely very much simplify the task of finding any article.

Lime and Manure.—*H. C. S.*—If you manured this spring, you may, with probably greater advantage (comparing it with the expense), apply 100 bushels of lime *now*, for next year's crop, than apply manure which you say would cost 8*l.* per acre. If it was last year that you manured, you had better apply another coating of manure next spring, and in that case reserve your liming till the year after, or at any rate till the autumn. Generally speaking it is considered better policy to apply lime before a Corn than before a green crop.

Poor-rate Appeal.—*Mailcid.*—The Court of Quarter Sessions or the Justices in Special Sessions, before whom an appeal against a poor-rate is determined, have the power to award, and generally do award costs to be paid by the *unsuccessful* party.—*W.*

Potatoes.—*J. B.*—R. recommends that the Potatoes should be covered with dry earth. They may be laid in pits, or pies, as they are sometimes called, as usual, perhaps a yard wide and a yard high in the middle, then covered with dry earth a spade-blade thick, and then thatched or covered with the Potato leaves or straw. Ground may be rendered dry enough for it by digging a ditch round the pit a foot below the bottom of it.——*R. W.*—By all means try the experiment: plant a few rows of them early in November, fully six inches deep. Plant them whole; whether frost will hurt them or not will be determined by the result you obtain: the object of your experiment will be to ascertain that. From what little evidence exists on the subject, it seems probable that in many districts Potatoes may be planted in autumn with advantage.

Rot in Sheep.—*W. C.*—Salt is unquestionably the best preventive of the rot in sheep; but I believe that the idea that either Alder bushes or the web of the gossamer has any influence in the matter is altogether fallacious. It is not cold land, merely retentive of moisture, that is most apt to rot, but rather rich wet pastures, most susceptible of the influence of the sun, and on which vegetable decomposition readily takes place. Coincidences are very frequently supposed to stand to one another in the relation of cause and effect, and in the case in question they must have led to the supposition that Alder bushes and gossamer webs were preventives of the rot.—*W. C. S.*

Rye.—*R. Hinde.*—Your specimen appears to be that of true Rye. It is impossible, we think, that any such influence as you suggest could have been exerted by the last year's Wheat.

Sulphate of Iron.—*An Original Subscriber.*—Sulphate of iron will not injure the feet of horses nor their clothing, otherwise than staining them of a black colour, if the iron be in solution. —*W. C. S.*

Thistle.—*O. P. Q.*—We have perfect confidence in saying that unremitting perseverance in cutting off these weeds whenever they appear will ultimately kill them. It may take two years to do this—perhaps three; but you have only to choose between this and ploughing up your land, fallowing for a couple of years, and laying it down again.

To Architects.—*A Subscriber of some years' standing*, will be obliged for any effectual method of preparing a new wall so as to receive colouring. At present the fresh lime eats it away as soon as it is put on. If patience alone is wanted, how long will it be, in ordinary circumstances, before the walls are dry without a fire? We apprehend at least twelve months.

Top dressing for Pasture.—*G. M.*—In all probability the application of 20 bushels of fine bone-dust per acre, now, would be highly beneficial.

Variety of Wheat.—*J. D. Piper.*—Your specimen is that of a variety of large-berried Wheat, in very thickly compressed and well filled ears.

*** As usual many communications have been received too late.

Markets.

SMITHFIELD, Monday, Oct. 7.—Per stone of 8 lbs.

Best Scots, Herefords, &c.	3s 8 to 4s 0	Best Downs & Half-breds	3s 8 to 4s 0
Best Short Horns	3 6 3 10	Best Long-wools	3 6 3 10
Second quality Beasts	3 2 3 4	Ewes and second quality	3 0 3 6
Calves	3 0 4 0	Lambs	3 8 4 4
Pigs	3 4 4 0		

Beasts, 4170; Sheep and Lambs, 26,940; Calves, 100; Pigs, 263.

We have a larger supply of Beasts than any day this season, and a great majority of very middling quality; the best descriptions for the most part maintain their prices, although several very good Beasts only make 3s 10d, and Short-horns 3s 6d per 8 lbs; inferior Beef is sold very low—indeed a great deal cannot be sold at all; very many remain unsold. The supply of Sheep continues about the same; the demand is rather increased; on the most selling qualities there is an advance of 2d per 8 lbs since last Monday. Veal trade is excessively heavy, very few indeed make 4s; second quality are very low. Pork-trade is hardly so good.

FRIDAY, Oct. 11.

We have a large supply of middling Beef, which is very unselling, making from 3s 8d to 4s 2d, the best Beasts, &c., about 4s 10d, and Short-horns 3s 6d per 8 lbs. Trade is very heavy indeed, owing to the extreme dullness at the dead markets during the week. There is a fair supply of Sheep for the time of year, the demand being very small; about the same prices as on Monday are obtained, except for Ewes, which are fully 2d per 8 lbs lower. Lamb is now nearly out of the Market, and we shall cease to quote it; it now makes no more than Mutton. Veal trade is very bad; the best Calves scarcely make 4s, and many of second quality are sold at from 3s to 3s 6d. Pork is a little better.

Beasts, 771; Sheep, 8880; Calves, 841; Pigs, 870.

dl, West Smithfield.

POTATOES.—Southwark Waterside, Oct. 7.

Several cargoes of Cornish Reds arrived during the past week, which were opened at 70s. but at the close 65s was submitted to. There being only one cargo of Scotch Reds in the Market they realised 70s. The York Reds have not yet made their appearance.

COVENT GARDEN, October 12.—The continuance of fine weather has caused very large supplies of everything in season to be brought into the market; but trade is far from being brisk. The remarks on Pine-apples made last week apply equally to the present. Hothouse Grapes, both Black and White, are abundant; Portugals are a little dearer. Peaches are becoming very scarce and are considerably advanced in price. Plums are also getting scarce and dear. Damsons are, however, tolerably well supplied, and have not altered in price since last week. Apples and Pears are offered at the same prices as quoted in our last report; they are good in quality and are very abundantly supplied. A considerable quantity of bitter Oranges are yet in the market—the best are offered at about 20s. per 100. Large supplies of Walnuts have been brought during the week—they bring from 4s. to 5s. per bushel. Shelled Walnuts are also plentiful. We noticed a good dish of Keen's Seedling Strawberry. Among vegetables Cauliflower continues to be pretty well supplied; and Broccoli of good quality is sufficient for the demand. Brussels Sprouts have not altered in price during the week. A few Peas are still offered, but they are now nearly over for a season. French Beans, although scarce, are good in quality—they bring from 2s. 6d. to 3s. 6d. per half sieve. Artichokes are very scarce. Of Carrots and Turnips there are plenty; and Cabbages are quite sufficient for the demand. Some good samples of Savoys have just made their appearance in the market. Of Celery the red sort is plentiful, but the white is rather scarce—both kinds are excellent in quality. Lettuces, Endive, and most other kinds of salading, are abundant. Cut flowers chiefly consist of Achimenes coccinea, Phlox Drummondii, Erythina crista-galli, Gladiolus psittacinus, scarlet Pelargoniums, Verbenas, Heathe, Camellias, Fuchsias, Amaryllises, Carnations, and Roses.

FRUITS.

Carrots, per doz. bchs., 2s to 6s	Small Salads, per pannet, 2d to 3d
Basil, per bunch, 2d to 3d	Watercress, p. 12 sm. bun., 3d to 6d
Horse Radish, per bundle, 2s to 3s	Parsley, per doz. bunches, 1s to 2s
Savory, per bunch, 2d to 3d	Tarragon, Green, per bunch, 3d to 6d
Cucumbers, Frame, each, 3d to 9d	Green Mint, per bunch, 2d to 3d
— Ridge, doz., 2d to 2s 6d	Marjoram, per bunch, 2d to 3d
Vegetable Marrow, p. doz., 1s to 1s 6d	Chervil, per pannet, 2d to 3d
Spinach, per sieve, 1s 6d to 2s	Chilis, per 100, 1s 6d to 2s

HOPS, Friday, Oct. 11.

The Market continues to advance for all good Hops. Duty, 130,000*l.*

Fairbairns & Harris, Hop-Factors.

MARK-LANE, Monday, Oct. 7.

The supply of English Wheat from the adjacent counties was again moderate this morning; fine samples, being scarce, sold readily at the terms of this day week, but secondary qualities are difficult to quit at a reduction of 1s. to 2s. per qr. The demand for Foreign was limited, but its value is fully supported, particularly of fine descriptions.—Barley is firm at our quotations.—Beans and White Peas are unaltered in value, but Maple in some instances command a trifling advance.—The supply of Irish Oats is large, and consists principally of New, for which the late terms are unwillingly complied with; Old and Foreign are firm at last week's prices.

Foreign . — — 280 —	740	1344	—	2402	—	—	—

FRIDAY, Oct. 11.

The arrivals of all Corn during the week have been moderate, and the Market since Monday was thinly attended; Wheat, either English or Foreign, has met a very limited inquiry; the former may be purchased on rather lower terms, but the value of the latter is maintained.—Canada Flour sells slowly at 28s. to 28s. per barrel.—In Barley, Beans, and Peas we observe no alteration, but the prices of the two first articles have rather a tendency to advance.—In Oats a fair business has been done, and they are held firmly for Monday's quotations.

ARRIVALS THIS WEEK.

NEW PHLOXGONIUMS, to be sent out by N. GAINES, the first week in November. Queen's Daughter 3l. 3s.; Leinster 3l. 3s.; King of the Belgians 2l. 2s.; Trafalgar 2l. 2s.; Miss Hawthorn 2l. 2s.; King of Saxony 2l. 2s.; Sir W. Massey Stanley 2l. 2s.; Marchioness of Lorn 2l. 2s.; King of the French 2l. 2s. With many first-rate Seedlings raised by their Originators; of which a printed Catalogue may be had the latter end of the month.—Surrey Lane, Battersea, 9th October.

CHAPMAN'S KIDNEY POTATOES.—CHARLES and THOMAS CHAPMAN, of Brentford End, Isleworth, having been obliged to disappoint numerous applicants for their Potato, beg to say that they will execute orders at the taking up at 10s. per bushel; and that persons may see the quality and the yield by attending at the time; they will also give instructions how to keep them, and plant them at the proper season.—Brentford End, October 11, 1844.

FOR FRAMES, GREENHOUSES, &c.

JOHN HAYES, respectfully offers his Composition for rendering Brown Holland, Calico, and Irish Linen Transparent and Waterproof. His own Greenhouse is covered with cloth prepared with this Composition, and answers admirably; the cloth requiring only a coat of boiled oil once a year to render it as lasting as the wood frames; and the plants, which require only half the usual quantity of water, are more vigorous and healthy than under glass.

Specimens of the prepared Cloth may be seen at Messrs. BATT and BUNLEY'S, 412, Strand; of whom, or at his Nursery, West street, Fareham, Surrey, the Composition may be had, at 2s. 2d. the quart bottle, sufficient for 100 feet of cloth.

WANTED, a GREENHOUSE, immediately, for a Private Garden; a substantially-built, second-hand House, in a good state of repair, from 16 to 20 feet long, by 12 to 14 feet wide.—Apply, by letter only, to Mr. SAYMAN, Builder, Wandsworth, with particulars of size and price.

BOG EARTH and LOAM for PLANTS.—Good rotten Bog Earth and Mellow Sandy Loam, in excellent condition for potting, &c. (having been dug four years since), may be had by applying to B. BURT, Wimbledon, Surrey. Cartage according to distance.

SLATE WORKS, ISLEWORTH, MIDDLESEX.

THE following Articles, manufactured in Slate for Horticultural purposes, may be seen in use at Worton Cottage, upon application to the gardener (Sundays excepted).

Tank Covers	Bottoms for Frames
Cisterns	Boxes for Balconies and Verandahs
Shelves	
Garden Edging	Orange Tubs, Flower Boxes, &c.

EDWARD BECK will be happy to answer any inquiries, either personally or by post.

Sales by Auction.

SIX DAYS' SALE OF VALUABLE NURSERY STOCK.

MESSRS. PROTHEROE & MORRIS will submit to Public Competition, by Auction, at the American Nursery, Leytonstone, Essex (about one mile from the Railway Station, Stratford), on Monday, 21st October, 1844, and five following days, at 11 o'clock, (to close Executors' accounts), the celebrated NURSERY STOCK, consisting of the choicest kinds of Fruit and Forest Trees, fine Evergreens, Ornamental, Deciduous, and American Plants, of every variety, in considerable quantities, and lotted to suit every description of purchasers. The Stock is particularly worthy the attention of Noblemen and Gentlemen laying out their grounds, from its having many rare specimens that are only to be found in first-rate collections (also of the Trade, from its excellence), and comprising several thousands Azaleas, Rhododendrons, Ledums, Andromeda, all in fine condition for potting, being well furnished with bloom buds.

N.B. The ground is proverbial for safety of removal, the mould adhering to the roots. May be viewed prior to the Sale. Catalogues, One Shilling each, returnable to purchasers, may be had of the principal Seedsmen in London, at the Auction Mart, and of the Auctioneers, Leytonstone, Essex.

ISLINGTON NURSERY.

TO NOBLEMEN, GENTLEMEN, NURSERYMEN, and Others.

MESSRS. PROTHEROE AND MORRIS are instructed by the Proprietor to submit to Public Competition, on MONDAY, 14th October, 1844, and 2 following days, at 11 o'clock, (in consequence of the ground being required for building,) a portion of the valuable NURSERY STOCK, consisting of about five thousand Belgian Azaleas, in 40 fine varieties; several thousands fine Hybrid Rhododendrons, well furnished with bloom buds; Green and Var. Hollies, Chinese and Siberian Arborvitæ, about five thousand Laurels, with a fine assortment of Fruit and Forest Trees, Flowering Shrubs, &c.

May be viewed prior to the Sale. Catalogues may be had on the Premises; of the principal Seedsmen; and of the Auctioneers, American Nursery, Leytonstone.

TO GENTLEMEN, FLORISTS, AND OTHERS.

MESSRS. PROTHEROE AND MORRIS are instructed by Mr. FRANKLIN (in consequence of his Lease having expired and the ground let for building) to submit to Public Competition, on the Premises, Cottage-place, City Road, on THURSDAY, October 17th, 1844, at 11 o'clock, the whole of his VALUABLE STOCK, consisting of named Seedling Tulips, Auriculas, Carnations, Picotees, and Phlox, Greenhouse and Herbaceous Plants; a capital Greenhouse, 28 ft. by 11 ft.; and sundry Effects. May be viewed prior to sale. Catalogues may be had on the Premises; of the principal Seedsmen; and of the Auctioneers, Leytonstone.

EXTENSIVE SALE OF NURSERY STOCK.

MESSRS. PROTHEROE AND MORRIS beg to announce they have received instructions to sell by Auction, on the Premises, Windmill-lane, Camberwell, on Monday, 28th of October, 1844, and following days, at Eleven o'clock, a most valuable and varied collection of Hardy Trees, Shrubs, American Plants, Evergreens, blooming Camellias, Ericas, &c. Amongst the stock will be found some fine bearing Mulberries, and several hundred of fine straight young plants of ditto. There are also fine Magnolias of sorts, strong Vines in pots, Climbing and other Roses, a first-rate collection of choice American Plants, and other valuable Shrubs, affording a most eligible opportunity for Nurserymen providing themselves with healthy stock. A portion of the American Plants, Shrubs, &c., will be lotted in various quantities to suit all customers. Catalogues may be had of the principal Seedsmen, and of the Auctioneers, American Nursery, Leytonstone.

NURSERY STOCK.

TO BE SOLD BY AUCTION, by MR. J. KING, on the Premises, Ashe-lane, Bristol, on MONDAY, Oct. 14, 1844, and following days, precisely at 12 each day, the property Mr. Dawson; consisting of a collection of EVERGREEN and DECIDUOUS SHRUBS, a large stock of Fruit and Forest Trees, Camellias, and other Greenhouse Plants, &c. &c. To be viewed till the Sale; Catalogues of the Premises; of the Auctioneer, Bristol; and Messrs. Lee and Kennedy, Nurserymen, Hammersmith.

TO MARKET GARDENERS.

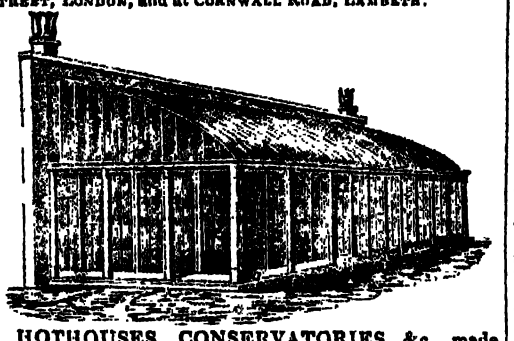
TO GET A SMALL COTTAGE, with Land, Rent Free, for a good Market-Gatter or Gardener, and Cow to be kept, with Gardening Utensils. Rent very low.—Direct, post paid, to G. BELL, Hornsey Road.

STEPHENSON AND CO., 61, Great Russell-street, Bloomsbury, and 17, New Park-street, Southwark, Inventors and Manufacturers of the Improved CONICAL and UPRIGHT CYLINDRICAL BOILERS, respectfully solicit the attention of scientific Horticulturists to their much approved method of applying the Tank system to Pineries, Propagating Houses, &c. by which atmospheric heat as well as bottom heat is secured to any required degree without the aid of pipes or flues. S. & C. have also to state that at the request of numerous friends they are now making their Boilers of Iron as well as Copper, by which the cost is reduced. These Boilers, which are now so well known, scarcely require description, but to those who have not seen them in operation, prospectuses will be forwarded as well as reference of the highest authority; or they may be seen at most of the Nobility's seats and principal Nurseries throughout the kingdom.

S. [illegible] their Manufactory in New [illegible] the construction of Horticultural buildings [illegible] them, may be obtained upon the most advantageous terms.

Conservatories, &c. of Iron or Wood, erected upon the most ornamental designs. Balconies, Palisading, Field, and Garden Fences. Wire Work, &c. &c.

HOT-WATER APPARATUS FOR HEATING HORTICULTURAL BUILDINGS, DWELLING-HOUSES, CHURCHES, and MANUFACTORIES, upon improved principles, and at very moderate charges, erected by DANIEL and EDWARD BAILEY, 272, HOLBORN.



D. and E. BAILEY having devoted much time to the consideration of this subject, and had much experience in the erection of apparatus for the above-mentioned purposes, have, by improvements suggested in their practice, rendered their mode of heating not only very efficient, but very simple, and have combined durability in the apparatus with economy in the charge. They have erected apparatus in England, Scotland, and Ireland, for many noblemen and gentlemen, and have had the honour to be employed by the Horticultural Society of London, in executing the works of their splendid Conservatory, lately erected at Chiswick.

D. and E. BAILEY also construct in metal all descriptions of Horticultural Buildings and Sashes, and invite noblemen, gentlemen, and the public to an inspection of their various drawings and models, at 272, Holborn, where they have the opportunity of exhibiting, amongst other metal works, an extremely complete and convenient kitchen apparatus, or range, adapted for the continued supply of hot water, and an arrangement of the oven more complete than has hitherto been brought before the public.

D. and E. BAILEY were the first to introduce metallic curvilinear houses to horticulturists, and can refer to the Conservatory attached to the Pantheon as one of their works, besides many others in this country and on the Continent.

D. and E. BAILEY have prepared a quantity of the Galvanic Plant Protectors, which are now ready for immediate delivery; they beg to introduce to public notice a new Trough Pipe, for Orchidaceous or other Houses where vapour is constantly, or at intervals required, and which may be seen at their Manufactory.

COTTAM AND HALLEN, ENGINEERS, IRON-FOUNDERS, &c., &c., No. 2, WINSLEY-STREET, OXFORD-STREET, LONDON, and at CORNWALL ROAD, LAMBETH.

HOTHOUSES, CONSERVATORIES, &c., made upon the most improved principle, either of iron or of iron and wood combined, which can be fixed complete in any part of the Kingdom, at very low prices.

HOT-WATER APPARATUS for heating Hothouses, Conservatories, and Greenhouses; Churches, Public or Private Buildings, &c., with COTTAM'S PATENT or ROGERS'S BOILERS. After 15 years' experience, and having fixed upwards of 2000 Apparatus for the above-mentioned purposes, and by various improvements which they have made during that time, C. and H. can with confidence undertake the erection of similar Apparatus upon the most extensive scale.

Materials may be had for those who wish to fix their own Apparatus.

THE TANK SYSTEM on an improved principle, that will heat the house at the same time, without pipes.

IRON HURDLES, best Wire for Strained Fencing, Ornamental Iron and Wire-work, Garden Chairs, &c., &c., and every description of Implement for AGRICULTURAL and HORTICULTURAL PURPOSES.

Show Rooms at their Manufactory, 2, Winsley-street, Oxford street, where a large assortment of the above can be seen.

WHEAT-SOWING.

GUANO; Genuine Peruvian, Bolivian, and Ichaboe, on Sale; also Potter's Guano, Gypsum, Sulphuric Acid, Sulphates of Iron and Copper, and all other manures. Synopsis of prices, and mode of use, on application, &c.—Apply to MARK FOTHERGILL, 40, Upper Thames-street.

GUANO (GENUINE PERUVIAN & BOLIVIAN) ON SALE, BY THE ONLY LEGAL IMPORTERS, ANTONY GIBBS AND SONS, LONDON; WM. J. MYERS AND CO., LIVERPOOL; And by their Agents, COTESWORTH, POWELL, AND PRYOR, LONDON; GIBBS, BRIGHT, & CO., LIVERPOOL and BRISTOL. 47, Lime-street, Oct. 11, 1844.

GUANO for SALE, in Bags of 1 cwt. each, just landed, with a succession of cargoes to arrive.—Successive years' experience has unquestionably proved that Genuine Guano is the simplest, cheapest, and best Manure within the reach of the Agriculturist. The only reasonable anxiety which now remains is to procure the Guano unadulterated, and to obtain such practical directions for using the Manure as shall fully develop its productive powers. To assure to buyers these indispensable requisites, with each purchase will be given a warranted chemical analysis of quality, and also a copy of the recently-published Pamphlet, "Practical Instructions for using Guano as a Manure, Illustrated by Practical Results."

Large parcels will be delivered direct from the ship or waterside premises; smaller quantities may be had at the Warehouses, No. 2 and 4, Billiter-street, or delivered within any reasonable distance of a cartful additional cost. Apply to JAMES CLARK, 2a, Billiter-street.

[illegible] MANURE, Nitrate for Wheat, [illegible] Rape-cake, 7l. per ton. To be [illegible] Factory, Deptford, near London.

[illegible] of Lime, in a concentrated form, may also be obtained at 40s. WARREN'S 33, Cornhill, in 7 lb. packets, price 1s.

POTTER'S GUANO MANURE is the only Guano that can positively be depended upon, and has stood the test of three seasons. The imported article, it is well known, is seldom twice alike, even when genuine, and is subject to an extensive system of adulteration. Orders addressed, post paid, to the Works, 32, Upper Fore-street, Lambeth, will have instant attention. Testimonials will be sent per post, if required.

POTTER'S LIQUID GUANO may be had as usual of most Chemists and Seedsmen.

*** Beware of being imposed upon by ineffectacious imitations.

INVESTMENT TO AGRICULTURISTS, &c.

ANALYSES of SOILS, MANURES, and all AGRICULTURAL PRODUCTS, are conducted by Professor, Mr. and Mr. Mitchell), Analytical Chemists, with the view of ascertaining whether the Soil in which it is proposed to grow any particular crop, contains all that is necessary to produce a luxuriant vegetation; and to estimate the relative value and purity of Manures, and the comparative worth of Farm Produce in general. Gentlemen instructed in Agricultural Chemistry. The course will comprehend the Elements of Analysis.—No. 5A, [illegible], Kentish Town.

LIQUID MANURE.

ENGLAND INDEPENDENT OF THE WORLD FOR CORN.

THE Attention of the Agricultural Interest, at this momentous crisis, is requested to the great importance of LIQUID MANURE, and the ease with which it may be appropriated, by the use of FOWLER'S PUMPS, chiefly adapted for the purpose, either portable or fixed; Garden, Chain, and Barrel Pumps; also those for Distillers, Brewers, [illegible], and Tanners, for hot and cold liquor. Pumps for Mines, for Excavations and Wells. Buildings heated by Hot Water, for Horticulture, and every variety of manufacturing purposes.

The Trade supplied on advantageous terms, by HENRY ADDY FOWLER, Engineer, &c., 63, Dorset-street, Fleet-street, London.

BY HER MAJESTY'S ROYAL LETTERS PATENT.

PATENT ASPHALTE ROOFING.

THE above Material has been used and approved by the Nobility, Gentry, and Agriculturists generally, as a Roofing and Covering to sides of Farm Buildings; its advantages are—Lightness, Durability, and Economy. Being a non-conductor, it has been proved an efficient Protective Material to Plants, and is now in use at the Royal Horticultural Society's Gardens, Chiswick. It can be had of any length, 32 inches wide, at 1d. per foot, super. A discount to the trade. THOS. J. CRODDON, 8, Ingram-court, Fenchurch-st., London.

CHEAP AND DURABLE ROOFING.

BY HER MAJESTY'S  ROYAL LETTERS PATENT.

TO GARDENERS, NURSERYMEN, AND OTHERS.

F. M'NEILL & CO., of Lamb's Buildings, Bunhill-row, London, Manufacturers, and only Patentees of IMPROVED PATENT ASPHALTED FELT for Roofing Houses, Sheds, Verandahs, &c., and for Protecting Plants, and Covering Garden Frames, beg to call the attention of Gardeners and others to their superior article, which has been exhibited at the Great Agricultural Shows of England, Scotland, and Ireland, and OBTAINED the PRIZE for being the best and cheapest article for roofing, &c. It has been tested in the gardens of several noblemen and gentlemen in the neighbourhood of London, and in different parts of the country, to whom reference can be made. The Felt is impervious to rain, snow, and frost, and a non-conductor of heat and sound. Its advantages are Lightness, Warmth, Durability, and Economy.—Price ONLY ONE PENNY PER SQUARE FOOT.

Samples, with directions for laying on, and testimonials as to its merits, sent free to any part of the town or country.—Patent Felt Works, Lamb's Buildings, Bunhill-row, London.

TO LANDOWNERS, AGRICULTURISTS, BUILDERS, &c.

McKIBBIN'S Improved ROOFING FELT is peculiarly applicable as a substitute for Slate, Zinc, Tiles, and other articles used for Roofing, from its ECONOMY, LIGHTNESS, and DURABILITY.

The disadvantages attending other materials used in roofing, preventing, to a great extent, many useful houses and sheds being erected or rendered waterproof, it is submitted that the improved Roofing Felt will in a great measure—and in some instances altogether—obviate them, and prove most serviceable from its lightness, durability, and impermeability to water and damp, in covering Houses, Cattle-sheds, Workshops, Ropewalks, &c., and for the sides, as well as roofs, of light structures for plants, being likewise a non-conductor of heat; besides its economy in repairs, the timber where it is used may be so light as to save its whole expense; it requires no other coping, and may be applied by any person of common ingenuity; being flexible and portable also, it is free from breakage, the expense of carriage is inconsiderable in comparison with slates, tiles, &c., and it is not liable to contraction like zinc.

Sold in sheets 32 inches by 30, at 4d. each (being less than 9s. 6d. per square of 100 feet), with printed directions for applying them, same as adopted at the Government Dock-yards and various other public buildings.

Orders will meet with prompt attention if addressed to H. C. BOWDEN, 16, East India Chambers, Leadenhall-street, London, or to the following agents:—Liverpool, Messrs. Grueber & Co., 11, Manesty-lane; Plymouth, Thomas Stevens, Esq.; Birmingham, William R. Lloyd, Esq.; Sunderland and Newcastle-on-Tyne, Messrs. John Ritson and Sons; Hull, William Ward, Esq.; Bristol, Messrs. Moor and Hewitts; Ramsgate and Deal, Messrs. Edward Hodges & Co.; Whitehaven, William Todd, Esq.; Glasgow, Malcolm Carmichael, Esq., 61, Enoch-square; Cork, Messrs. Richard Wallis & Co.; Belfast, Messrs. Grueber & Co., Dunbar's Dock; who have also on sale McKibbin's improved SHEATHING, BOILER, RAILWAY, and SHIP FELT.

*** The "IMPROVED ROOFING FELT" will be found much more durable than the Common Felt made in lengths, and not subject, like it or continuous sheets of other material, to be stripped by storm; it can also be more easily repaired; and from the simple mode of application recommended, the wet cannot percolate through nail-holes, being only fastened down at the overlaps.

PORTER'S GALVANIZED CORRUGATED AND PLAIN IRON ROOFING, and IRON HURDLE and FENCE WORKS, Grove, Southwark. The Patent Galvanized Iron Co.'s (Sorel's) Process has been highly approved for the Roofing of the New Houses of Parliament, by Woolwich Dockyard, by the Trinity Board, &c. &c., and is particularly suited for the Colonies, and is shipped to all parts, to the East and West Indies, Cayenne, &c.; also [illegible] to several Englishmen and to the Australian Government. Movable Feeding Sheds and Pens, Fencing, Gates, Buildings of all kinds, a new description of Galvanized Iron Gutter combined with tile for the roof, which is much cheaper than any other kind. The Trade supplied with Corrugated Plates, Galvanized or not, and with Iron Fences of all kinds.

DRAINING OF LAND.

THE A LEVEL, designed for the Use of Workmen, in preserving a uniform fall in Drains and Water courses In consequence of the approval expressed and the demand made for these Levels at the recent Southampton Show, Mr. BARNEY Derwent has prepared with an eminent London Mathematical Instrument Maker to make them in any number required Price 30s

This Level is as accurate as a spirit-level, and so simple that the workman unable to read can use it with facility When closed it forms a 5-feet staff

Orders addressed to Mr DERWENT Land Agent 9, Gray's Inn square, London; or to Mr CHARNOCK, Wakefield, Yorkshire, will [illegible] instrument

AGRICULTURAL DRAINING — THE DERBY [illegible] attention of persons draining their land [illegible] efficient but simple Instrument, presumed to be all that can be required for the purpose and its price such as to place it within the reach of all To be had of the Maker, J DAVIS Optician, Derby

SEED WHEAT.—Donnington, near Stow, Gloucestershire.—From the number of testimonials received of the extraordinary crops produced both this year and last, ROBERT LEMAN is induced to offer to the public his Red Cluster Wheat, which both seasons has produced 60 bushels per acre in several instances, and, having been grown upon old turf, and hand picked before it was planted, it is beautiful seed, and perfectly clean Price 7s 6d per bushel

R L has likewise a small quantity of the celebrated Whitfield Red Straw White Wheat to dispose of Price 8s. per bushel

Orders, accompanied by a remittance or good reference, punctually attended to Sacks marked 1s 6d each

SEED WHEAT.

J. D. PIPER, of Colne Engaine, Essex, (Member of the Royal Agricultural Society), has been four years raising two new Stocks of Wheat, viz, Piper's "Think set," and "Colne Whitechaff Red" At the last Southampton Meeting two samples of these Wheats were exhibited outside (notice not having been given in time for their admission inside), where they produced much excitement, and 6d per ear was offered for them Last year, in the same field, side by side, the Piper's Think set grew eight bushels and a half, and the Colne White chaff Red five bushels and a half more per acre than the most prolific Wheat grown in the neighborhood Last autumn J D P measured a quarter of an acre off his field, and dibbled the Think-set in rows a foot apart, and one bushel per acre; and though the plant was partially destroyed by the slug in the winter, and a good sprinkling of self sown Potatoes were left to grow, still the yield was 14 bushels and a half, being equal to 14 sacks and 3 bushels per acre One person this year grew 15 sacks and 2 bushels, another 14 sacks, and another 13 sacks per acre One parcel weighed 64lbs per bushel This is, perhaps, the stiffest-strawed Wheat in England, and is adapted for strong or hollow bottom ground, and is not likely to get laid J D P will send to London, or to any place within ten miles of Colne carriage free, and he will be glad to receive a post office order, or reference to some house in London for the money, with the order for the Wheat. When it is all sold, J D P promises to inform the Public, by an advertisement in this Paper; but if he should get any post office orders after it is all sold, he will return them The price is regulated according to the yield Think-set, 15s per bushel; Colne Whitechaff Red, 5s per bushel Samples of the above, both threshed and in the straw, may be seen at our Office N B—J D P advertised in the two principal papers in Essex, where the above Wheat was growing, to order that Agriculturists might see it and judge for themselves of the quality and quantity

WHEAT SOWING

FREDERICK BRAIN begs to call the attention of the Agricultural world to his GUANO MANURE, prepared expressly for Wheat crops It abounds in all the ingredients that are necessary for a good grain crop He particularly solicits persons who found the Foreign Guano a failure last season to give his a trial it being much more powerful and free from adulteration, as justly complained of in the Foreign by Agriculturists, as well as by all the leading Agricultural Journals

Testimonial to Brain's Guano Manure.—"I, A, Hawley Road Kentish Town, London, Aug 18, 1844—This is to certify that we have subjected Brain's Guano to a most patient and rigorous analysis, and find it contains all the necessary constituents of a good manure, and is well calculated to give fertility to a soil which is either naturally barren, or has been exhausted by over cropping by supplying the land with those substances which are absolutely requisite to a healthy vegetation (it is not adulterated) and can always be depended on, being of uniform composition —(Signed) JOHN MITCHELL and FREDERICK KIRBY, Analytical Chemists late of the Royal Polytechnic Institution, London"

Also, BRAIN's highly concentrated LIQUID GUANO, for Grass Lands, Gardens, Shrubberies, Hothouses and Conservatories, price 9s per quart bottle, with full directions for use, (enough for 250 gallons of Liquid Manure), to be had of most respectable Florists, Seedsmen, and Chemists in town and country

Works, Thomas st, Duke st Stamford st Blackfriars road

J. R. AND A. RANSOME, Ipswich have published a Descriptive Catalogue with Cuts of their AGRICULTURAL IMPLEMENTS and MACHINE which may be had by post, the order being accompanied by six penny stamps

Price Sixpence, free by post

London LONGMAN, BROWN, GREEN, and LONGMANS.

RAY SOCIETY, instituted 2d February, 1844.—This Society has been formed upon the principle of the Parker, Camden, Sydenham, and other Societies, for the purpose of securing to those attached to the study of Natural History, such Works on the various branches of Zoology and Botany as could not be obtained by other means, and will consist of original works, of new editions of works of established merit, of rare tracts and MSS; and of translations and reprints of foreign works Every subscriber of One Guinea annually will be considered a member of the Society, and will be entitled to a copy of every work published by the Society The Council have great pleasure in stating that the number of Members already exceeds 300, and beg to call the attention of their friends to the necessity of sending in their names as early as possible, in order that they may be enabled to determine the number of copies of their works which they ought to print The Council hope to publish two volumes before Christmas, the first of which will consist of translations from the German and Italian, of Reports on the progress of Zoology and Botany during the last few years.

Communications on the business of the Society are requested to be addressed to the Secretaries, Dr George JOHNSTON, Berwick upon Tweed, and Dr Lankester, Golden square, London. Subscriptions to be sent, by post-office order or check, to the Treasurer, J S. Bowerbank, Esq, 45, Park street, Islington.

GEORGE JOHNSTON, M D } Secretaries.
EDWIN LANKESTER, M D }

DOMESTIC COMFORTS.—READ'S STOMACH and ENEMA PUMPS have long had the reputation of being the best instruments of the kind ever offered to the public (vide the Life of Sir A Cooper) This distinguished patronage has induced some unprincipled adventurers to palm upon the public imitations of Read's Patent Instruments, which has been made known to the Patentee by the number of spurious instruments which are daily sent to him from all parts of the Kingdom, and frequently from India, for repair, some not worth the expense of carriage. As a protection in future, J READ has directions from the Hon. East India Company to place their mark on all his instruments sent to their Presidencies. The above are manufactured only by the Patentee, 75, Regent circus, Piccadilly Likewise improved ENEMA FOUNTAINS, with tubes that require no fixing or screwing, or the incumbrance of a stop cock, &c, but which are as durable as the instrument itself, and are not affected by the hottest climate. May be seen and proved at 75, Regent-circus, Piccadilly

N B—Observe the Words "READ's PATENT," without which none are genuine.

TANNER'S VITREOUS CLOTH, a SUBSTITUTE for GLASS for HORTICULTURAL PURPOSES—The above recommends itself to the notice of Florists and Horticulturists, as producing effects superior to Glass, at a less expense The support the Proprietor has received from very many highly respectable Florists encourages him to consider that his labours have not been misapplied in bringing before the public an article so generally required Price of cloth, 7 8ths of a yard wide, thin, 2s 6d per yard; stout, 3s 1 yard wide 3s 6d Price of Fluid (for renewing the cloth after lengthened service), 4s 6d and 2s 6d per bottle Manufactured only by N W TANNER, Chemist, Exeter; and Sold by Messrs Butler and Mackley, Covent-garden London, Mr. Cunningham Paradise-street, Liverpool, Messrs Lucombe and Pince, Exeter Nursery

H. WALKER'S NEEDLES (by Authority the "Queen's Own") have large eyes, easily threaded, (even by blind persons), and improved points, temper, and finish Each paper is labelled with a likeness of Her Majesty or His Royal Highness Prince Albert, in relief, on coloured grounds. Every quality of Needles, Fish hooks, Hooks and eyes Steel Pens, &c, for shipping These Needles or Pens for the home trade are sent free, by post, by any respectable dealer, on receipt of thirteen penny stamps for every shilling value

H WALKER, manufacturer to the Queen, No 1 (late 20), Maiden lane, Wood-street, London.

BURRIDGE AND HEALY'S COOKING APPARATUS, combining Sylvester's Patents—This Cooking Apparatus is believed to possess greater general advantages than any yet submitted to the Public, both as regards strength of material and workmanship, in fact, the laws of heat are so applied as to produce the greatest effect with the least consumption of fuel, without destruction to the Apparatus; and B & H can safely recommend it, from experience, as unquestionably superior to anything of the kind hitherto made A Prospectus can be forwarded, upon application, detailing particulars and prices, to 130, Fleet street

SILVER TEA-SERVICES.—A. B. SAVORY and SONS, Manufacturing Silversmiths, 14, Cornhill, London, opposite the Bank of England, submit the price of the following Silver Tea and Coffee Services The Cottage Pattern is plain, standing on shell feet, the tea and coffee-pot with a flower ornament on the lids. The King's Pattern is richly embossed with flowers and scrolls The shape of either is new and elegant.

All the plants are strong, healthy, and well established, and will be forwarded immediately on receipt of order.

Union Road Nurseries, Plymouth, Oct. 17, 1844.

REMOVED TO HIGHER HOMERTON.

E. P. FRANCIS begs respectfully to inform the Nobility, Gentry, and Public, that he has removed to the above place, where he intends carrying on the Nursery and Seed business in all its branches, and will be forwarded [illegible] upwards of a thousand Varieties.

E. P. F. begs to inform the Nobility, Gentry, and Public that he has made an addition to his Stock of Greenhouse Plants, and has now in Flower a large stock of Fuchsias, Cinerarias, Calceolarias, Petunias, Verbenas, Salvias, Heliotropes, Pelargoniums, &c., of which he has a large stock of Fuchsias and Cinerarias, and all other Greenhouse and healthy sorts, including Standards, all of which are [illegible]

LOUDON'S [illegible]

THE TRUE FASTOLFF RASPBERRY.

YOUELL AND CO. beg to announce they will again be able to supply fine canes of the above truly excellent variety, unequalled for the size of its Fruit and richness of flavour, prices as follow:—

Packages containing 100 Canes	£2	0	0
Ditto " 50 "	1	1	0
Ditto " 25 "	0	12	0

Further particulars will appear in future Advertisements.

YOUELL and Co. feel it due to themselves to state that a spurious kind was offered for sale by other parties last season, under the title of "Fastolff Raspberry," the same having no pretensions to the genuine variety.

☞ For Particulars of their EXTENSIVE and SELECT COLLECTION OF CARNATIONS, PICOTEES, PINKS, Finest Imported DUTCH HYACINTHS, &c. see their Advertisement of last week.

Great Yarmouth Nursery, Oct. 17, 1844.

TULIPS, CAMELLIAS, &c.—A gentleman wishes to dispose of his stock of Tulips, amongst which are Pompe Funebre, Polyphemus, Albion, Louis XVI., Claudiana, Cerise blanche, and other choice sorts. Any one wishing to add to their stock, or commencing the culture of these flowers, will find this a favourable opportunity. A mahogany Tulip Cabinet, with Drawers for 160 roots, some separate Drawers, a frame with awnings, &c., complete, are also to be disposed of. Also, a few Camellias, well furnished with blooming buds, Geraniums, and other Greenhouse Plants. Apply between the hours of 2 and 4, at Brantly Cottage, Hill-street, Peckham.

SPLENDID NEW GERANIUM—BECK'S "ZAMUMMIM."

LUCOMBE, PINCE, and Co., possess the Entire Stock of this very celebrated Geranium, raised by Mr. Beck, of Isleworth; it has been much admired wherever it has been exhibited, and was awarded the First Prize for Seedlings at the Exhibition of the Royal Botanic Society, Regent's Park, on the 24th of May, 1843. It also obtained a Certificate of Merit from the London Horticultural Society, on the 18th of May, 1843. It will give satisfaction to all who purchase it, and is indispensable in all first rate Collections.

L., P., and Co., are now prepared to execute orders for it with strong Plants at 21s each. A full description of this superb flower will be met with in their Catalogue of New Geraniums, just published, which may be had on application to them, Exeter Nursery.

RODGER'S "GENERAL TOM THUMB" PINK.

SAMUEL HODGES begs to inform the admirers of the Pink that he is sending out Strong Plants, at 5s. per pair, of the above-named unique variety, the guard leaf being broad and flat, with a perfect smooth edge, and narrow purple lacing, as regular as if drawn with a pencil, and beautifully crowned. The undermentioned can supply plants:—

Messrs. Hooker & MacMullen, 3, Leadenhall Street, London
Mr. Willmer, Florist, Sunbury. Mr. Kennan, Florist, Salisbury. Mr Lodge, Florist, Manchester.

S. H. has also good plants of Pinks, of Hodges' Gem, Melone, Mars, Pluto, Cyrus, Orion, Invincible, Devonia, Clio, Enchantress, Jupiter, Olimax, with a great variety by other growers, at 1s per pair.—Imperial Nursery, Cheltenham, October 17.

CHAPMAN'S KIDNEY POTATO.—Messrs. C. and T. CHAPMAN, of Brentford End, are ready to execute orders for their POTATO at 10s per bushel, any person desirous of seeing the quality and the yield can do so by applying to Mr. T. Chapman, Elm Hill, Brentford End, when instructions for their preservation and culture will be given.—Oct 18.

Mr. HOYLE'S NEW SEEDLING GERANIUMS.

MR. MILLER will commence sending out the above CHOICE PLANTS on the 23d inst. Printed lists, with full descriptions, may be had on application.

Providence Nursery, Ramsgate, Oct. 18.

TRAINED PEACHES AND NECTARINES.

WM. E. RENDLE respectfully informs the Nursery Trade that he has this season a large stock of TRAINED PEACHES AND NECTARINES, strong, healthy, and in excellent condition.—Union-road Nursery, Plymouth, Oct. 17, 1844.

A SPLENDID NEW LATE PEACH.

MORTON'S "WALBERTON ADMIRABLE."—This splendid variety was raised at Walberton House, in Sussex, the seat of R. Prime, Esq. It is a Seedling from the Noblesse, which it much resembles, both in size and colour. It ripens on the 2nd fortnight of its parent, but its great merit arises from its ripening full five weeks later. Specimens of its fruit were sent to the Horticultural Society in 1841, from whom were received the highest testimonials of approbation. The tree is a fine, free, and handsome grower, the fruit is full-sized, swelling, and excellent-flavoured, ripening; it is a truly desirable variety, and one which no fruit garden ought to be without. Good one years trained plants are in readiness at Mr. Morton's Nursery, Westergate, near Arundel, Sussex; also at Messrs. Hay, Portsmouth, and Shrubbery, Southampton; and also at Messrs. Rivers' and Pulham's, Sawbridgeworth, Herts

NEW CARNATIONS.

LUCOMBE, PINCE & CO. respectfully inform the Public, that their Catalogue of New Carnations is just published, and may be had on application to them; it will be found to contain many very splendid varieties, such as are quite indispensable in all good collections.—Exeter Nursery.

BAGSHOT NURSERY (late HAMMOND'S).

GEORGE BAKER, late of Knap-hill, has to inform his Friends and the Public, that, under an agreement entered into in July last, he has become the tenant of the Bagshot Nursery Grounds, formerly for many years occupied by Mr. HERBERT HAMMOND. Mr. BAKER is adding considerably to the stock, rendering it superior in quality and of greater variety than has hitherto been kept at this Nursery. All letters addressed to Mr. BAKER, Bagshot Nursery, Surrey, will be punctually attended to.

CAMELLIA JAPONICA.

ROBERT LAWSON, Esq., of Tiverton, intends disposing of his stock of Camellias, which he has collected at much expense, and successfully cultivated for many years. They are in the highest state of health, and most abundantly set with blooming buds. Mr. L. disposes of them solely in consequence of their having become too large for his conservatory. They are as follow:—

			£	s.	d.
Reticulata,	from 7 to 8 feet in height, a very fine specimen, quite healthy and green		10	10	0
Imbricata,	from 7 to 8 feet in height,	do.	8	8	0
,, ,,	5 to 6 ,,		1	10	0
Eximia ,,	7 to 8 ,,	a magnificent plant	7	7	0
Chandleri ,,	6 to 7 ,,	a fine plant	5	5	0
,, ,,	3 to 4 ,,		1	10	0
Lady Hume's Blush	6 to 7 ,,	fine	4	4	0

Lawsonii ,,	3 ,,	new	1	10	0
Colvilii ,,	2 ,,		0	10	6
Donkvarii ,,	2 ,,		0	10	6
Insignis ,,	6 to 7 ,,	very fine	2	10	0
Eclipsa (Fraser's)	6 to 7 ,,		3	3	0

The Prices affixed are for the separate plants, of which not less than 3 can be taken together. If the whole are taken in one lot a considerable reduction will be made. Mr. Lawson will be happy to show them, or give any further particulars that may be required.—Tiverton, Oct. 16th, 1844.

NEW CARNATIONS, PICOTEES, AND PINKS.

MESSRS. N. and B. NORMAN'S CATALOGUE of SHOW VARIETIES can be had on prepaid application.—Bull Fields, Woolwich.

NEW PLANTS.

MESSRS. VEITCH AND SON have now ready for sending out the two undermentioned beautiful New Plants, viz.:—

HIBBERTIA VOLUBILIS. Strong plants at 63s. It is figured by Dr. LINDLEY, in the "Botanical Register" for August last, who there says—"The Hibbertia volubilis is one of the finest things obtained from South Brazil. It has been imported, by Messrs. Veitch and Son, of Exeter, who received for it the Large Silver Medal at the Horticultural Society's Garden Exhibition in May last. It will doubtless prove a very easily cultivated Greenhouse Plant; and is certainly unsurpassed in beauty by blue-flowering shrubs."

CLITORIA FULGENS. Strong plants at 42s. This plant was exhibited at Chiswick, in May, under the name of Centrosema specios, and received the Knightian Medal. See Report in *Gardeners' Chronicle* for May 25. It is figured in "Paxton's Magazine" for July last.

Messrs. V. and Son have also to offer the following fine plants, viz.:—

Achimenes picta	Gardenia Sherbourneæ
Allemanda grandiflora	,, tetrasperma
Barbacenia squamata Veitchia	Gesneria polyantha
Clerodendron lævifolium	Gloxinia Cartonii
,, splendens	Hundsia longifolia
Cyrtoceras reflexa	Inga pulcherrima
Echites atropurpurea	Luxemburgia ciliosa
,, hirsuta	Passiflora actinea
,, splendens	Pentas carnea
Gardenia Rothmannia	Thunbergia chrysops, &c. &c.

N.B.—Messrs. V. and Son's General Catalogue can be had on application.—Exeter, Oct. 16, 1844.

DOUBLE ROMAN and PAPER-WHITE NARCISSUS, 4s. per dozen. The above Bulbs, the former of which is so justly esteemed for its early blooming and excessive fragrance, and the latter for its purity and elegance, have been just received at A. CONSTE'S, late Mr. BARRON'S, Italian and Foreign Warehouse, 18, Pall Mall. Also Dutch Hyacinths, Crocus, Tulips, Anemones, &c. &c. Price Catalogues of which may be had per Post.

THE GREATEST NOVELTY EVER OFFERED TO THE PUBLIC.

RHODODENDRON JACKSONII.—This splendid new hardy Rhododendron is confidently recommended as the most beautiful variety extant; it surpasses in the colours of its flowers the richest Nassarium, and is quite a new feature in this noble family. It forms well, is a free bloomer, and of dwarf habit. A truss of flowers was transmitted to Dr. Lindley, who pronounced it "a very distinct and handsome variety," with "great richness in its flowers appearance, &c. See *Chronicle* of the 6th April last, page 211, "*Rhododendron*.—*C. L. N.*" To be sent out in March at 21s. each.

WM. JACKSON and Co. beg leave to call the attention of the Nobility, Gentry, and the Trade, to their following rare and valuable Rhododendrons, all warranted [illegible] at the very low prices attached. The Plants are [illegible] and stout, twice transplanted, and ready to send out.

Rhododendron campanulatum, averaging [illegible] per doz.

CARNATIONS AND PICOTEES.

JOHN DICKSON, Springfield, Upham, Surrey, has prepared for the [illegible] of his splendid stands a Catalogue, enabling them to judge of their qualities, with the prices annexed, which may be had at the Nursery, and of Messrs. WARNER & WARNER, Cornhill, London, after the 7th September.

DANECROFT NURSERY, STOWMARKET, SUFFOLK.—PETUNIAS, BEDDING VERBENAS, DAHLIAS, &c.

S. GIRLING has much pleasure in announcing to his Friends and the Public generally, that he has been successful in adding to his already extensive collection of Verbenas some splendid Seedlings of the present year, which for colour, form, and size far surpass any Verbenas yet produced; in confirmation of which S. G. begs to refer the public to the following awards they have received, and reports that have been made of them, viz., an Extra Prize at the Ipswich Show in June, Stowmarket in July, Ipswich in September, Bury St. Edmunds, do., Stowmarket, do., and Chelmsford, open Show; and favourably noticed by Dr. LINDLEY in the *Gardeners' Chronicle*, August 31, and in the *Gardeners' Gazette* by Mr. GLENNY, August 31. Mr. AYRES also speaks of them in flattering terms in the *Gardeners' Chronicle*, Oct. 5, page 671; and in addition to the above testimonials they have been seen growing by many eminent Horticulturists and Amateurs, all of whom have considered them as very superior.

S. G. therefore offers them with full confidence of their giving general satisfaction.

	s.	d.
Alba Lutescens, sulphur-yellow, large, and sweet-scented	3	6
Alba Magna, the largest and best white out	3	6
*Blanda, rosy-blush of excellent form	3	6
*Gladiator, orange-scarlet, with deep yellow eye, fine	3	6
Lovely Rambler, grey-lilac, very large	3	6
Messenger, bright-purple, of fine shape	3	6
*Mulberry, bright-mulberry, quite new in colour and fine	3	6
Rose de Amour, bright-pink, with beautiful yellow eye, quite distinct, and the most attractive Verbena ever raised	5	0
*Rubescens, bright-ruby, large and well-formed	3	6
The Giant, silvery-lilac, the largest trussing Verbena known, some of the trusses measuring from 10 to 12 inches in circumference—the heads of this Verbena resemble in appearance a blue Hydrangea	5	0

N.B.—Those marked with an * will not be sent out till early in May; the others can be had after the 25th of October, and can be forwarded in tin boxes by post. The usual allowance to the Trade.

PETUNIAS.—S. GIRLING has likewise been successful in raising some Petunias of superior excellence. Twelve varieties, selected from about fifteen hundred seedlings, will be sent out as early as possible in the spring, far surpassing anything in that fine and beautiful class of plants. Nurserymen wishing to be appointed agents are requested to forward their names, which will be published in the *Chronicle* and *Gazette* before sending out. The usual allowance to the Trade. Advertisements with names and prices will shortly appear.

DAHLIAS.—S. GIRLING having purchased the entire stock of that beautiful Dahlia, Bourne's Marchioness of Ormond, the best light-tipped Dahlia of the season, similar but far superior to Bridesmaid in every respect, plants will be sent out early in May next, at 10s. 6d. each. A few roots would be parted with, on the warranty of the party purchasing, for exportation only, and the party to whom sent giving a pledge not to send plants to England for sale. Nurserymen and dealers wishing to place this Dahlia in catalogue next season, will have their names published in good time before sending out, and the usual Trade allowance, where 12 Plants are ordered, and extra Plants to compensate for long carriage.

DAHLIA NONPAREIL.—S. G. has a few large and small ground roots of that beautiful and popular Dahlia to dispose of; the former at 20s., the latter at 10s. each. From the limited number sent out in England last season of this Dahlia, it will be more in demand than any other Dahlia sent out last May. Parties wishing for roots had better send their orders early, as the stock, which is limited, will be sent out in rotation, as the orders are received; almost every other kind of Dahlia in cultivation, embracing nearly all the favourite varieties of this and former years, can be had in dry roots at moderate prices, warranted correct to name.

N.B. A respectable reference or ready money will be required from unknown correspondents.

Foreign Orders faithfully executed.

Dancroft Nursery, Stowmarket, Suffolk, October 17, 1844.

"GENERAL TOM THUMB" SCARLET PELARGONIUM.

PHILIP CONWAY, NURSERYMAN & FLORIST, &c., Old Brompton, through the kindness of Mr. AYRES, is enabled to let out a few plants of the above, which is thus described in the *Gardeners' Chronicle*, page 550:—

"Unquestionably the finest dwarf Pelargonium out is that which has this season been exhibited under the name of 'General Tom Thumb.' It grows almost prostrate, is exceedingly rich and dense in foliage, and produces with the greatest profusion large trusses of the most dazzling scarlet flowers imaginable. I have a plant at this moment nine inches high and six [illegible] in circumference, studded with 27 trusses of expanded [illegible], and some of the trusses six inches in diameter; and on five plants there are upwards of 120 trusses of flowers."

For both pot cultivation and bedding out this plant is unequalled. Plants 2s. 6d. each, or 30s. per dozen, with the usual discount to the trade if six are taken at one time. N.B.—At the June Exhibition of the Regent's-park Society a prize was awarded to the above.

Frost's Superb, a splendid pot plant	2s. 6d.
Mrs. Mayler, a very superior variety	2 6
Cooperii dwarf, for bedding	1 6
Hunteman, do.	1 6
Shrubland	1 to 2½.
Compactum	1 6
King	1 6
Queen	1 6
Conway's Giant Cactus, strong plants	2 6 to 10s. 6d.
Veronica speciosa	3 6
Pelargonium Lunati, for forcing	1 0 to 3 6

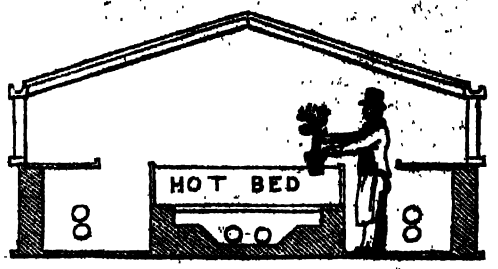
Cash, with an order, is respectfully requested from unknown correspondents.

NEW ALONA CÆLESTIS.

J. J. BEST begs to return his best thanks to those numerous friends who have ordered the above plant, and begs to say he commenced sending out on the 16th inst. Plants of the above beautiful production, at 1 guinea per plant, may be obtained as under:—Messrs. Hollinson, Tooting; Mr. Jackson, Kingston; Mr. Ivery, Peckham; Nurserymen. Mr. Carter, Seedsman, 238, High Holborn. Usual discount allowed to the trade.—J. J. BEST, Abbey Nursery, Reading, Berks.

J. THOMSON begs to inform the Cultivators of the PANSY he is now sending out strong Plants of his New Seedlings, including Pizarro and all the principal existing varieties in cultivation, at moderate prices.—Ivy, Oct. 17, 1844.

HOTHOUSES, CONSERVATORIES, [illegible], &c., made [illegible] and fixed Complete in all parts of the Kingdom. Glass, [illegible] Sash-light Ventilator and Metal Bars and Lights of all [illegible] Roofing for Immediate use, [illegible] to all parts of the [illegible]; Illustrated Lists may be [illegible]. Two Sets Bars and [illegible] Ironwork, from 14 to Garden Frames and Lights, [illegible] Hot-bed Sash, or Mr. Warth's [illegible] Ventilating Plates, Old Kent-road. ⁂ Estimates given.



HYACINTHS AND GREENHOUSE PLANTS.

HUMPHREYS'S SOLUBLE COMPOUND.—A few grains are effective. Half a bottle dissolved in a quart of water furnishes a superior LIQUID GUANO at half the usual cost. Sold in bottles, price 1s. 6d. each, by FRAMADAN and Son, Munsion-house-street; HUMPHREYS and McMURRAY, Leadenhall-street; W. CLARKE, Bishopsgate-within; SMITH, Islington Nursery; GAINSLEY and Co., Covent-Garden; BATT and BUTLEY, 312, Strand; WILLIAM and JOHN NOBLE, Fleet-street; THOMAS GLADE and Co., Piccadilly; SMITH, Covent-Garden; CHANDLER, Tavistock-row; W. J. NUTTING, 46, Cheapside; G. LAWRENCE, 19, Piccadilly; JOHN KERNAN, Great Russell-street, Covent Garden; LOCKHART, 166, Cheapside; SHUTTLEWORTH, Pantheon; MINTER, ADAMS, and NASH, 63, Strand; THATCHER and Son, Islington; J. FRYER, Clarendon-terrace, Camberwell; THOMAS ARNELL, Camden Town; THOMAS WATKINSON, Market-place, Manchester; T. S. KING, Rochester; W. E. RENDLE, Plymouth; DICKSONS and Co., Edinburgh; POWLEY, Leeds; FISHER, HOLMES, and Co., Sheffield; P. LAWSON and Son, Edinburgh; J. THORNS, Shepton Mallet; and other leading SEEDSMEN in town and country. Wholesale Agents, DAVY, Mashewabe and Co., 90, Upper Thames-street, London.

TO AMATEURS OF PLANTS, &c.

F. SEIBOLD is just arrived with a fine Collection of COLEOPTERA from Mexico, and some choice FERNS, to be had per 100; also some rare ZOOPHYTES, from the West Indies. A young German Naturalist is now going to the West Indies, Mexico, and Yucatan, on F. Seibold's account. He will take orders for Cacti, Orchidaceous, and other Plants, as also for Dry Specimens, Seeds, &c. &c. All orders must be given by the 25th inst.—270, High Holborn, Oct. 16, 1844.

HOT WATER FOR BOTTOM-HEAT.

J. WEEKS AND DAY, ARCHITECTS, &c., Gloucester Place, King's Road, Chelsea, HORTICULTURAL BUILDERS, and Hot-water Apparatus Manufacturers, invite the attention of Horticulturists to their Improved Plan of Bottom-Heat, now becoming so universally adopted.

From the extensive Practice they have been honoured with for 20 years in designing and building CONSERVATORIES, GREENHOUSES, HOTHOUSES, PITS, &c. &c., and erecting their HOT-WATER APPARATUS to every description of Buildings to which heat is applicable, J. WEEKS AND DAY have the greatest confidence in recommending their BOILERS as the most efficient of any yet invented, their largest being capable of heating a range of Forcing Houses 200 feet in length, with a comparatively small quantity of fuel, and only requiring attention once in 12 hours. To be seen in use at most of the London Nurseries, also at their Manufactory; and a variety of Horticultural Erections, Models, Plans, &c. &c.

Sales by Auction.

SIX DAYS' SALE.—VALUABLE NURSERY STOCK.

MESSRS. PROTHEROE AND MORRIS beg to announce that the Sale of the celebrated NURSERY STOCK, at the American Nursery, Leytonstone (about one mile from the railway station, Stratford), will commence on MONDAY, 21st October, at 11 o'clock, and terminate on Saturday, Oct. 26.

EXTENSIVE SALE OF NURSERY STOCK.

MESSRS. PROTHEROE AND MORRIS beg to announce they have received instructions to sell by Auction, on the Premises, Windmill-lane, Camberwell, on Monday, 28th of October, 1844, and following days, at Eleven o'clock, a most valuable and varied collection of Hardy Trees, Shrubs, American Plants, Evergreens, blooming Camellias, Ericas, &c. Amongst the stock will be found some fine bearing Mulberries, and several hundred of fine straight young plants of ditto. There are also fine Magnolias of sorts, strong Vines in pots, Climbing and other Roses, a first-rate collection of choice American Plants, and other valuable Shrubs, affording a most eligible opportunity for Nurserymen providing themselves with healthy stock. A portion of the American Plants, Shrubs, &c., will be lotted in varied collection to suit all customers. Catalogues may be had of the principal Seedsmen, and of the Auctioneers, American Nursery, Leytonstone.

ST. ALBAN'S, HERTS.

UNRESERVED SALE OF NURSERY STOCK.

MESSRS. PROTHEROE AND MORRIS are instructed by the Executors of the Mortgagee (in consequence of the Estate having been disposed of), to submit to public competition, on the premises, the Key Field Nursery, St. Alban's, on Monday, Nov. 18th, 1844, and following days, at 11 o'clock, the whole of the varied NURSERY STOCK, comprising Fruit and Forest-trees, Evergreens, Ornamental, Deciduous, and American Plants of every variety, and about 3000 Standard and Dwarf Roses, consisting of the choicest varieties; 1,000,000 Quick and Oaks, of different ages; Seedling Beech, Ash, &c., Sea Kale, Asparagus, and Rhubarb, Dahlias, and Herbaceous Plants. The lots will be arranged to suit large and small purchasers. May be viewed one week prior to the Sale. Catalogues 6d. each, returnable to purchasers, may be had on the premises, of A. A. DEBARY, Auctioneer and Land Surveyor, St. Alban's; of the principal Seedsmen in London, and of the Auctioneers, Leytonstone, Essex.

AMERICAN NURSERY, KING'S ROAD, CHELSEA.

TO NOBLEMEN, GENTLEMEN, NURSERYMEN, FLORISTS, and Others.

MR. KIRKE will sell by Auction, on the Premises (late the American Nursery), King's Road, Chelsea, on WEDNESDAY, October 30, 1844, and following day, at Eleven for Twelve o'clock punctually, by order of the Proprietor, the ground being required for building purposes, the VALUABLE COLLECTION, consisting of [illegible] Rhododendrons, Kalmias, Azaleas, Laurels, Laurustinus, [illegible], Box (variegated and plain), Lilacs, Roses, [illegible], Evergreens, Weeping Trees, a quantity of large [illegible], Flowering Shrubs and Evergreens, Yuccas, Orange and [illegible], Standard Roses, &c. &c. (arranged in lots, and could [illegible] to suit the requirements of purchasers), [illegible] Greenhouse Plants, Bedding Plants, Cucumber and Melon Frames, Garden Rollers, Mats, Garden Engines, [illegible], Garden Chairs, Tables, Flower Pots, and other Effects of the Auctioneer, 20, Brompton-row, Brompton.

SPLENDID NEW GERANIUM—THURTELL'S OTHELLO.—The High very distinct and superb variety was raised by R. Cole, Esq., Devonport, R.N., Devonport, and is allowed by all who have seen it to be the greatest novelty that has been produced in Geraniums, possessing a new character, altogether unlike any other sort, which at once arrests the eye, and fixes attention upon it in the midst of all the finest modern varieties; it cannot fail to give satisfaction to all who buy it. Both shape is perfect, and the habit excellent.

A full description of this and other first-rate Seedlings raised by that celebrated cultivator, which have been exhibited at the principal Horticultural Shows this summer, and cut blooms of which obtained an extra prize at the Exhibition of the Royal Botanic Society, Regent's Park, on the 24 July, 1844, will be found in their Catalogue of New Geraniums, just published by LUCOMBE, PINCE, and Co., who possess the entire stock of all Capt. THURTELL'S flowers, and are now ready to execute orders with fine strong plants at very moderate prices.—Exeter Nursery.

The Gardeners' Chronicle.

SATURDAY, OCTOBER 19, 1844.

MEETINGS FOR THE ENSUING WEEKS.

Saturday, Oct. 26 Royal Botanic . . . . 4 P.M.
Friday, Nov. 1 Botanical . . . . 8 P.M.

WHAT is required WHEN CUTTINGS OF PLANTS ARE TO BE STRUCK, is a due adjustment of heat, light, and moisture. The first stimulates the vital process, the second causes the formation of matter out of which roots and leaves are to be organised, the third is at once a vehicle for the food required by the cutting, and a part of it. The great difficulty is to know how to adjust these agents.

If the heat is too high, organs are formed faster than they can be solidified; if too low, decay comes on before the reproductive forces can be put in action. When light is too powerful, the fluid contents of the cutting are lost faster than they can be supplied; when too feeble, there is not a sufficiently quick formation of organisable matter to construct the new roots and leaves with. If water is deficient, the cutting is starved; if over-abundant, it rots.

It is, then, the adjustment of these varying forces to the peculiar nature of the cutting to be acted upon that constitutes the art of propagation. It is this which theory cannot supply, but which depends upon skill and experience. If any part of the operations of cultivation can be called empirical, it is this. And yet the operator is not without rules to guide him in this adjustment; the misfortune is, that they are too general.

The softer a cutting, the quicker must be the excitement and application of the formative process, the more the light, the smaller the quantity of water. The more hard and woody a cutting, the slower will be the operation, the more feeble the light, the greater the quantity of water. If these conditions of new growth can but be preserved, all cuttings of all plants may be converted into new individuals.

The great enemies of the propagator, says Mr. Neumann, are rotting and drying; for this reason cuttings are preserved in the midst of a temperature and humidity always equal, the evaporation of the soil is hindered, and the perspiration of the cuttings is prevented.

Heat, light, and moisture being thus shown to be the agents to whose assistance we must look for success, and by whose mismanagement the hopes of the gardener are ruined, it is of the first importance to determine how each can be best and most efficiently controlled.

And first of heat.

We know that plants are distributed over all parts of the habitable globe; that in neighbouring countries the species are nearly alike, that distant countries are clothed with vegetation of entirely different kinds, and that the distinction in the vegetation is in proportion to the distance of the countries from each other. There is not, perhaps, a dozen species in Normandy that do not grow wild on this side the Channel; there is not a dozen species common to England and Bengal. Species, in fact, are in general limited by similarity of temperature, and cannot exist beyond such limits. One of the first considerations for the propagator, therefore, is what amount of heat is natural to a species during its season of growth. With less than that it is hopeless to make cuttings grow. It is only when plants strike freely that the natural amount of heat is sufficient; in general they require more. The amount of heat found in their natural climate may be enough for them to grow in; but a greater degree of excitement, by means of a higher temperature, will be demanded by them to strike root in, when cut up into the fragments called cuttings. A Willow-cutting stuck into the open ground will strike root, but it does so much faster and more vigorously if placed in a hotbed. A Whitethorn cutting in the open ground will not root at all; in a warm propagating house, it will do so readily; and, to reverse the illustration, cuttings of tropical plants, which naturally enjoy a very high temperature, will perish if it is reduced, and will only put forth roots when it is raised considerably above their natural standard. Thus Mr. Neumann maintains that Nutmegs, Cinnamon, Mangoes, &c., will not succeed unless in a temperature of about 100° Fah. That degree of heat again, would be fatal to greenhouse plants.

But it is not the temperature of the atmosphere that requires to be maintained above that to which plants are naturally subject; it is the soil that must be warmed. The first object is to obtain roots; those organs once formed, leaves will follow. The vital action which causes the production of roots is, in the first instance, local; roots are produced by the development of the cellular matter of the underground part; that cellular matter requires to be stimulated by unusual warmth; but the necessary stimulus cannot be communicated by a heated atmosphere: it is the warmth of the soil in which the cellular matter lies buried that must be secured. Unusual warmth of the air would have the effect of stimulating the buds, and would cause a premature appearance of leaves, which would be anything rather than conducive to the success of a cutting. If soil were to be kept at 33°, and the air at 84°, leaves would form, but no roots would be emitted under ground, however skilful the operator; and then, unless roots were thrown out above ground, the cuttings would speedily exhaust themselves. On the other hand, if the soil were kept at 84°, and the air at 33°, leaves would certainly be formed as soon as the roots had struck out, although in a pinched and shivering condition.

A proper degree of *bottom-heat*, then, is the first point for consideration, for all other processes are subservient to that fundamental requisite; and the rule is, that it should always be higher by several degrees than that to which plants are naturally subject. Unfortunately we have very little evidence to show what that is; but a rough estimate of it may be formed by regarding it to equal the mean temperature of the summer: hence the great value of good meteorological observations to gardeners. Suppose, for example, that it is required to strike a cutting of some plant from Algiers, and that the mean temperature of the summer there were 70°—which is, we believe, about the truth—the safe course for the gardener to take would be, to plunge his cutting in soil warmed up to 75°.

It is very much to be regretted that no one should have as yet compiled a set of meteorological tables for the use of gardeners. They would be invaluable; and we live in hope that some public body will, ere long, take up the subject. Scattered through books, there is a vast quantity of evidence which, although imperfect, is of great value, but nobody knows where to look for it when it is wanted. If such a work were once compiled, evidence would quickly accumulate, for inquirers would learn what to observe. With that evidence, gardening would assume more and more the condition of a science; for there is no doubt that a correct knowledge of the heat, light, and moisture of different climates is, next after the laws of vegetable physiology, the surest guide to successful cultivation.

The action of light and heat we shall consider on the next occasion.

Now that Providence has blessed us with an ACORN HARVEST of unexampled abundance, do not let us throw away the advantage. The value of these nuts for pig-feeding, and for deer or poultry, is well known; but we doubt whether, in their natural state, they are anything like so nutritious as they would be with a little preparation. We know that Barley is greatly improved by being malted; because the starch which it contains is by that process converted into sugar. Why should we not treat Acorns in the same way? They, too, are full of starch, and if malted would exchange it for sugar.

All that it would be necessary to do is to moisten the Acorns, gather them into a large heap in an outhouse, and throw mats or sacks over them. In a short time they would heat, and begin to grow. As soon as the young root is an inch long the malting would be effected, and might be stopped by simply spreading the Acorns out to dry again.

We believe this has been done already to some profit; and at any rate it is quite worth the experiment, especially for cottagers, for whose pigs Acorns are always in such request. It costs nothing, and cannot do harm.

As the season for PLANTING TULIPS is rapidly approaching, we hasten to lay before our readers the translation of a work published by a first-rate Parisian cultivator. Our Tulip-growing friends will thus have an opportunity of seeing how far our neighbours on the Continent agree with us in the cultivation of this beautiful flower, and at the same time they possibly may meet with some information which may be of service in the future management of their beds, &c. We have made a close translation of that part of the work which describes the formation of the beds, planting, &c., and where the Continental practice differs from ours, we shall give our own opinions as we proceed.

For the bed, "an open situation," says the writer, "is chosen, facing, if possible, the south-east or south-west, and at least 15 or 20 feet from any walls. The soil is then excavated, forming a cavity about 17 yards long, 18 inches deep on one side and 14 on the other, and 3½ feet in breadth.

"It may then be filled in September or October with a friable substantial maiden loam, which has been previously passed through a coarse sieve. The bed must be raised two inches above the surface on the side where the bed is 18 inches deep, and 6 inches on the opposite side, where it is 14, thus forming an inclined plane.

"By this means the florist can see at a glance his whole collection, and without confusion inspect them individually. There is also another advantage gained by giving the bed a gentle slope: drenching heavy rain can easily flow off, which otherwise might stagnate, and by soddening the ground cause serious damage to the bulbs."

Here we may observe that the usual method in England is to form the bed highest in the centre, so that in a bed of seven rows of flowers, which is the number generally adopted, the fourth or middle row is the tallest, and the others decrease in height on both sides, the first, or the row next the path, being shortest. By this arrangement, we obtain an equally good view of each side of the bed.

We do not, however, admire the plan of sifting or screening the soil composing the bed, as we are confident that bulbs do better in maiden loam, well beaten with a spade, in which the decayed turf is retained, than in earth or compost which has been passed through a sieve.

"If a second bed is formed," says our author, "care must be taken to make it parallel with the first, and exactly of the same dimensions. It should be separated from it by a path four feet wide, and its slope ought to be in the opposite direction, that is, the two beds ought to incline one towards the other to produce a more beautiful effect. In order to supply the requisite nutriment for the support of the bulbs, which when grown for a length of time in the same soil become foul and degenerate, the person who during fifteen years has had the whole management of my Tulips, changes the soil composing the beds every two years; and to obtain as fine a bloom the second season as the first, he spreads in July or August a quantity of night-soil, in a semi-liquid state, so as to completely saturate the beds; after a month has elapsed, he mixes it well together, either by passing it through a sieve or screen, or by turning it over with a spade, even to the bottom of the bed, so that the whole may be equally enriched with this most excellent manure. If night-soil is not easily procured, well-rotten cow-manure, in the proportion of one-eighth, may be added to the soil composing the bed."

Thus far, then, we have situation, the earth most proper for, and the form of the beds, with the manure usually employed on the Continent.

We consider cow-manure, in a thoroughly decomposed state, to be highly beneficial in the composition of a Tulip bed, and from experience we can say, that some of the finest blooms we ever had were when a thick layer of cow-dung formed the sub-stratum.

As for night-soil, we do not imagine that it is often used in the manner above alluded to, although we have seen its good effects on Ranunculuses, by being spread over the [illegible] when it was dug, in autumn, and washed in by the heavy rains usual at that period. Where fresh maiden loam cannot be procured, this might be tried, as we are sure that confidence may be placed in our author's experience. —*W.*

PRUNING FOREST-TREES.

Inutilesque falce ramos amputans.—HORACE.
With pruning-knife the useless branch he cuts.

I HAVE lately seen a long Article in the *Gardeners' Chronicle*, signed "W. Billington," containing some strictures on the management of my woods in the neighbourhood of Nerquis; and in support of those opinions the writer refers to a work entitled "*Facts and Hints*," published by him some twenty years ago. I think he estimates too highly the interest created by that work, in supposing not only that every one read it at the time, but that it made such an impression on the readers as to be still remembered. In his present letter, however, the hints may have been repeated—facts seem to have been forgotten. Mr. Billington's principles, reduced to few words, seem to be that the tree is supported from the atmosphere, through the leaves and branches, rather than from the soil, through the agency of the roots—a theory certainly very acceptable to the owners of barren mountain soil, but is anything to support it but the assertion of the writer. I do not feel disposed to deny that a tree with numerous healthy branches and leaves will increase in girth, more than one that has but few leaves, and those diseased. Here has been a confusion of cause and effect, and leaves the question entombed. Whether a wholesome discipline in removing a redundancy of branches may not tend to the improvement of the tree? I do not deny that leaves are necessary to the

well-being of a tree, and probably are to them what the lungs are to the human system; and every farmer is aware that plants with large and full leaves do not exhaust the soil in the same proportion as roots which have smaller leaves; but I cannot conceive that any one will deny that the various branches which Mr. Billington would so carefully preserve, must appropriate to themselves a certain portion of sap which would otherwise go to the nourishment of the parent stem. Why is it recommended to head down a tree that has been transplanted, but to keep down the sap within narrower limits? for the roots, from their recent removal, do not at once so fully perform their functions, and thus furnish but a feeble supply; and if the process of heading has not been adopted, for the first few years the topmost boughs seem dead; but as the roots begin to feed upon the earth, the vegetation becomes more vigorous, and at length the sap has been *driven into the extremities*, exhibiting in this process a convincing proof of the fallacy of Mr. Billington's theory—that it is by the descending sap that the tree is nourished. Mr. Billington likens the leaves to members, and the branches to families, and therefore the more they are multiplied, the more the nation, which he supposes to be represented by the trunk, will be enriched. I accept his premises to overthrow his conclusion; for, who ever thought a nation's welfare was increased by the merely multiplying the population, without providing means for their support? There seems something analogous in the human frame; by amputating a limb, we generally find that the patient becomes stouter. Mr. Billington then asserts that removing branches on their first appearance is calculated to make the tree puny, and he would wait till they are of larger growth. I should conceive the very reverse. As well might the practitioner delay the removal of an excrescence from the human body, until all its parts had become perfect through which it had drawn its nourishment. I had reserved a specimen, where the knife had never been applied, where all its natural tendencies had been uncorrected, for the edification of Billingtonian visitors, but I regret that it had died before Mr. Billington's inspection—I suppose with shame at its own uncouth structure; for when contrasted with its neighbours it exhibited the appearance of a deformed dwarf, beside a company of well set up grenadiers. Another point in which I differ from Mr. Billington in his mode of pruning:—He would foreshorten the branch which he intends to remove, instead of cutting it off close to the trunk, and thus making a second attack two or three years after; by this I apprehend he causes a greater wound, in consequence of the enlargement of the member to be removed, and creates a knot in the timber when eventually cut down. I do not think Mr. Billington is very certain as to his own mode of operation, or the extent to which it should be carried; for he speaks of encouraging branches, or removing them when necessary; it would have been more in character with one professing to teach, to have told us when that necessity existed. Mr. Billington then takes Mr. J. Scott Russell, an eminent engineer, to task, and questions the fairness of his comparing the trees at Nerquis with those growing in the neighbourhood, but under different treatment; but, with singular inconsistency, proceeds to compare them with the woods of other proprietors, planted in totally different localities, and, it may be, in totally different soils. The public, however, will judge which offered the fairest test. The concluding paragraph of Mr. Billington's letter leaves me in some doubt as to what *his* real views are; for, having throughout declaimed against pruning, he adds, "I protest against the non-pruning advocates;" and winds up by saying, "It is clear that we may regulate by skill and art the increase of the girth and elongation of the trunk to almost any proportion we please." This *is* precisely the object I have in view; and, to meet the crude and unsupported opinions of Mr. Billington, I would invite any unprejudiced person capable of judging, to visit the plantations in question; and in the mean time, having received some very flattering testimonies to their management, from scientific and practical men, I can, with perfect good humour, submit to the condemnatory remarks of Mr. Billington.—*W. M. Thackeray, M.D., Chester.*

ENTOMOLOGY.

ANISOPLIA HORTICOLA.—(*called the May-bug and Bracken-clock.*)—This insect is so great a plague in two of its stages, and has been so very troublesome this year, that its history will be well worthy the attention of the cultivator. When the Roses are in full bloom in May, these beetles sometimes do very extensive mischief to the flowers, by eating out the anthers and consuming the petals. I have also observed them feeding upon the leaves of the Bramble and Eglantine, and remember that some years since a host of them passed over a friend's garden at Thetford, and completely destroyed all the Roses, "leaving only the fibres of the leaves and on the flowers of those varieties that were in bloom. They flew like small swarms of bees; the produce [illegible] of Apples and Nectarines were destroyed by them in the same neighbourhood,"* and the young shoots were also occasionally defoliated by them. At another time they were so abundant on the Acacias near Twickenham, as to consume the foliage, and when the trees were shaken, they fell down like a shower of hail. In the middle of June they frequent Corn-fields and the surrounding hedges, about which they fly during the day, and enjoy the sunshine; they are also to be seen in Grass-fields, by hundreds, [illegible] flat, &c. and

ardes; and the sea-shore, where they often lie dead at high-water mark in considerable numbers.

Having deposited about a hundred eggs in the earth, the female dies, and the larvæ hatch and commence their attacks upon the roots of the Grass. Bouché says they live also on the roots of different flowers in pots, as Fragaria, Trollius, &c., which they gnaw off to the stem. It is, however, on lawns and pastures, that these larvæ commit the greatest ravages; by consuming the roots the Grass dies, the dead turf becomes rotten, and sinks irregularly under the feet, owing to the burrows which the maggots had made in the earth; and the rooks and starlings add to the disorder by pulling up the turf to feed upon them. These maggots were in vast bodies in Sept. 1839 and 1840 in Hants and Gloucestershire; and I received many letters with specimens this autumn, complaining of their devastations. It is stated that they are feeding three years, and they reside about an inch beneath the turf; but as winter approaches, they retire deeper into the earth; and even in November, when frost has set in, they have buried themselves a spade deep. From their large and uniform size at this season, I expect they are generally full grown and prepared to enter the pupa state, for which purpose they form cells in the earth, and in all probability remain in that quiescent state until the following spring, when the beetles emerge about the time the Roses flower.

Linnæus named this beetle Scarabæus horticola; Fabricius included it in his genus Melolontha, and it now forms, with some others, a group called Anisoplia.† In Norfolk it bears the name of May-bug amongst the farmers, and with the trout-fishers in the Lakes of Cumberland it is designated the Bracken-clock. A. horticola (fig. 2), is a pretty shining beetle clothed with longish hairs, dark on the upper, and yellowish on the under side; the head, thorax, and scutel, are of a bright green, often with a violet tint; the head is thickly and roughly, and the thorax finely and more sparingly punctured; the 9-jointed antennæ (fig. 3), are ferruginous; the club and palpi are piceous; the elytra are bright fulvous, with seven distinct and several obscure irregularly punctured striæ; wings ample; the underside and legs are black, with a green shade, the anterior being the stoutest, the hinder the longest. The first pair of tibiæ are notched externally, forming two distinct teeth in the male; the others are spurred at the apex; the tarsi are 5-jointed; the claws are unequal, the internal one being broad and bifid in the two anterior pair. Fig. 4, a fore leg of the male; the line shows the natural length of the beetle.

The larvæ are rather active, and can walk tolerably well, dragging their bodies after them; they lie, however, generally curved up in the shape of a horse-shoe; the head is deep ochreous and destitute of eyes; the antennæ are very distinct, slender, and 5-jointed; the mandibles are somewhat rust-coloured, black at their tips; the body is ochreous-white, with a few brown hairs, the apex of a lead colour when the larva is feeding, but like the rest when the stomach is empty. It has 6 longish legs on the breast, clothed with bristly hairs; they are triarticulate, the third joint short; the claws are small and acuminated, with one or two bristles on the sides. (fig. 1).

To kill these larvæ, water the Grass in the autumn with 1-10th gas liquor to 2-10ths water; it will do no mischief to the Grass, but will extirpate these miners. Where the gas-liquor cannot be obtained employ strong salt water. We should take advantage of mild weather in the spring to break up affected land, as at that time the larvæ are near the surface, and become an acceptable treat to the rooks, starlings, thrushes, blackbirds, robins, &c.; and even sparrows have been known to gorge themselves with these larvæ so that they were unable to fly. In the absence of such useful birds, pigs will be of service in reducing the brood of maggots; and where the Grass is only partially spotted, it is very beneficial to strew potash, unslaked lime, or other alkalies over the infested land before or after the winter season, which will restore the Grass to vigour, and, it is presumed, will destroy the grubs. Heavy rolling has also been successfully resorted to with a view of settling the undermined turf. If it be necessary to destroy the beetles, a cloth should be spread under the clustered branches previously to shaking them; and as this species flies in the day, this operation must be performed early in the morning, or in the evening.—*Rusticola.*

TRIP TO PARIS IN SEARCH OF AUTUMNAL ROSES.

Of the various floral improvements of modern times, nothing has probably produced such a beautiful change in the appearance of our gardens in autumn, or has been introduced with more striking effects, than the perpetual-blooming Roses. What can be more charming at this season of the year than to behold the rich colours of many of the Bourbon and Hybrid Perpetual Roses, contrasted with the more delicate tints of the Tea-scented sorts

* Gard. Mag. Bot., vol. xiii. p. 338.

off by their dark-green foliage, now that autumn has set its veil on many of Nature's earlier productions! I am an ardent admirer of the Rose, and my enthusiasm has, ere now, carried me to the Continent in the autumn month of June, in search of new varieties. Having this year caught the autumnal mania, I resolved to delay my visit till September, in expectation of finding the perpetual-flowering Roses blooming in greater perfection. In this I was not disappointed, and would here advise connoisseurs of Roses, who are accustomed to visit the grounds of the large growers in England, to do so twice in the year—in June for summer varieties, and in September for the autumnal sorts. I feel assured they would be well recompensed by, and highly delighted with a September visit. The Rose gardens then assume altogether a new feature; the summer Roses are gone, and the autumnal kinds appear in all their richness and beauty. True, the autumnal Roses bloom in June, but they seem to require the long dewy nights to bring out their flowers in trueness of character, and the difference is oftentimes so great, that the well-known Rose of June would scarcely be recognised when blooming in September. Thinking, however, that many lovers of Roses might not have leisure or inclination to travel so far in search of one object, which, among a multiplicity of affairs, becomes of small importance, I will endeavour to give an account of what struck me as most remarkable during my late trip. After having visited the grounds of the Hertfordshire growers, and collected the choicest of Rose's train there, I departed well pleased with what I had seen, and resolving to make further additions from foreign cultivators. Having reached the French capital, the first cultivator to whom I paid a visit was M. Laffay, the raiser of Madame Laffay, William Jesse, La Reine, and many other of our most beautiful Roses. I there saw Hybrid Perpetual La Reine in great beauty, and should pronounce it one of the gems of the season: the colour is pink, with a lilac hue, very glossy; the flowers are globular in shape, large, and very sweet. Another of his seedlings, Comtesse Duchâtel, is a Hybrid Perpetual of a superior kind. The flowers are of a rose-colour, with thick petals, closely set; Perpétuelle Indigo is a distinct variety, of a peculiar colour, to which its name relates; Hybrid Perpetual, Mrs. Crippe, a pale Rose, appears likely to become a profuse autumnal bloomer; Perpétuelle ponctuée, a bright Rose with white spots, is a very pretty variety. Of the four last mentioned, M. Laffay has, I believe, the entire stock at present, but intends selling plants of them this autumn. He has also a Moss Rose, Princesse Adelaide, of a pale rose-colour, blooming in corymbs, and said to be very handsome. The habits of the plants were certainly remarkable, having a degree of vigour quite foreign to the Moss tribe. Their season of flowering was past, but he said that the flowers were like those of Ornament de Parade, a well-known Gallica Rose; and other growers spoke well of it. Among others noticed here were Lady Alice Peel, Duchess of Sutherland, De Mars, Coquette de Bellevue, and Coquette de Montmorency—all Hybrid Perpetuals of recent introduction: the last-mentioned is in every respect a beautiful flower. M. Laffay is an enthusiastic cultivator of Roses, but a lover of fruits also.

To enumerate the various grounds visited would, I find, become tedious, and occupy too much space, having often looked through several in the course of a day. I must, therefore, arrange the varieties noted down as most remarkable, in their respective families.

Among the Perpetuals and Hybrid Perpetuals, were—Laurence de Montmorency, a free-flowering variety of a purplish rose-colour; Lady Elphinstone, rosy crimson, also a good autumn bloomer; Baronne Prevost, pale rose, sweet, and of an immense size; Comte d'Eu, a most beautiful carmine, but scarcely double enough, though apparently superior to Gloire de Rousmenes; La Bedoyère, a variety, of the character of Comte d'Eu, more double, and quite equal in colour; Marquise Boccella, delicate flesh, a decided acquisition among a class of Roses the prevailing colours of which are purple, and crimson; Prince de Galles, purplish crimson, a free grower, and seemingly well adapted for a pillar Rose.

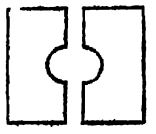
Among the Bourbons were—Charles Souchet, purplish crimson, of a very pretty shape; Comte de Rambuteau, of the same sort; Delille, a dark rose, finely cupped; Duc de Chartres, pale red, and a most superb Rose; Dumont du Courset, bright carmine, sometimes curiously marbled; Edward Defosse, a bright pink, shaped like Madame Nerard, first rate; George Cuvier, pale rose; Glory of Paris, another crimson variety, marbled with violet, and a fine rose; Impératrice Joséphine, pale pink, of a very elegant shape, blooming in corymbs; La Générale, reddish crimson, a seedling from Emile Courtier, and an estimable variety; Le Grenadier, vivid crimson, frequently tinged with violet; Madame Souchet, rose and blush marbled, a delicate and beautiful variety; Princesse Clémentine, violet crimson, good; Princesse de Modène, flesh; Sunset, bright purplish crimson, very fine; Souvenir d'Anselme, a lively cherry colour; Souvenir de Dumont d'Urville, crimson, changing to violet after expanding, and Souvenir de la Malmaison, a magnificent flesh-coloured rose.

Among the Noisettes were—Mrs. Siddons, in the way of La Pactole, but in its then state of superiority; Similar, a yellowish buff, but in appearance a weak grower; and Chrocatella, or Cloth of Gold, a Rose of yellow Noisette cast, of a paler yellow than I expected, and which does not appear to open too freely. It has, however, been an unfavourable season there for its flowering, and not being very plentiful it may not prove better than is anticipated.

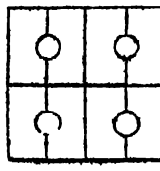
Among the Tea-scented, I noticed Adam, rose; the flowers were full and large, but not very abundantly pro-

dazed; Barbot, yellow, tinted with rose, a very pleasing kind; Boutrand, rose; Comte de Paris, flesh, one of the finest; Tea-scented Roses; Délices de Flandre, coppery red, very rich-looking; Josephine Malton, buffish yellow, of a beautiful form; Julie Mansais, sulphury white, the buds large and handsome; La Renommée, a whitish yellow, not new, but apparently little known; Madame Rousset, white; Marie de Medicis, rose, with fine outline, good and distinct; Moire, large full pale yellow, a superb Rose; and Safranot, a distinct and striking variety, of a beautiful saffron colour when first expanding, gradually melting off into buff. Some of these varieties I had previously seen in England, and in equal beauty of bloom; but others I there obtained acquaintanceship with for the first time.

Roses in Pots were numerous, but there were none remarkable as specimens of superior cultivation; certainly none that I saw were equal to those exhibited at the Horticultural Exhibitions about London, by Messrs. Rivers, Lane, Paul, and others; nor is it, perhaps, right to judge them by such a standard, as they were not grown to show what could be done with Roses in pots under good management, but merely as market plants. As such, the only objection to them by Englishmen would be the tall stems to which they were worked, and the little attention paid to their beauty. The head of the plant seemed to be considered the only part worthy of notice.—*W. Paul, Cheshunt.*



Home Correspondence.



The Plantation at Nerquis.—In reply to Mr Billington's statement, (p. 651), I beg to say that there were four persons—one an artillery officer—present, besides myself, when Mr. Billington went through the plantations at Nerquis. Mr. B. was very anxious that we should adopt his theory of the growth of trees, and because we could not agree with him in his views, he was evidently displeased, and everything was wrong afterwards. I have lived with Dr. Thackeray for a period of more than 40 years. I have at all seasons of the year during that time employed many hands to assist me in fencing, planting, draining, thinning, and pruning, without any interruption, and yet Mr. B. says, "I perceived that some parts of the plantation had been long neglected before they had been thinned and pruned;" "and the greater part of the Larches are good, but they are not what they might have been under a better system." This I beg to contradict, as I as well as the persons whom I have had under me know that it is not the fact. Mr. B. further remarks that, "the Oak and Ash are not fine trees, and evidently show signs of having been injured by the Larches not having been sooner thinned out from among them, and also from having been pruned to excess: one object is however gained, viz., tall, straight, slender trees, without side branches to a certain height, and which are fit only for ladders, rails, poles, or such like purposes." Now I appeal to my neighbours, and to all who have examined these plantations, whether this is not an unfair statement of facts. Mr. B. brings before us a few well-grown Ashes, planted probably in good soils, and in a better climate, but I put in a claim for a large plantation thinned and pruned with the utmost care for 30 years, as well as for plantations which I planted 10 years before that time for Dr. Thackeray's stepson; and I must repeat that they are the admiration of all (with the exception of Mr. B.) who have examined them. When Mr. Billington was leaving the woods, Dr. T. begged he would take a knife and show us in what manner he would prune an Oak about 10 or 15 feet high, pointing out a tree of that size. This Oak had a leader and four competing branches. Mr. B. then foreshortened four of them within two inches of the stem, and said that in two or three years he should cut them off close in to the trunk. We immediately said, "Why not do the same thing at once, and throw the sap into the leader, instead of doing so when the branches are thicker?" Upon this he began to theorise, and whilst he was doing so I was desired to cut the same branches off quite close to the stem. I at the same time said that all the trees had been managed in the same way, and that, had they suffered from this plan, the plantations must have been a failure, and that he would have seen a wretched collection of trees instead of the beautiful ones that were to be found all around him. I was then desired to take off not less than three, nor more than five of the largest and most luxuriant branches we could see descending the tree. Probably, in the course of this manner, one or more of the side branches will either be removed or foreshortened, and, from 40 years' experience, I am confident with the best success—experience being the best instructor in the matter of pruning. About a fortnight ago there were in the woods at the time a gentleman from Essex, one from Cambridge, one from Dundee, one from Huntingdonshire, one from Norfolk, and two from Chester, who evidently inspected the woods, and expressed themselves highly gratified with all they saw; having, as they repeatedly said, never seen such flourishing trees in all their lives. Below is an extract from Mr. Ponton respecting pruning; the mark is done now, in three or five years only, which is very different from the mode which I have been instructed to follow, as may be seen by referring to Mr. R. Scott Russell's letter, and others which have appeared from time to time in the *Gardeners' Chronicle*.—Ponton says, (page 566), "Pruning not only improves the form but increases the size of general weight of the tree." Page 566,—"If the first pruning took place when the plants were about 8 feet high, it might be necessary to displace two or, at most, three whorls of the lower branches; and two years further, two side more of the same description; after which intervals of three years might elapse between the prunings; never displacing more than two tiers at once, except more should prove dead." Further—"It will be observed that this method of pruning is calculated to grow the trees with a long conic head; and hence they would have every possible benefit from the atmosphere which the space allotted them can admit."—*Thomas Roberts, Nerquis.*

Pruning Forest-trees.—Mr. Billington deserves the thanks of all who feel any interest in this subject, for the manner in which he has (I may say) set at rest the question of pruning, as relates to the far-famed Nerquis plantations. The results of his inspection are precisely what I had conceived, from reading the various descriptive notices that have from time to time appeared in your columns. Dr. Thackeray is to be highly commended for his attention to his plantations, but if that attention proceeds upon a mistaken principle, it is detrimental where it might be highly beneficial. It is really marvellous how, at this advanced period of experience and observation, any one can proceed and act on the principle, that depriving a tree of its branches adds to or accelerates the growth of its stem; and yet it turns out that this is the principle carried out, according to Mr. Billington, in the Nerquis plantations, which several of your correspondents invited me to visit, in order that I might, from actual inspection, be induced to recall the opinions I had advanced in your columns. I desire no better authority than that of Mr. Billington; and, according to his descriptive statement, Dr. Thackeray's practice is merely Pontey out-done. Mr. B., in conclusion, protests against the "non-pruning advocates."—Who are they?—So do I. yet I will venture to say, that proper thinning, with no pruning at all, is preferable to the system followed at Nerquis. I have all along avoided the physiological question, which I think quite unnecessary in arguing the utility or non-utility of pruning. The term "reciprocity," which I have used, between root and branches, comprehends the whole, and the greater the degree of it, the more solid wood will be laid annually on the stem whether that wood be formed from ascending or descending sap, is practically of little consequence in the matter: the great point is to get it, and get it quickly, without saying anything about the *modus operandi*, which the authorities do not appear to have yet satisfactorily settled. The term "judicious pruning" is often used by your correspondents. Will any of them define it? How long is "judicious pruning" to continue? At what age of the trees is it to cease? Will Mr. Billington answer this, in reference to any of the plantations noticed in his last paper? It has occurred to me, that those who follow the severe pruning system(?) might save themselves some labour, by docking the roots a little. It would tend to preserve the equilibrium, and prevent the growth of useless wood, which only robs the stem.—*Quercus.*

Receipt for refreshing Raspberry and other Jams, long made.—Boil Blackberry juice till greatly reduced, add white sugar in the proportion of 1 lb to a pint of juice; mix the old jam with this syrup, and boil until sufficiently done. By this means the colour as well as the flavour is restored.—*P. T. C.*

Strawberries.—Most parties are, I believe, agreed as to the good result of placing stones under the fruit-bearing branches of Strawberries. In dry seasons they keep the ground around the roots moist, and in wet seasons they preserve the fruit clean. Now, I would suggest that a simple tile might be made of the annexed form, which I think would answer well, look neat, and cost but little. Let them be made about 12 inches square, preserving room for the average size of the stems. After a season in preparing new beds, the runners might be placed at equal distances, so that the bed would be entirely covered when required by these tiles, which would lay thus. A bed of 40 feet by 6 would require but 500, and their cost ought to be but little, as they could be made by any brickmaker, being merely flat tiles and scooped out. Is the idea a good one, and had the tiles better be glazed? A little additional cost is of no moment.—*M. A. S.* [On no account glaze them. If you have round pebbles at command, why not pave the ground with them?]

Monstrous Grapes.—The reading in a late Paper an account of a monstrous berry of a Black Hamburgh Grape, lately produced at Stover, in Devonshire, has induced me to mention that in a vinery at Dorfold Hall, in Cheshire, there is on the same variety a bunch in which there are three of these monsters; the largest of them measures in circumference 5 inches, the second 4¾ inches, and the third 4½ inches. The bunch itself probably weighs about 3 lbs.; there are several berries nearly as large in other bunches on the same Vine; they have very much the appearance of a Tomato.—*A Constant Reader.*

Culture of Vines.—I imagine that it is not out of place my bringing light from another science to bear on gardening, to say that the method of pruning Vines proposed by Mr. Hoare is, in my opinion, somewhat objectionable, as they must of course have a very limited range in their search for food. It may be said, Make the column large and all bud frequently with measure; but if the column be broad, the sap will not be given as desired, and however plump supplied with food, I should doubt the long life and vigorous health of a plant condemned to prison and solitary confinement; the roots will make constant efforts to gain liberty, and be repulsed; they will make search for food, and be driven back to the one spot: in that spot they will become thick, and the third dense; the soil around will be soon exhausted; and the new supply troublesome. If it be otherwise I shall be glad to know.—*A Reader.*—[This is assuming just that which nothing but experiment can show.]

Cucumber Melocoton.—In reply to Mr. Fleming, (p. 681), I beg to say that, although I made a mistake respecting the name of the Melon which I advertised, it is the true one sent out by Mr. Fleming's permission, as the advertisement of Mr. White below will prove. In the *Chronicle* for Oct. 7, 1843, it is stated, "By the kindness of Mr. Fleming we are again able to supply a few more packets of the Hoveslope Persian Melon at 5*s.* per packet." Mr. Fleming is the only person who had cultivated the Melon to perfection up to the time that he sent it out, and I cannot see how it can disgrace his name.—*J. Cuthill, Camberwell.*

Raspberries.—I strongly recommend the Beehive Raspberry as a prolific bearer of large fruit, and most excellent. I have a second crop of the B. Raspberry at this moment, on the new wood, as fine as those of the abundant summer crop.—*D. B. Greys.* [What *is* the Beehive Raspberry?]

Large Yew-tree.—There is in the churchyard at the village of Gresford, Denbighshire, a Yew-tree, which measures 30 feet in girth at the height of 4 feet from the base. The branches are in themselves large trees, and shade the ground to a great extent. It must be of incalculable antiquity, and it is not yet in a state of much decay, though it has for centuries perhaps attained its maturity. Other Yew-trees, in the same place, which were planted (as the parish-register records) in the year 1727, are, on average, in girth somewhat more than 4 feet.—*E. C., Pantyfocher, Gresford.*

Rose Catalogues.—The criticisms in the *Chronicle* lately, in reference to the dissimilar representations of the colours of Roses, are not wholly without cause, but perhaps, upon consideration, they may not seem so well merited as would appear at first sight. Rather than confine myself to the apparent error alluded to in my pamphlet on the Culture of Roses in Pots, I would take a general view of the subject; and in relation to the differential descriptions given by various growers, would hazard an opinion that the colours and appearance of Roses vary beyond degree. We believe that colours are deepened by the action of light, and numerous other circumstances also contribute in causing variations; for instance, the seasons—the different times of the seasons—the stage in which the flower is submitted for examination—the soil in which it has been grown—the health of the plant—and, above all, the different ideas of colours (without entering into the correctness or incorrectness of such ideas) maintained by different individuals. Now, with regard to the variation in the colours of Roses, see Indica Le Caméléon when just expanding—it is almost white. View the same flower a day or two afterwards—it is changed, and become a crimson! In fact, we may apply to Roses what the poet has written about a very different part of the creation:—

"'How slow its pace' and then its hue—
Whoever saw so fine a blue''
'Hold there,' the other quick replies,
''Tis green—I saw it with these eyes'
* * * * *
'Sirs,' cries the umpire, 'cease your pother,
The creature's neither one nor t other.
I caught the animal last night,
And viewed it o'er by candle light
I marked it well—'twas black as jet—
You stare but, Sirs, I've got it yet,
And can produce it'
* * * * *
"Replies the man, 'I'll turn him out
And, when before your eyes I've set him,
If you don't find him black I'll eat him'
He said, and full before their sight
Produced the beast, and lo! 'twas white!"

Prince Albert (Hybrid Perpetual) occasionally blooms of a vivid crimson, and often of a cloudy purple. T. Safranot appears almost saffron-coloured, but dies off a poor buff. The first flowers I saw of Lady Alice Peel (Hybrid Perpetual), now two years ago, were pink, and as such I retain a vivid recollection of them, although I have never seen them of that colour since. I have just gathered a flower of Bourbon Augustine Lelieur, which measures fully four inches across; but the colour is so different, that, had I not gathered it myself, I should have had some difficulty in naming it. Without multiplying solitary instances, if we view the whole body of Roses that bloom twice in the year, and compare the colours noted down in summer with their real appearance at this season, we shall find a difference. But supposing Roses to bloom alike at all times and in all situations, some indulgence may be claimed from the public, where 800 or 1000 varieties are catalogued and described. Perhaps the first step towards attaining accuracy of description is, to take down the colours on the spot during the season of bloom. This, doubtless, is done, although requiring a sacrifice of time and labour from the principals, which an extensive Nursery business will scarcely admit of. But, again, the whole varieties cannot be found in bloom at any one time, and the collection would require a second, third, or even a fourth looking through, which would be incompatible with other duties. The probable consequence is, some few are described from memory. Now, although such descriptions may not be perfectly correct, may they not be considered sufficiently so to guide purchasers in selecting? which is the only purpose for which Nurserymen's Catalogues are published.—*W. Paul, Cheshunt, Herts.*

Cows Tentaculata.—This Cabbage seems a wild and

straggling grower, and occupies a great deal of room. It is recommended in the *Chronicle* as a delicious winter vegetable. At present it shows no heart. A little more information about the nature, culture, and growth of the Tronchuda would oblige—*B. D. Greys.* [Its leafstalks and heart are used like Seakale. It is tender, and is *not* a winter Cabbage.]

Bees' Eggs.—At p. 638, Mr. Pettigrew finds fault with my reply to "A Lover of Truth's" queries respecting bees' eggs. I expect, however, that some apiarian readers think otherwise, and see more reason to complain of his statement that "queen bees lay only one sort of eggs." I may state that I possess some working bees' cells containing the brood of small drones, or males, which clearly show there is a difference in bees' eggs, and also that no alteration takes place after the eggs are in the cells. Indeed, how could the latter be? Some say by royal jelly; but that cannot change the sex of bees.—*J. Wighton.*

Large Pine-apples.—In reply to an "Admirer of well-grown Pines," who asks Mr. Mills the following simple questions, viz.—What has been the probable quantity of dung used to bring the fruit to maturity? and the probable expense for labour in applying linings? I would state that every good gardener can tell the quantity of dung required to work a small five-light pit—and rotten dung is always valuable in a garden; and the labour for working such a pit is not worth noticing. I will venture to say, if an "Admirer of well-grown Pines" could produce at his employer's table a Pine of the enormous weight of 15 lbs. avoirdupoise, his employer would, in all probability, make no inquiry respecting the expense of dung or labour employed, but would be glad to know that his gardener had the merit of producing, for the first time in England, a Pine-apple weighing 15 lbs. I should have been proud to have been the grower of so noble a specimen, which could only have been obtained under the most skilful management, without which all the expense that could have been bestowed upon its growth would have been of no avail.—*W. Taylor, Streatham.*

Public Parks.—It must be gratifying to all who desire to see the comforts of the middle and working classes attended to, to know that a public park is about to be laid out in the neighbourhood of Manchester. It is unnecessary to dwell on the health-creating effect and moral influence that such a place of public resort will have upon the immense population of that town, as it is well known that where public places of this description have been opened to the community at large, the beneficial influences have been beyond all calculation. Public parks not only improve the moral character of individuals, but also lead to habits of industry, regularity, and taste. By the public prints it appears that 21,000*l.* have already been subscribed for this park; but in the expenditure of this sum, much will depend upon the judgment exercised in laying out the grounds, to secure the advantages which we ought to expect from a place of public resort in the neighbourhood of that large manufacturing district. I am aware that few places of this kind are properly upheld, unless they are arranged in a manner that will enable the directors to pay at least some part of the outlay. We may have liberal subscriptions for the original purchase of the ground, but unless some method is adopted by which the ground may be disposed of, so as to supply a fund for upholding the park in a proper condition, it will, like many other places of the kind, except those in the hands of Government, fall to the ground. Public parks have recently been laid out near *Liverpool*, and in the improving neighbourhood of Birkenhead. Both these parks have been judiciously arranged; the confines or outside borders are laid out in villa grounds, which it is supposed will be sold for more than the original purchase of the ground, while the interior of the park is devoted to the healthy exercise and recreation of the public. It would be well to impress upon the attention of the managers of the proposed Manchester park, that some such arrangement as that just adverted to should be adopted. If it were laid out in such a way that one-third of the ground was disposed of for villa residences, I have no doubt but that, under proper arrangement and management, the ground so disposed of would not only pay ultimately for the original purchase, but would uphold the park in proper condition. It is not only a serious matter, but one that requires the greatest judgment on the part of the managers of this affair, to secure the services of those who are well qualified to advise and arrange a matter intended to benefit succeeding generations. I hope, therefore, that the directors will not lose sight of an arrangement which may enable them to have funds to uphold in strict order and regularity a park worthy of their justly celebrated town.—*A Friend to Public Parks.*

Bokhara Clover.—Noticed in a former Number of the *Chronicle*, I find a failure; the great drought of the summer may have caused this. It can hardly be said to have blossomed here. I purchased the seed as recommended, in order that my bees might feed on its flowers. It is a coarse large sort of Clover, and grows 3 or 4 feet in height.—*B. D. Greys.*

Irish Yew, &c.—It may be useful to state that I have raised many seedlings from the Irish Yew; some are three years old, but all evidently are the common Yew; and this may save others the trouble and time necessary for their development. The fine season has been the means of the double-flowering Peach and Pyrus spectabilis producing fruit—the latter in unusual abundance, which, when frosted, is nearly equal to the Medlar in flavour; and the birds—good epicures certainly—prefer them to all the other fruits in the nursery.—*W. G.*

Destruction of Mice.—Your correspondent "Nemo," who inquires how best he may destroy the mice with which he is annoyed, is recommended by one who is an old practitioner to proceed as follows:—In the first place, let him arrange his canaries (which at present must be greatly disturbed by the mice getting into their dwellings at night) on the walls of his room, so that they may hang in even rows; under each row of cages, and nailed close to the wall, let a well-planed and neatly-painted half-inch deal shelf be erected, sufficiently wide to project several inches beyond the line of cages, and let it extend the whole length of the room. It will be all the better if a beading or ledge run along the front of each shelf. By this provision, the greater part of the seed, so unsparingly scattered about by the birds, will be prevented falling on the ground, and so, the temptation offered to the mice, who are greedily fond of canary and rape-seed, will be infinitely lessened. The next step will be to reduce the number of mice, for where there is bird-seed there are sure to be mice: this is easy. Procure a few pennyworths of nux vomica in powder, and, with a small portion of it, mix thoroughly some bruised canary-seed and crushed Wheat; place this in a saucer in a corner of the room, and close to it a second saucer filled with cold water; then, just before retiring to bed, sweep the floor carefully, and remove the seeds, husks, &c., that may have fallen from the cages. This will prove a night of terror, for death will make sad havoc among the birds' enemies. Next morning let "Nemo," after collecting the dead and the dying, and burying them, nail flat pieces of zinc or tin over every mouse-hole he can find. This will prevent any effluvium that might arise a few days afterwards from the decomposed bodies under ground. The remaining mice, their suspicions being awakened, will now troop off. Should they at a future period return, let the former dose be repeated at bedtime, and the result will prove equally satisfactory as before. If a cat's services be required, let her be domesticated when quite a kitten: then, by the aid of a slight switch as a corrector, a positive familiarity may be created between Grimalkin and the birds—the latter exhibiting pleasure rather than fear when the former is present. Where cats are inmates, poison must not be used; for if a mouse be poisoned, and a cat afterwards eats it, her death too frequently follows. Some of my neighbours, have, I understand, been recently placing poison in their grounds for the destruction of rats; the consequence has been the ascertained death of eleven fine (and several of them very favourite) cats. This is to be regretted, and no person will suffer more from it than myself. Though I have a large collection of birds, the only weapon I bring to bear upon their sworn enemies, the cats, is a legitimate one, viz., a long whip, which is artistically laid on, *in terrorem*, as occasion serves. As "Nemo" has between 30 and 40 canaries, I would suggest to him whether, in such a case, it would not be advisable to appropriate one room, with a door at either end, to their entire use. All vermin would be thereby excluded.—*W. Kidd, New-road, Hammersmith.*

Societies.

BOTANICAL SOCIETY OF LONDON.

Oct. 4.—J. Reynolds, Esq., Treasurer, in the chair. Various donations were announced. Read—A General Description of the Botany, Climate, and Physical Geography of the Neighbourhood of Embleton, in Northumberland; drawn up by Robert Embleton, Esq., in illustration of a Local Herbarium of the District, collected for the Society by the same gentleman. The Description and Herbarium will remain at the Society as a valuable record of the present condition of the district.

ENTOMOLOGICAL SOCIETY.

Oct. 7, 1844.—Geo. Newport, Esq., President, in the Chair. A specimen of Tortrix rutilana was exhibited by Mr. Bedell—an insect new to the British Fauna.—Mr. Westwood exhibited a specimen of Lenopalpus striatus, taken in Leicestershire by Mr. Plant. Several new Coleoptera, taken in Chili, were exhibited by Mr. Canning.—Mr. Raddon sent for exhibition living larvæ from Potatoes and Turnips, which had this year been very destructive in his neighbourhood. Mr. Westwood stated that they were the larvæ of some species of Noctuidæ, probably an Agrotis. There was no other way of getting rid of these animals but by hand-picking.—The President laid upon the table a number of specimens of Lepidoptera, in which the legs had been reproduced after having been broken off. The reproduced legs were none of them of the size of the old legs. The legs were broken off during the larva state of the animal.—Several specimens of insects were exhibited from Captain Boys, sent from India; they were prepared in a peculiar way by placing the whole insect between very thin plates of talc.—A new Pausus-like insect was sent by Dr. Cantor—the Trochoideus amphora. It attacks the leaves of the Cocoa-nut trees, of which it is very destructive. Dr. Cantor also forwarded some notes on the habits of Arachnida.—Some notes upon an orthopterous insect, a grasshopper, which had the power of swimming on the water, were read, from Captain Boys. The Secretary observed that he believed this was the first instance on record of an orthopterous insect with aquatic habits. The President referred to the butterflies whose legs had been reproduced. At a recent meeting of the Society this subject had been discussed, and it had been supposed that reproduction would not take place in insects in which true metamorphosis took place, but this was set at rest by the result of his experiments. Although the legs and claws were always reproduced, the armature of the insect never was. The reproductive power of the insect depended much on the weather, as in moist, damp weather he found the wounds would not heal.—Mr. Harry Goodsir exhibited drawings of the condition of the parts in the reproduced legs of a species of Crustacea—the Cancer pagurus. The reproduction in these animals was effected by means of a gland. This gland was surrounded by a series of vessels which also accompanied the reproductive germ in the ovaries of the animal.—Dr. Lankester pointed out the importance of studying this subject in a morphological point of view. The reproductive cell of all organisation possessed common characters, which once obtained, we should find an easy expression for the countless variety of secondary forms which it exhibited.

REGENT'S-PARK GARDENERS' SOCIETY.

The adjourned meeting for the discussion of Morphology (see page 639) took place on Tuesday evening, Oct. 8. Mr. Reith, the chairman, directed the attention of the meeting to specimens of Rhododendron and Camellia, which, after having formed and set their blossom-buds, had produced leafy shoots from the same buds, in consequence of being improperly excited. He considered these as illustrations of the necessity of setting such plants out of doors in summer, to mature their annual growth.—Mr. C. Moore read some paragraphs from an article in the "Magazine of Botany," opposed to Morphology, which he characterised as being evasive of the true question. He then referred to specimens of Cryptogramma crispum, in which the fertile fronds are evidently a changed state of the barren ones, thus proving that the production of seeds on the leaves, as in Ferns generally, was in no way opposed to the doctrine. Allium scorodoprasum was next referred to, in a specimen of which the flower-stem at its summit bore perfect seeds, in the ordinary seed-vessels, seated on little pedicels, and bulbs springing into leaf at the base of these pedicels, and there attached to the stem.—Mr. O'Neill asked what was really meant to be established by Morphology, as apparently opposed to the established order of vegetation?—Mr. Maher said that Morphology, which strictly meant a "discourse on form," taught us to believe that all the parts of plants are originally alike, being produced by the vital action from the same original tissue, and, consequently, that any part of a plant, before it was developed, would have admitted of a different kind of development under the influence of exterior circumstances. He said that buds, and bulbs, and seeds, the several offspring of the stem, the root, and the flower, were identical both in nature and office, as containing the vital embryo, and capable, when detached, of reproducing their kind. In the case of the Allium, the bulbs, being directly attached to the top of the stem, could not be confounded with the seed, which was produced at the extremity of a pedicel; and, that they were occasioned by some invisible impregnation before the development of the flowers took place, as had been assumed by some of the speakers, he designated as an idea wild in the extreme. He then took a summary glance of the progress of a plant. The root, when in its ordinary position beneath the surface, did not produce leaves, but little naked points of tissue, whose office was to absorb fluids; if the root were brought above ground, it would frequently produce leaves, and assume the character of the stem. In illustration of this, he mentioned a specimen of a seedling Potato plant in his possession, in which from the same point, near the surface, several runners were produced; some of these had been buried, and had produced both fibres and tubers; others had been exposed, and were leafy stems. The stem assumed many forms, and was different from the root, in being furnished with stomata, or breathing-pores; for, being exposed to the air, it had to perform the function of respiration, as well as of absorption. The leaves are composed of the same tissue as the stem, but developed in a peculiar manner for the elaboration of the sap; and they are furnished with stomata. Bracts are similar to leaves. In a specimen of Rhododendron, then before him, he said the true bracts, which should have been situated at the base of the bud, on a flat axis, were scattered along a leafy stem, exhibiting a gradual transition to a leaf, and in the axil of these bractescent leaves the flowers were produced, instead of assuming their natural character as a terminal cluster; the axis, too, was lengthened out, and would have formed a perfect leaf branch. The flowers that were produced were much altered from their usual character, but that they were flowers was plain, from their being coloured purple; and he could detect the filaments and stigma present.—Mr. Reid opposed the doctrine. In the case of roots, he mentioned that Bignonia radicans would produce shoots from the roots when covered. The case of a cone of the Larch producing a shoot from its apex, which had been laid before him, proved nothing; for the cone was filled with perfect seeds, in the usual manner, and these must have been the produce of flowers; therefore the shoot could not be a transformed flower. Viviparous Grasses, again, were simply illustrations of another means ordained in nature for the perpetuation of plants.—Mr. C. Moore said that he had observed the case of the Potato producing tubers and leafy stems from the same kind of runners, under different circumstances of exposure, and he thought this to be sufficient demonstration of the relation between roots and stems. The viviparous shoots produced on the Grasses were the result of a change in what should be the seed-bearing organs, the ovule having converted into leaves, instead of opening as a flower, and young plants being produced instead of seeds. In a subject comparatively new, and but little understood, it was most essential to do away with prejudice, or no satisfactory conclusion could be arrived at.—Mr. Fitzpatrick was not convinced by the series of articles in the *Gardeners' Chronicle.* The shoot of a Peach-tree,

produced from a leaf-bud, would, he said, produce flowers and fruit; but if there is no leaf at the extremity beyond the flower, both it and the shoot will perish; in this case, since flowers are said to be nothing but changed leaves, how is it that they do not elaborate the sap, and support the shoot? He had never seen proof that leaves performed the office of flowers, or the reverse. In viviparous Grasses, young plants are produced, but not flowers; and therefore the flowers not being present, can not become changed into leaves. In the case of the Allium, as seed was present, there must have been flowers, but probably the young plants were originated from seed, which had ripened prematurely, and had fallen to the position the plants now occupied.—Mr. Townsend denied that fruit would not come to maturity without a leaf beyond it. He knew of a fine crop of Grapes, where the shoots had been stopped at the bunch: in this case there was no leaf beyond, but the progress of the fruit was satisfactory. He wished to know, however, at what time the leaves of such plants as Peach-trees and the autumn Crocus and Colchicum, were transformed, as in these plants the flowers seem to precede the leaves.—Mr. Ayres forwarded several interesting specimens in illustration of the subject.—*M.*

Reviews.

A Descriptive Catalogue of Selected Roses, cultivated for Sale. By Thomas Rivers, Sawbridgeworth, Herts. Supplement to the same for the Autumn of 1844, together 22 pages.—*A Descriptive Catalogue of a Selection of Roses cultivated for Sale.* By A. Paul and Son, Nurseries, Cheshunt. 19 pages.—*A Descriptive Catalogue of Roses grown for Sale.* By H. Lane and Son, Great Berkhampstead. 16 pages.

These Catalogues are indispensable to the Rose-grower, and contain among them all the information people in general can want, except habit or manner of growth, which is only mentioned occasionally. Mr. Rivers divides his Roses into summer and autumnal kinds, and then subdivides each of these bands according to their real or supposed races. Mr. Paul's classification is by races only, but he separates the Climbing Roses from the others. Mr. Lane carries the classification by seasons further than Mr. Rivers, for he has Roses blooming—1, in May, June, and July; 2, in June, July, and August; and 3, from June till November; and each of them he subdivides according to their races.

We will not repeat here our criticisms upon the spelling of the names in these Catalogues, but content ourselves with recommending growers to adopt the nomenclature in Mr. Rivers's list, which, although not perfect (for example, p. 4, Schoenbrun for Schönbrunn, or Schoenbrunn), is much the best.

We extract Mr. Rivers's account of the Cloth of Gold, which has not yet come out in its beauty, except at the Bath Dahlia Show in September, where it was much admired; and the Prairie Roses, a new race of climbers, bred from R. rubifolia, an American trailing Briar, well suited for crossing, in order to obtain late-flowering kinds.

"*Cloth of Gold*, owing to an accident to the plant left for blooming, has not flowered here this season: I saw it, however, in the commencement of last June, at Angers, in great perfection: a strong plant against a wall had produced from four to five dozen of its splendid flowers; it had made vigorous shoots the preceding season, and every bud had produced its spike of flowers, the extreme outer petals of which were of a creamy sulphur, the inner a bright and beautiful yellow; its flowers were nearly or quite as large as our common Cabbage Rose. This variety will require a south wall in this country, and, like Noisette Lamarque, it must be established one year so as to produce some vigorous shoots; these the following season will give flowers from nearly every bud: these shoots must not, however, be shortened to any extent; four or six inches taken from the end of each will be quite sufficient. If it grows with extra vigour, so as to make shoots from twelve to fourteen feet in length, they must be trained in a serpentine form, or in any other mode, so as to avoid the necessity of shortening them. Like Lamarque, it will form a fine Standard, but like that it must either be removed to a north wall, as recommended for Standard Tea Roses in winter, or have its stem wound round with hay-bands, and its head protected with a prepared calico or other cap. Having introduced this Rose, I feel it my duty to give directions for its culture."

"*Prairie Roses.*—This is a new group of Climbing Roses, which promises to be of much interest. Mr. Samuel Feast, of Baltimore, U. S., has had the pleasure of raising the above-named varieties, from the seed of the single Michigan Rose, Rosa rubifolia; they are all of most robust and vigorous habits, making shoots in one season more than twelve feet in length. No. 3 is the most perfect and beautiful of the whole, giving clusters of flowers containing from twelve to twenty each; at first they are finely cupped; in a day or two they become imbricated, like those of the Duke of Devonshire. It seems to resist the hottest sunshine, and the flowers remain on the plant for a longer period than those with any other Rose: in wet weather, however, they are not at all bright in colour, as was the case with some that bloomed the past summer: this has been named the Beauty of the Prairies. My name is that given to it by Mr. Feast. No. 2 only occasionally gives autumnal flowers. No. 1, owing to most of the imported plants dying, is more scarce than the other varieties. All these Roses are perfectly hardy; they will form fine Pillars and pendulous Standards."

NOTICES of NEW PLANTS WHICH are EITHER USEFUL OR ORNAMENTAL.

Bellium bellidioides. Autumnal Bellium. (*Botanical Magazine*.) Compositæ. Pentandria Monogynia.—This plant is inferior in interest to few of the charming species and varieties of Asteris with which we are acquainted. Its habit is that of a shrubby-growing shrub, combining with strength of stem all the elegance peculiar to the tribe, and producing richly-coloured flowers about an inch long. Unlike most of its kindred, it commences blooming towards the end of October or beginning of November, and continues to flower through the winter till April. This feature, which is not the least interesting or useful, has suggested the specific name. It flowered in the Nursery of Mr. Low, of Clapton, in November last. Mr. Low obtained it from Mr. Cunningham, of Edinburgh. It is evidently of hybrid extraction. Although we are unable to state the exact source of the plant, yet we have seen others so similar in character at the Nursery of Messrs. Rollisson, Tooting, raised by Mr. Storey, of Isleworth, between E. impressa and E. grandiflora, that we can have little doubt of their common origin. In the management of this and all the stronger and more rapid-growing Epacrises there is one point to which we desire to direct attention. It is the common practice to employ nothing but moor-soil and sand in potting, and it is to this, perhaps, more than to any other individual error, that the lack of success is attributable. If a portion of loam and well-decomposed leaves be incorporated with the heath-soil and sand, much more luxuriant shoots will be formed, and the quantity of flowers increased; for the soil, being of a more open and porous nature, will prevent the lodgment of stagnant water around the delicate roots, which so often, by destroying these organs, perils the very existence of the plant. Flowering in the winter season, at a time when solar light is at its minimum, it becomes more especially requisite to place them in an open part, where other shrubs may not shade them; if this be neglected, the flowers will be inferior in richness and intensity of colour. A liberal supply of water and a slight degree of shade will be needed whilst they are making their growth; and a perfect circulation of air must be maintained at all times.—*Paxton's Magazine of Botany.*

Miscellaneous.

Fastolff Raspberry.—We have just received from Messrs. Youell & Co. cut branches of this Raspberry loaded with fruit in its different stages of growth. The fruit was not quite so large as some of the same kind which was sent us in summer, but it was well-flavoured, and very fine for the period of the season.

The Blackbird.—It is grievous to think that this bird, whose melodious voice gives such pleasure to the ear, and lends a charm to the ramble through the grove, must, for the sake of a little fruit, meet with the usual persecution. Its food, in spring and early summer, consists of the larvæ of insects, with worms and snails. The enormous number of slugs and snails, so injurious to vegetation, which are eaten by blackbirds, should at least save him, on the score of gratitude, from the general destruction. Well may the poet say—

> "Scare, if ye will, his timid wing away;
> But, oh! let not the leaden, viewless shower,
> Volied from flashing tube, arrest his flight,
> And fill his tuneful gaping bill with blood."

It were useless to prolong this list. In the utter ignorance that prevails of the benefits conferred by these beautiful creatures, with an equal ignorance of the food on which they subsist, it is hardly to be wondered at that many who venture into the gardens in search of insects, and other animals injurious to vegetation, alike fall victims to the indiscriminate slaughter vowed against every bird that approaches these precincts. In the little abode occupied by the writer, every encouragement is given to their presence. A neighbour once inquired how his lawn was so disfigured with worm-casts, whilst that of the writer's was so free? The answer was ready—"Leave off popping at the worm-feeders from morning to night, and your lawn will present an equally pleasant appearance." It is an agreeable sight in early morning to view the activity of the blackbird, thrush, starling, and others, vigorously tugging the struggling worm from his retreat, more especially if it should happen that the Grass is covered with dew. It is very true that some little fruit does fall to their share; but so grateful is their cheerful voice, and their interesting evolutions in search of food, deeply would the exchange be deplored that should deprive us of their presence for the sake of a little fruit, which in the hot season is, in all probability, as grateful to them as to the self-styled lords of the creation. And, last of all, let us remember that, as not "one sparrow is forgotten before God," it may well become us all to reflect whether, in the grand scheme of an All-wise Creator, these little creatures, sent undoubtedly for a beneficent purpose, although our imperfect knowledge may be unable to descry their immediate use, were not destined by Him to partake of some small portion of the abundance poured forth for the benefit of man.—*J. M.*

CALENDAR OF OPERATIONS

For the ensuing Week.

I.—HOTHOUSE, CONSERVATORIES, &c.

The old Blotia Tankervillia, as it was once called, is an excellent plant to force in winter, and should now be removed to the forcing-pit, where a brisk bottom-heat of from 80° to 90° can be kept up. Euphorbia jacquiniflora is unwilling to submit to much forcing at this time, but if it is checked now by being kept rather dry for a month or six weeks, it will flower a month earlier than its usual time. Old plants of Justicia speciosa and Eranthemum pulchellum always flower earlier than young ones—they should be ready for the conservatory at the same time with the early Chrysanthemums. The Hibiscus manihot makes a gaudy display through the autumn in the conservatory, and is best from seeds treated as an annual, like the Balsam; pieces of its roots potted now and placed on a shelf in the stove will make plants nearly as good as seedlings, and will flower two months sooner than seedlings, but older plants of it are more or less unsightly. Nematanthus longipes is a curious winter-flowering stove plant of the easiest culture, and well suited for the drawing-room or conservatory when in flower, as is also Centradenia rosea, which is from us in its way; this also flowers in winter and early in the spring. Achimenes pleta seeds freely, and no doubt will produce crosses; it is well worth saving on that account, as well as for the beauty of its flowers and the singularity of its foliage.

Conservatory.—In answer to an inquiry, I beg to say that I have already in the Calendar stated all I know respecting the most conservatory climbers, with their names, treatment, &c. I imagine that the Mandevilla is as hardy as the Calampelis or Bignonia scabra, if not as hardy as the common Passion-flower; 5° of frost has not affected its beautiful flowers in the least. The best way to insure the procuring of the true flower, for Bignonia jasminoides, is to ask a nurseryman to send a plant that has the remains of the flowering truss on it: as they always flower in the smallest pots, there can be no difficulty in supplying plants in this state, and they are very cheap. Every effort should now be made to keep up the gaiety of this house, especially if it is attached to a sitting-room, as all good conservatories ought to be. The Chrysanthemums will soon be in; we cannot profitably force them; we can retard some of the late ones by placing them under a north wall: strong plants only should thus be treated, and rough sticks should be placed against the wall over them, to support mats, which should be put over them in cold frosty nights. The best Pelargoniums to flower in October are the Jewess, King Rufus, Modelice, Isidorianum, and Sidonia: each of these will stand hard forcing without injury; after these the Alba multiflora comes in. Pelargoniums with sweet-scented leaves are very useful for mixing in bouquets in winter, and some of them should now be forced: every place has its rose-scented variety, but the true rose-scented one is very scarce—it is the best of them all; next to it is Coronarium, an old one with a stiff erect habit and small curly leaves; and then, perhaps, Prince of Orange and Lady Flora Hastings are the next best. A large leaf of Fair Helen does well at the back of a bouquet, but it is too powerful and terebinthine for some people. Jasminum grandiflorum makes an excellent climber in the conservatory, but is seldom to be met with as such. J. stellatum, ligustrifolium, biflorum, with the varieties of Sambac and some others, make good forcing plants for rooms, &c.; for this purpose their climbing habits should be checked by under potting, and by pinching off the points of the shoots when the parts are young; they will then form bushy heads and flower more freely.

Pits, &c.—The forcing-pits should now be in full operation to keep up a stock of flowering plants for the rooms and conservatory through the winter. All hardy and half hardy plants brought in for forcing should have a temperature at first of from 50° to 60°, to be increased up to 75° when more advanced; but as many plants will not bear such heat, and others will not do much good without a high temperature, there should be two distinct pits or divisions at least for this purpose. In large establishments many plants are forced in the stoves and early vinery; but to allow the management of these houses to be altered in any degree to suit forced flowers is no economy. However, there are many things that may easily be forced in this way. With a large stock of Chinese Azaleas some of them may be had in flower from Christmas till the end of May; the first lot should now be brought to a heat of 50°, or even 60°, if they were well forced last April, and if their flower-buds are prominent. The double Roman Narcissus is the first of the forced bulbs, and where they have been potted early in August they will now stand 60° of heat, and will be in flower by the end of this month. Hyacinths, that have also been potted before the middle of August, will now endure a good heat, and bloom early, without at all injuring the bulbs; whereas late potted bulbs are ruined if forced early; not but that they will flower well enough, but the bulbs are of no use afterwards.—*D. B.*

II.—FLOWER GARDEN AND SHRUBBERIES.

Out-door Department.

If there is one thing more than another which contributes to the high keeping of this department of a gentleman's establishment, it is finely-kept and perfectly smooth *turf*. So fastidious am I in this particular, that the gayest flowers, let them be ever so well managed, would not please me, if the turf which surrounded them was in any way defective—in truth, it is impossible to produce a harmonious whole if the turf which surrounds the groups of flowers is not in every respect perfect; and for this reason, at this season I make it a rule to reinstate every foot of bad turf that can be found in any part of the grounds. This is unquestionably the best season to lay turf, except under large trees, and in such situations it is better to delay it until spring, or the constant dripping from the rains of winter would materially injure it. However, fine turf will not please if it is not level: smoothness, according to Burke, is a concomitant of beauty; and therefore, for a lawn to be beautiful, it must be level, smooth, and perfectly clean. And there is yet another essential element of high keeping which should be attended to, where necessary, at this season; and that is, the levelling and adjusting to one regular height the edgings which surround the walks and borders. These two things, combined with good walks, will give a garden a highly-finished appearance, even though there be not a flower in it; and in a neglected or badly managed one, will do more to improve it than any other thing that I am aware of. Let, therefore, those who wish to improve the appearance of their grounds attend to these suggestions; and if they are obliged to employ a few extra hands to execute the work, they will have the gratification of giving employment and improving their grounds at the same time.

Herbaceous borders may be now regulated, reducing the large plants considerably, and preferring rather to leave the outside than the centre of the plants. Where the plants have not been regulated for some years it will be best to take them all up, manure and trench the border, and replant them properly.—*W. P. A.*

IV.—PINERIES, VINERIES, &c.

Pineries.—In the management of the Pines intended for fruiting next season, it should be a principal aim to keep the roots in as equable a state of temperature and dryness as possible. Variations in either of these points are most injurious during the dull months of winter, when we are deprived of so much of the heat of the sun. Means should be taken to do away with the necessity of watering the roots of Pines in the winter season, and for this end nothing more is necessary than to cover the surface of the soil in the pots about two inches thick with leaves or tan, taken out of the body of a pit where they have heated and been partially decomposed. It will be found in the spring that the roots of plants so treated have suffered less (if, indeed, they have suffered at all) than those which, owing to the surface being exposed to the air, have required water several times in the course of the winter.

Vineries.—Whenever a house is cleared of its crop it should be immediately put into working order again. The washing of the glass, making all necessary repairs, painting, and remedying defects, or making alterations in the heating apparatus, should all be done as soon as possible, not only that the house may look more creditable, and be in readiness for the next season, but also that decay may be prevented from spreading. All these matters should be conducted on the principle of the old proverb, "A stitch in time saves nine."

Peach-houses.—Wherever, owing to an over-luxuriant state of growth, the trees in the late houses are not ripening their wood well, they should be assisted by making slight fires during the day, when the weather is clear. When the leaves are all fallen, let the trees be pruned, washed, and trained, as recommended in former Calendars.

Strawberries.—It is now time to think of protecting Strawberries in pots and boxes from rain, and where there are many pots to be kept through the winter the following is a good way of storing them. Choosing a sheltered place, which, however, must be open to the south, drive in a line of stakes of convenient height and length, according to the number of plants to be stowed away, and in the direction of east and west. Nail some old boarding to these stakes, and then spread a layer of dry ashes, about three inches thick and 2½ feet in width, on the south side of the boards. On this lay a row of pots on their sides, with their bottoms towards the boards, and their rims

parallel with the outside of the layer of soiled. Fill in well between the pots, and also between the bottoms of the pots and the boards, with soil. Then proceed with another layer of ashes, and then another row of pots, and so fill you come to the top of your boards, placing every row of pots a little nearer to the boards than the row below it, so that when finished the whole may present a sloping surface to the sun. The whole must then be covered with mats, in the form of a coping, of sufficient breadth to protect the lowest row of plants from shining rains, and with a slight inclination to the back, so as to throw the rain off to the north side. If care is taken that the ashes be quite dry when put in, frost will have very little effect on the pots. This is a plan very similar to what is in use in many places, and one which we find to answer very well.‖

Rectify.—In last week's Calendar, under "*Pinetum*," line 7, for "The night temperature should not *exceed* 60°," read "The night temperature *for the young stock* should not exceed 60°;" and under "*Exeter*," line 9, for "If it was done last month," read, "If it was *not* done last month."—*G. F.*

V.—HARDY FRUIT AND KITCHEN GARDEN.

Trees.—Pay every attention to getting the wood of Peaches and Apricots well-ripened, by exposure, shortening, &c. Prepare for planting all kinds of fruit trees, by getting the ground in good order and suitably prepared for the different kinds. The sooner the trees are planted the better, as they will then make fresh roots before winter. In all cases, but more especially on cold stiff soils, it is advisable to plant on hillocks, a foot or eighteen inches higher than the surrounding surface. The trees will not grow so fast in consequence, and will require more attention in summer for mulching, but they will form short-jointed, well ripened, fruitful wood, which is the best preventive of canker, gum, &c., and will save the labour of resorting much to root-pruning.

Roots.—No opportunity should now be lost for getting Potatoes, Parsnips, Carrots, Beet, &c. out of the ground, and stored up in a dry condition. Potatoes may either be kept in narrow pits, with a little dry earth sprinkled among them, or in airy dark sheds, according as it is desired, either to have them with the flavour and consistence of fresh lifted Potatoes, or in as dry and mealy a condition as possible.

Routine.—We have seldom had a better season for late Vegetables. Full Cauliflower before it gets too large, and prepare a shed or pit to plant a quantity on the first approach of frost. French Beans are still doing well with a slight protection at night. Remove those growing in pots, where they can have the protection of glass; lay down strong growing Brocoli, so that the stems may be covered with earth; plant out Lettuces and Endive for spring use. If planted on the sloping sides of wide ridges they will stand better, damp being quite as destructive as frost. Take the precaution of securing a quantity either in pits or frames, or have the means of protection in readiness. Remove the leaves from Rhubarb and Seakale, that you intend forcing very early, and keep a look-out for slugs and weeds, both of which will be troublesome after these rains.—*R. F.*

VII.—COTTAGERS' GARDENS.

The beauty of most of the plants which enlivened the flower-border with gay blossoms in summer is now nearly over; all that remain to cheer us at this season are some late flowering Phloxes and the varieties of Chinese Chrysanthemum, which, in fine autumns like the present, are very ornamental, when tied up so as to show their flowers to advantage. Cut down the stems of all plants that have done blooming. The roots of Dahlias will survive moderately severe winters in the open ground, if protected by a covering of dry litter or Fern; but they do not flower so well, and on that account it is better to take them up as soon as their leaves and flowers have become blackened by frost. Leave about 6 or 8 inches of the stem attached to the tuber. They may be preserved over winter in any dry cool place where they will be free from frost. When the flower-border is dug and put in order for the winter, which should be done about this time, or as soon as the leaves have fallen from the trees, any plants that have become too large should be reduced, and such as are not wanted may be removed altogether. Let decaying leaves and other refuse be taken to the manure heap, which should be turned over occasionally, and covered in with soil: any drainings from it should not be allowed to be lost; they should either be thrown back over the heap or they should be made available for some useful purpose. As was recommended last week, as soon as the leaves are off fruit trees, and the ground sufficiently moistened, transplanting, where it is wanted, may be proceeded with. Advantage should be taken of dry weather for earthing up Celery. Late Pears and Apples should now all be got in without delay.—*J. M'H.*

State of the Weather near London for the week ending Oct. 12, 1844, as observed at the Horticultural Garden, Chiswick.

The highest temperature during the above period occurred on the 21st, 1852—therm. 72°; and the lowest on the 26th, 1841—therm. 26°.

Notices to Correspondents.

Bees.—*K. B.*—We have given as much information about Bees in the early part of this year that we must refer you to former Numbers for the information you search for. If that is not sufficient for the purpose, you had better study some treatise on bee management, such as Bevan "On the Honey-Bee."

Books.—*A. S.*—We are unacquainted with Wahlenberg's "Climates of England."——*F. T.*—Read De Candolle's "Physiologie Végétale," and either Endlicher or Schleiden's "Grundzüge der Botanik," or Adrien de Jussieu's "Cours de Botanique."——*H., A Young Gardener.*—Ingram's edition of Malcolm, Lindley's "School Botany" to begin with, and then his "Elements of Botany."

Fruit-trees.—*J. P. W.*—In the present season a considerable number of both Apples and Pears have rotted on the trees before the period of maturity for gathering. The decay has ensued from the puncture of insects.

Gardenias.—*Sigma.*—These will live in a greenhouse, or even out of doors in summer; but to have them in good health and beauty you must give them a temperature of about 60° in winter and spring, until the flowers are forming; remove them then into the greenhouse, and they will remain in beauty during the greater part of the summer.‖

Heating.—*W. H.*—Our experience is not favourable to earthen pipes for hot water: the joints break and let out the water. Neither do we advise you to use any kind of porous hot-water apparatus for pits in which plants are merely to be wintered; they are all too damp. The cheapest mode of keeping out frost from such places is either to make the walls of earthen banks and to cover them with hurdles and straw, or to build a common smoke flue, which might be constructed with 6-inch circular chimney-pots. We have already given some hints about very cheap boilers, to which we must beg to refer you. Of earthen boilers we have no knowledge. Good mortar answers perfectly for jointing common smoke flues. You will see that several of your questions are unanswered, because we do not recommend hot-water gutters or porous pipes for your purpose.——*Vapor.*—If you are inconvenienced by the escape of offensive gas from your Arnott stove, the fault lies either in the construction of the stove, or your management of it. Coke is the best of all materials for such a contrivance, unless you can get Anthracite free from slates, which we can never do. Perhaps your draught is bad; perhaps the joints of your stove are open; perhaps twenty things, which nothing but experience and actual inspection can remedy. We have used an Arnott heated by coke, for some years, without any difficulty when we manage it ourselves.

Insects.—It is particularly requested that specimens of the insects, with the affected leaves, &c., as well as queries, may be sent to Mr. Curtis, without which he cannot undertake to return answers.——*D. L.*—If you will send us the insects attacking your Silver Firs, and, if possible, one or two small portions of the parts inhabited by them, we will answer your questions. *R.*——*A. Alves.*—Thanks for your data regarding the Cherry-sing caterpillar. The minute flies are a species of Barbarus (vide Curtis's "Brit. Ent.," fol. and pl. 459). Did you breed them from the Onion roots? The large caterpillar will change to the pale tussock moth, called Laria pudibunda. *R.*——*L. R.*—Your Pears appear to be affected by insects, but we could find none in either of them. Should you be able to detect any maggots in the fruit, and will forward them to us in a quill, we may be able to advise you regarding a remedy. *R.*——The scale insects infesting the Rafflesia are allied to the Coccus Hesperidum. If you will turn to an article upon those affecting the Orange-trees, at p. 427 of this Journal, you will gain the best information we can give you upon this tribe of pests. The other specimens are also female Cocci, and those which you took for ants' eggs are the ova of these scales, which are nearly related to the Coccus Vitis. If they appear in any numbers the twigs should be cut off and burnt. *R.*

Names of Fruits.—*J. P.*—1, Court of Wick; 2, Easter Pippin; 4, Beachamwell; 5, Braddick's Nonpareil; 6, Fearn's Pippin; 7, Kirke's Lord Nelson; 9, Hollandbury; 10, Minchal Crab; 11, Gansel's Bergamot; 13, Crassane; 15, Napoleon.‖——*A Devonian.*—1, Belle of Bonne; 2, Uvedale's St. Germain; 3, Beurré de Capiaumont; 4, Glout Morceau; 5, Easter Beurré; 6, Catillac; 7, Chaumontel; 8, Ghogil.‖——*J. F.*—1, Vicar of Winkfield; 2, Beurré Diel; 3, Glout Morceau; 4, Passe Colmar.‖——*Sarah S.*—1, Court-pendu Plat; 2, Pearson's Plate; 3, Dumelow's Seedling; 4, Court of Wick; 5, Golden Reinette; 7, Beauty of Kent; 6, Court-pendu Plat.‖——*D. J.*—1, Yorkshire Greening; 4, Bedfordshire Foundling. Pears: 1, Comte de Lamy, a very fine specimen; 2, Bacon's Incomparable.‖——*C. C.*—3, Duchesse d'Angoulême; 4, Brown Beurré; 5, Passe Colmar; 6, 17, Easter Beurré; 8, 16, Bezi de la Motte; 9, 10, 13, 14, Glout Morceau; 19, Henri the Fourth; 10, Beurré Diel; 20, St. Germain.‖——*J. G.*—1, Ferro's Pippin; 2, Golden Pippin; 1, Brown Beurré; 2, Winter Nelis; 3, Beurré d'Aremberg; 4, Chaumontel.‖——*W. H. H.*—A wild purple Plum‖——*S.*—1, Brown Beurré; 2, Urbaniste.‖——*C. B.*—1, Kirke's Lord Nelson; 2, Parry's Pearmain.‖

Names of Plants.—*Anon.*—Gesnera discolor.——*F. W. W.*—A withered flower of some Hedychium.——*A. C.*—Trifoliacum dactyloides.——*A. M.*—1. A Gonolobus, apparently hirsutus; 2. Dracæna australis.——*H. W.*—1. Mahernia incisa; 2. Gompholcarpus frutiosus. They have no English names worth giving.——*R. G.*—Cattleya granulosa.——*E. C.*—You now see that we are right; for you cannot doubt that the leaf you have had from India is that of the same tree as your false Banyan.——*H. C.*—Oncidium Forbesii.——*J. P.*—Diplotaxis tenuifolia was once called Sisymbrium tenuifolium; Nicandra physaloides, once called Atropa.——*E. T. O.*—Probably Podocarpus excelsa.¶

Orchidaceæ.—*Orchis.*—An Epiphyte house should not be kept wet in winter. At that period the air should be comparatively dry; otherwise when are your plants to rest? There is no work on their special management except Mr. Lyons's, which, we believe, is not sold. As to woodlice, a score toads will soon rid you of them. We will take your concluding suggestion into consideration.

Pears.—*S.*—We have no record of the Beurré Diel having been grown to a larger size than the specimen you sent, which was 14½ inches round, and weighed 18½ oz.‖——*A. B. C.*—Of the Pears you enumerate, the Glout Morceau is the most proper for a south wall, if you wish fine fruit about Christmas; if you prefer a later supply plant the Beurré Rance.‖

Pelargoniums.—*Amateur.*—Take up your seedling Pelargonium and cut it back in the ordinary way; pot it in a mixture of sandy loam and peat in equal proportions; then place it in the greenhouse for the winter, and keep it rather dry. Make the tops into cuttings, and put them into small pots filled with a mixture of peat and silver sand, putting three or four cuttings round the side of each pot; afterwards place them in rather a dry airy part of the greenhouse, where they will be secure from frost. They will be fit for potting off singly in spring.¶

Pine-apples.—*A Constant Reader.*—To prefer eating the fruit in a green state is not common.‖

Roses.—*A Subscriber.*—The following will answer your purpose, viz.:—Aimé Vibert, Noisette, Corymbiflora, Jaque Desprez, Triomphe de Plantier, Madame Desprez, Bourbon, and Phœnix.‡

Seeds.—*A Constant Reader.*—Pack your seeds in canvas bags, and take care that they are kept in a cabin during the passage.

Seedlings.—*W. G.*—Your violets, having been packed loosely in a tin case, along with a piece of ripe Pear, have been pounded to pieces by the shaking of the post-bags. As far as we can judge from the fragments, the variety does not appear to be striking.

Transplanting.—*X. Y. Z.*—Move your Evergreen Oaks in the course of November. Dig a large hole; take care that its roots are saved as much as possible; throw well pulverized soil about its roots; do not tread it much down, but manage the hole with water so as to puddle it; secure it firmly to its place, so that it may not be rocked by the wind; and you will have done all that prudence would suggest. The quality of the soil does not much matter, if it is neither wet nor chalk.

Weeds.—*A Constant Reader.*—Poisoning weeds on a lawn is a task, if there is much of it, without doubt; but it is the best way with which to plough it up, sow the ground, and so renew it with the following grass-seeds, viz.:—Cynosurus cristatus, 4 lbs.; F. tenuifolia, 4 lbs.; Agrostis stolonifera, 2 lbs.; F. duriuscula, 4 lbs.; Festuca ovina, 4 lbs.; Lolium perenne, 4 lbs.; Poa nemoralis, 4 lbs.; Trifolium repens, 1 lbs., and T. minus, 2 lbs. These mixed together will be sufficient quantity to cover 1 acre of lawn closely in a short time.‡

Yellow Noisette Rose.—*Amateur.*—To flower this attend to the growing and perfecting the young wood during the previous season. Want of attention to this no doubt has been the cause of your blooms not expanding. The best way to proceed with your plants is, after they have done blooming, to shift them if in small pots into larger ones, but if otherwise, only remove a portion of the top soil and replace it with some very rich compost, then put them into a close pit, and keep them rather warm and moist, in order to cause them to grow vigorously; take great care, however, that they do not become drawn or get infested with insects. When they have made their growth harden them off (by degrees) by exposing them to the open air, and give them less water; afterwards place them in a northern aspect, and allow them to become rather dry, in order that they may ripen their wood; then rest the plants, and afterwards put them into a cold pit for the winter; give them but little water for the first month; but afterwards increase it by degrees; and when you take them into the greenhouse let them have but little heat or moisture, for a week or two. Six good Roses for Pots are Bougère, Fabvier, Napoleon, Devoniensis, Blair Sauvage, Bertiana.¶

Miscellaneous.—*J. Abell.*—The last week in this month, or the first in next, is the best time for moving Deciduous Trees. Those which lose their leaves earliest should be moved first.——*H. C.*—A Carnation is not a Picotee, but a distinct variety.——*F. T. O.*—You will find some rustic cottages at Ravenscourt, near Hammersmith; but if you wish to see them in perfection, you should visit those erected by the Duke of Devonshire, at Edensor, one of the entrances to the Park, at Chatsworth.——*A Constant Reader.*—We are unacquainted with the Patent Portable Suspension Stove. Any stove will do what you want, if it is not too small.——*Pinus.* Oak-bark decays very slowly, and is a very long time before it is fit to be mixed with soil. It is more apt to poison land than to improve it.——*W. Wood.*—If you wish to know how Botany can be rendered poetical, you should read Darwin's "Botanic Garden," and the "Loves of the Plants." We cannot compliment you on your success in attempting to do what is not worth doing.——*Q.*—We cannot recommend nurserymen.‡——*H. G.* will find information respecting the management of Gladioli given at p. 115, 1842. The cultivation of the different varieties of Lilium lancifolium is also mentioned at p. 591 of the same year.‡——*T. P.*—Keep your Fuchsias as quiet as you can in winter, by withholding water and keeping them cool. They must not, however, become absolutely dry. Do not cut them down until spring.‡——*S. S.*—Yes.——*Medicinals.*—No. I——*H.*—We will inquire about Burckhardt's "Quince," if you will give us the page of his work in which it is mentioned.——*Umbra.*—You must be joking. If in earnest, we can only say that we have no art to infuse life into dead things. The only means you can employ for covering your trees in winter with green leaves, is to induce fresh Ivy to run over them. That may, with care and skill, be accomplished in a few years. Ivy-leaf of another kind we cannot offer you.——*A Tourist* must give his name and address. We cannot insert statements about crops from persons we know nothing of.——*G. H.*—If you will send your address, we will answer you privately.——*R. F. B.*—We do *not* recommend you to emigrate to the United States, unless you are without an alternative. It is of no use to acquire property if it is not secure; and who can tell what will happen in the United States? If you do go, you had better pack your trees in bog-moss in a wooden chest. It is of no use going to the expense of Ward's case. We are unacquainted with the prospects of Adam's County.——*M. U.*—We will examine your communication with pleasure, and try what we can do—duly mulled it *shall*. We are obliged by your suggestions, which are sent to the Agricultural Editor.——*Arrow.*—Nonea roses is not much worth growing. Morlandia arvensis is a violet-flowered herbaceous plant, something like Honesty. The three handsomest Godetias are Lindleyana, viminea and quadrivulnera, provided the latter is grown in very poor soil. The Pea you mention is most probably the purple-podded, fancy.——*Dubious.*—Coral is not a plant, nor the production of insects, but the calcareous crust of marine animals called Zoophytes, whose nature you will find described in the "Penny Cyclopædia," or any such work.——*W. P., P.*—You will find a plan of a frame that will possibly suit you, given at p. 428, vol. 1843. If you build a span-roofed pit for winter work, it should face north and south.‡——*Agrestis.*—We believe the real wax and hardest of all woods to be Lignum-vitæ, the timber of Guaiacum officinale.——*A Subscriber.*—It will not harm your plant of Aloysia citriodora to divest it of its leaves now, for the purpose of drying it.——*J. M.*—In order to make your young plant of Goldsmithia glomerata bloom, you must give it plenty of light and heat.‡——*Katharine.*—Solidago pulcherrima is one of the latest plants in bloom; it is very pretty, but it is generally rendered unsightly by frost and wind; Aciis (Leucojum) trichophylla is tender; it is not a bee bleacher: most of the early flowering kinds of Allium are very ornamental. Bulbine bisulcata is a greenhouse bulb of little beauty. Tangier Pumitory is unknown to us. Hyacinthus pumilus, probably Scilla bruinlii of Haworth, is a very doubtful species. Cornelian Cherry (Cornus mascula) is a shrub, or small tree, producing numerous small yellow star-like flowers, in February, before the leaves. Ornithogalum fimbriatum is not very ornamental; it flowers in March, if planted in a dry situation. Corydalis bracteata is very pretty and dwarf. Leucojum hiemale is also very pretty. Ophrys vernus is handsome. Erica herbacea and carnea are very pretty in winter. Colchicum chionense is unknown to us. Roman Narcissus requires a dry, warm situation, and protection from wet in winter; it flowers in March. The best Roses for purging down are the less rampant growing kinds; much, however, depends on the time when the kinds are wanted to bloom; for a long continuance, China Roses are the best; for summer, Mosses are best; and for autumn, the Noisettes. In pegging them down nothing more is required than to make the soil rich with rotten dung, and to fasten the shoots down with strong pegs, about one or two inches long.¶——*Reverians.*—All the back Numbers for this year may be had.

SEEDLING FLOWERS.

Fuchsias.—*A. B.*—The seedling No. 1 has not surpassed the sepals; their simple clinging round the corolla, if this be the permanent character of the flower it is valuable. But the larger variety shows is nothing to distinguish it from many others.——3 seedlings, 39, 40, 49. None of these flowers possess sufficient merit to send out; they are pretty, but not equal to many light varieties exhibited this season.¶

Pansies.—*J. C.*—Your flower *Beauty* was totally destroyed by coming crushed in the box: it is a large flower of good form and substance, but the colour in the eye is not sufficiently uniform, and runs too much into the eye.——*Amateur.*—The bloom sent is a young and imperfect one. It is crumpled in some way, and will no doubt come larger and better; it is a promising flower, round, and of considerable substance.¶——*C. N.*—Your seedling is a large and fine flower, having a small white centre, with a well-marked eye, the rest of the flower uniform light mulberry colour; it appears to want a little more substance for so large a flower.¶

Reseedas.—*A. B.*—Your seedlings, though pretty, are not equal in size or marking to many varieties now becoming this season. Those which approach a yellow colour, as No. 2, we recommend you to save seed from, as it is probable some striking varieties may be obtained.¶

*** As usual many communications have been received too late.

SEED WHEAT.—Donnington, near Stow, Gloucestershire.—From the number of testimonials received of the extraordinary crops produced both this year and last, ROBERT BEMAN is induced to offer to the public his Red Cluster Wheat, which both seasons has produced 60 bushels per acre in several instances; and, having been grown upon old turf, and hand-picked before it was planted, it is beautiful seed, and perfectly clean. Price 7s. 6d. per bushel.

R. B. has likewise a small quantity of the celebrated Whitfield Red Straw White Wheat to dispose of. Price 8s. per bushel.

Orders, accompanied by a remittance or good reference, punctually attended to. Sacks marked 1s. 6d. each.

The Agricultural Gazette.

SATURDAY, OCTOBER 19, 1844.

MEETINGS FOR THE TWO FOLLOWING WEEKS.

Tuesday, Oct. 22.—Agricultural Imp. Soc. of Ireland.

Thursday, Oct. 24.—Agricultural Imp. Soc. of Ireland.

FARMERS' CLUBS.

Oct. 21.—Woolpit, Fairford.
Oct. 22.—Framlingham, Rayleigh.
Oct. 23.—Richhill-Castle, Down Ferry, Binfield and Walsham.
Oct. 24.—Debenham, Stoke Ferry, Hadleigh.
Oct. 25.—Gloucester.
Oct. 26.—Chesterton, Wickham Market, Yoxford.

WITH regard to the best practical method of effecting the general introduction and promoting the beneficial operation of the ALLOTMENT SYSTEM, we deem it desirable that the inhabitants of every rural parish should carry it out among themselves. The acquaintance which they may be supposed to possess with their own circumstances and affairs constitutes them the proper agents in the matter. Wherever it is proposed to introduce the system, a meeting of the inhabitants should be called, and a small committee appointed for the purpose.* This committee should obtain a list of such cottagers resident in the parish as are desirous of renting land, together with a detail of the circumstances of each applicant, stating his age, residence, the number and capabilities of his family, the name of his employer, the name of the owner of his cottage, the size of his present garden, the quantity of any land he may elsewhere occupy, the names of owner and occupier of land adjoining; with any other information that may be needed.

These particulars having been ascertained, it will generally, perhaps, be found best to appoint a sub-committee of about three individuals to superintend the carrying out of the system, subject to the supervision of the general committee. This sub-committee in forming their plans should lay it down as a general rule, to be deviated from as little as possible, that every allotment should be near to the cottage of its occupier. This is of great importance; for if it be far off much time will be lost in going to and from it, the manure cannot be so easily made available for it, and it is not, as it should be, under the tenant's eye. The disadvantages of such an arrangement are obvious.

The land should of course be obtained of as good a quality, and at as moderate a rent as possible. It should, however, be borne in mind that the system is not likely to be established on a wide and permanent basis, unless it is made the interest of *all parties* connected with it to diffuse and uphold it. The landlord, therefore, should have such a rent as will remunerate him for subdividing his land, and fencing off the allotments; and such a rent the labourer can very well afford to pay.

In some cases farmers might be induced to sub-let small portions of their fields which might adjoin the cottage of the labourer; and all parish land which can be rendered available for the purpose ought decidedly to be let in allotments.

It will be important for the committee to consider well the position which they shall take between the landlord and the allotment tenant. We think the cottager should hold his land directly from the landlord, and not from the committee. Under such an arrangement every cottager in a parish might become, through the instrumentality of the committee, a permanent occupier of a small plot of ground; the committee might then be dissolved, and the system would work by itself. The committee, therefore, should merely use its influence in procuring suitable land. In some cases, where a number of houses are congregated together, it may be desirable to subdivide a field, the owner of which might object to the trouble of receiving rents from a numerous tenantry. In such a case let a respectable man from among the tenants become answerable for the rent of the whole, collect and pay it in, a small sum per acre being added to the rent of the whole, and allowed him for the purpose of covering his risk and remunerating him. We see no objection to the adoption of such a plan.

The size of each allotment will of course vary with the circumstances of the case. Regard should be had to the age, strength, and leisure of the man, the number and age of the children, &c., and the size of his allotment should be proportioned to the capability of cultivating it which he is thus found to possess. We believe that an error is frequently committed in making these allotments too small. An able-bodied man, with a wife and four or five children, can easily manage half an acre of land, and in some of the cases which we have quoted much more was successfully and beneficially occupied.

We now come to the consideration of a point on which we believe erroneous views are frequently entertained—we allude to the regulations under which the allotment tenant should be placed. We think that the sole object which we should attempt to attain directly by means of these regulations should be the proper cultivation of the land and the punctual payment of the rent. We would not enforce any particular rotation of crops, but would merely stipulate, that a certain portion of the produce should be consumed on the land, and that the manure produced should be returned to it. Every tenant ought to be sure of receiving the value of any improvements he might effect in the land by deep digging or manuring, in the event of his being obliged to leave his allotment before reaping the fruits of them. A time for the payment of the rent should be fixed, and any minor regulations adopted which the special state of the case might require; but beyond this we should not be disposed to go. We would not attempt (as is frequently done) to enforce regulations as to general moral conduct. If a man were a good *tenant*, he should hold his allotment, if a bad one, he should lose it; and having provided for this, we would leave the improved circumstances of the individual to accomplish the change in his moral character which they are proved to be capable of doing. But we cannot believe that it is desirable to impose regulations on him *as a tenant* which it does not fall within the province of *the landlord* to enforce. Whatever may be the character of the labourer, he is entitled to the means of supporting himself and his family. To provide him with those means is to favour his moral improvement—to withold them, is to plunge him into the abyss of pauperism or of crime.

Since the allotment system has been so abundantly proved to be the fertile parent of such great advantages to every portion of the community, and since it is a system so easy of introduction everywhere, may we not call on every individual connected with the land of this country, as owner or as occupier, to promote its general introduction? Humanity on the one hand, and necessity on the other, combine to urge attention to the condition of depressed labourers, and the call of each will become louder and louder till their demands are fairly considered and met.—*F.*

* The introduction of the allotment system wherever it is desirable, is now provided for by the law of the land. An Act introduced by Mr. Cowper and Mr. Miles, and passed in the last session of Parliament, enacts that in any parish where it may appear desirable that the provisions of the Act should be adopted, it shall be lawful for any three inhabitant householders to deliver a requisition signed by them to the officiating Minister of the said parish, requiring him to call a meeting of the owners and occupiers of land, and of the inhabitant householders of the parish, to decide upon the adoption or non-adoption of the Act. This Act afterwards provides for the election of Field Garden Wardens, to whom the future proper conduction of the matter is confided.

WITHOUT entering, at present, into any detail on the most economical method of removing and consuming the various green crops now cultivated by the farmer, we have to submit to our readers the following figures, descriptive of a good plan of harvesting them.

Fig. 1.

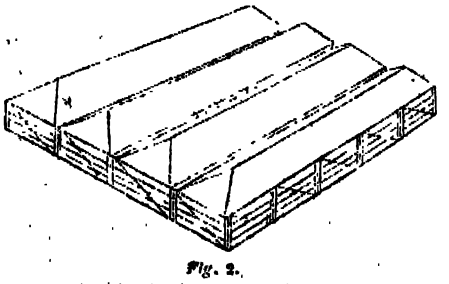

Fig. 2.

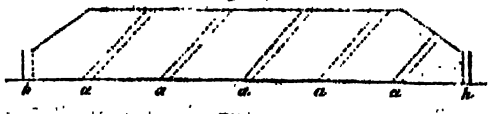

Fig. 3.

The first of these is a drawing in perspective of a series of heaps, of which Fig. 2 is the longitudinal, and Fig. 3 the transverse vertical section. They are made in the following manner:—Two rows of hurdles are placed upon a firm piece of ground, parallel to one another, and 9 feet apart. The interval between these is filled with roots, the carts bringing them from the field being backed between them, and tilted up at the proper place. The roots are piled up above the hurdles in a ridged or roof-like form, and are afterwards covered with straw, roughly drawn out as thatch, which is kept in its place by the weight of long poles resting upon it. At intervals of two or three yards faggots are placed in the centre of the heap, inclining backwards, and reaching from the ground to the roof (see *a, a, a,* Fig. 2). These act somewhat as chimneys, and facilitate a due ventilation of the heaps, thus hindering any tendency to heating or putrefaction in the roots.

When one heap is completed, another is built within a foot of it, the passage left being intended as a channel both for the egress of the water which drops from the thatch, and for the circulation of air. No security against frost, at the sides of contiguous heaps, is required, further than that which is afforded by the interlocking of the bushy eaves of their respective roofs. When, however, a series of heaps has thus accumulated, as in *Fig.* 1, a rough dead-wood hedge should be constructed around them (see section in *Fig.* 2), and the space between it and the hurdles, which may be 12 or 18 inches, should be loosely filled with straw.

Last winter, the weather during which, however, was not very adverse to the successful preservation of roots, we kept upwards of 1200 tons of Swedes, Carrots, and Mangold-Wurzel in this way, without losing any considerable portion by putrefaction. We shall take an early opportunity of returning to this subject.

THE ANOMALIES OF AGRICULTURE.

(*Continued from page* 690.)

LET those to whom this seems "a marvel and a mystery," and to whom the contemplation of the subject, from this point of view, is comparatively new, read a few pages of Evelyn's "Terra," and see the sort of stuff that passed for science with the literati of the Royal Society of his day; take this passage as a specimen.

"Those who have written 'de arte combinatoriâ' reckon up no fewer than one hundred and seventy-nine millions one thousand and sixty (1) different sorts of earth; but of all this enormous number, as of all other good things, they do not acquaint us with above eight or nine eminently useful to our purpose," &c.; and a little further on, in informing his "acute and noble" audience, where to find the best soil on their estates, he continues: "My lord Bacon directs to the observation of the rainbow, where its extremity seems to rest, as pointing to a more roscid (?) and fertile mould; but this I conceive may be very fallacious, it having two horns or bases which are ever opposite"——!

Such is the direction of the immortal author of the "Novum Organon"!—Such the reply and criticism of the most talented and admired biographer, physiologist, scholar, and naturalist of his day—John Evelyn! Come we now to the next epoch—still amid the annals of the Royal Society—the reading of Sir Humphrey Davy's lectures on Agricultural Chemistry, and from thence to the appearance of Liebig's works. Let it be borne in mind, that from the publication of the "Terra" papers to the reading of Davy's lectures, not more than 135 years had passed; from thence to the translation of Liebig's "Organic Chemistry of Agriculture and Physiology" (or, as the work might indeed with emphatic simplicity be called, *Quantitative Physiology*), there had elapsed but 15 years. Compare this period with that which has elapsed since "Adam delved and Eve span;" or take out the last five years alone, since the quantitative method of Liebig and the "practice with science" of the Royal Agricultural Society have shed their joint and kindred influence upon the art of tilling the earth; and then let us compare, if it be possible to compare, the growth of practice with the growth of science; and judge, if it be possible to judge, what the investigation of the physical sciences has done, how long it has been about it, and what, at an equal ratio of progress, it yet may do for that art which its empirical professors believed to be subject to no rules but those of their own ignorance, and, as ever was the case, disclaimed the infant science until in a few short years it grew to be a giant, and disclaims them. It is indeed a matter of almost startling curiosity, even to those who feel—what perhaps no one ought to feel—only a remote interest in such a subject as Agriculture, to mark its present existence on the face of—I will not say the earth, but I will say a single county—nay, a single parish or estate, of a country even the first in arts and civilisation, and knowledge and wealth, upon the globe. Look on this side of the hedge, you see every new appliance and discovery put into practice; the soil dry, deep, well-veriised, and rich, the produce nearly doubled, the very climate improved, and each element made a friend of, as its Maker intended, instead of being an enemy, through the sloth and negligence of man. Look now upon the other side of the same hedge, but on another farm,

"Like a mildew'd ear
Blasting his wholesome brother!"

The soil cold, dank, and unwholesome, with stagnant moisture, coarse in texture, shallow, foul, and poor; the produce scanty, starved, and blighted, the victim of every change, instead of the grateful recipient of each in their genial turn. Without moving a step the observer may

—— "look now upon this picture, now on this,
The counterfeit presentment of two brothers!"

Agriculture as it was, on the one hand; agriculture as it is in some places, and should be everywhere, on the other. It is a view which, whether regarded physically or morally, no one perhaps ever saw, or ever will see in such powerful contrast and relief, as that in which it is

presented to us. We enjoy a peculiar privilege—that of living in what geologists would call a Transition Period. We have, on the one hand, the self-satisfied and perfectly unsuspicious ignorance of the old-fashioned practical farmer, as he is now taught to style himself, in our fields: and on the other, the new-born and equally self-satisfied "closet conceit" of the theoretical writer, in our libraries. The man of science upbraids the farmer, because he is not a ready-made chemist, familiarly and practically applying the results of discoveries which the theorist has only just made, and is yet hardly sure of; and the old farmer laughs at the book-gentleman, and asks what he can know about farming? The strife has indeed begun—the strife that never yet was absent from the birth of infant science: for nothing great was ever born without the warning throes of parturition. Let Astronomy, Geology, Geography, Medicine, nay, let the purity of our Christain faith attest that! Can those who read now of conflicts whose very echo has passed away, between the struggling discoveries of master-minds with the prejudices of the age of which they were the pioneers, and usually the martyrs, doubt or wonder that science should be doomed still to encounter every opposition at the hands of those whom it most concerns and will most surely benefit? No! Man is still the same that he ever was: and the very individual who reads, with a glow of triumphant sympathy, of the personal or moral persecutions of a Socrates or a Luther, a Galileo or a Newton, a Columbus or a Park, a Hervey or an Arkwright, little thinks that he is perhaps himself helping to swell the war-cry of human prejudice against some martyr-science of his own day. It would seem as if truth, like refined gold, must go through the furnace seven times heated, before it is duly consecrated for the use and subservience of man. Opposition and prejudice it must encounter: if that opposition be weaker, and that prejudice more transient in our own age, let the praise be given to those whose earlier advance in the great warfare against them has cleared the way for an easier victory and a less hostile reception. It cannot be denied, however, that in respect of the sciences relating to agriculture, discovery has rather suffered from ridicule, neglect, and tardy adoption, than from any very formidable array of actual opposition. Tull and Bakewell were jeered and laughed at, but they survived to turn the tables upon the scoffers; indeed, a recent writer of great ability draws water from the rock, by a somewhat singular congratulation of his cotemporaries that so much should still remain to be done in the appliances of science to the art in question. "Formidable, indeed," says this writer, "would have been our position had the resources of art and science already forced our lands to their utmost capability of productiveness, leaving no alternative but dependence on other nations for the bread of even a small section of our people; but however strange the fact may be, it is no less historically true, that while the manufacturing and commercial portions of our people, by the application of the discoveries in modern science (especially in chemistry and mechanics) to their respective arts, have multiplied their wealth to a degree which it almost exceeds the power of numbers to calculate, the agriculturists alone have, till within a very short period, remained unconscious of the similar advantages that they also might derive from the application of science to the most ancient of all arts. * *

"Happily, the same concentrated force of scientific discoveries and mechanical inventions which had so marvellously augmented the productive powers of so many mechanical arts and manufactures, has also begun to accelerate the wheels of agriculture, clearly and obviously increasing the productive powers of the soil, in a ratio proportionate to the degree of scientific knowledge, and the amount of aid from improved mechanical implements of husbandry, that have been applied to co-operate with human labour; and no theory or prejudice can hope to withstand the influence of this salutary movement.* * *

"Had these improved systems (even as they now exist) been fully carried out over the whole length and breadth of the land, the capabilities of further increase might have been talked of as questionable; but it is notorious that to this hour there has been hardly any adoption of the greater number of these elements of amelioration—especially the fundamental element of thorough-draining—throughout the larger portion of the midland and western regions of our island; and to this very evil of retarded improvement we may now point for ground of hope, and confident assurance, that the supply of food may be increased in a degree fully adequate to any demand that may arise from our so formidably increasing population. The means of amendment are at hand; they are understood and practised by the more intelligent cultivators of districts which are now the most productive, and little more than half a century ago were the most unproductive portions of our island; and the education of the middling and lower grades of farmers in a knowledge of the systems adopted by their more enlightened brethren, seems to be the chief desideratum, in order to effect the general adoption of these systems throughout the empire."—*C. W. H.*

SKETCHES OF EAST LOTHIAN HUSBANDRY.

[We beg our readers to correct an error in the last Paper of this series. The average produce of Wheat in East Lothian was there stated to be 2½ quarters per Imperial acre; for this, read 26 bushels per acre.]

Barley.—This grain is not much cultivated in East Lothian, owing to the suitableness of the greater part of the soil for the production of Wheat. Barley, however, is found to pay well when a good crop can be obtained. It is cultivated to a greater or less extent on all kinds of land, and in every part of the county, but it is on the light Turnip soil, and in the upland district, where it is chiefly grown.

The principal varieties of this grain cultivated here are the Scotch or common two-rowed Barley and the Chevalier. The former has been grown in this county from time immemorial, and is considered to be better adapted than any other kind for light inferior soils and elevated situations. It also ripens at least a week earlier than the Chevalier, but the latter yields a much larger produce when grown on good land. The Chevalier is better suited for malting, and is therefore preferred in the low parts of the county, whilst the common Barley is that generally grown in the more elevated districts. The following are the results of an experiment made some time ago by Mr. Hope, of Fentonbarns, with the view of ascertaining the character and value of Chevalier Barley as compared with the Scotch variety. The soil was a dry loam of good quality. The seed allowed per Scotch acre was as nearly as possible fourteen pecks. The field was sown on the 25th March, the common Barley being all cut by the 8th, and the Chevalier by the 12th of August.

PRODUCE PER SCOTCH ACRE.

	Weight per bushel.	qrs. bus. pks.	Total per Acre. qrs. bus. pks.	Straw, per Acre, 16lbs. in the stone.
Chevalier Barley, best	53 lbs.	7 6 1	8 0 1	241

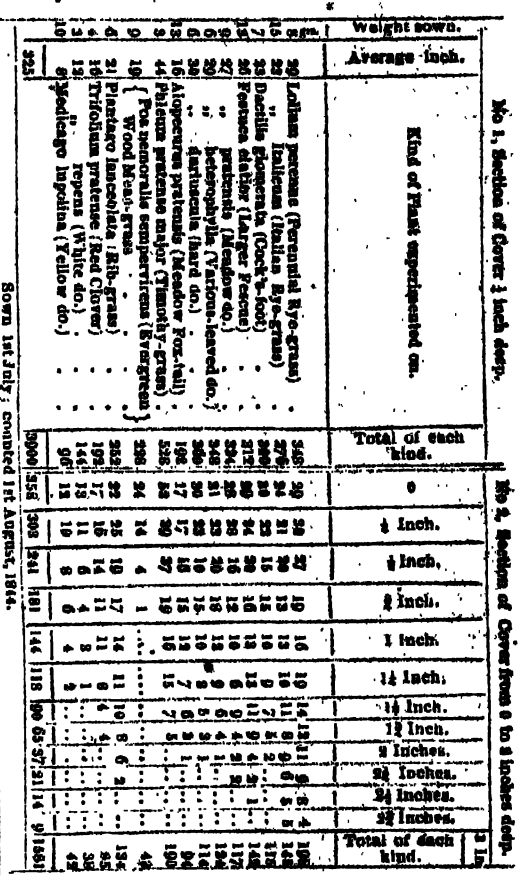
Common Barley, best	51	6 2 3	7 0 1	208
Do. Do. inferior	48	0 5 2		
Difference in favour of the Chevalier			1 qr.	33

The above experiment, with many others instituted for the same purpose, are given in detail in the nineteenth Report of the United East Lothian Agricultural Society.

Barley is generally sown after a Turnip crop, and also occasionally after a summer fallow. When the Turnips are consumed on the ground by folded sheep, which is a very common practice here, the land is ploughed immediately after the Turnips have been eaten off. This is generally about seed-time, and the Barley is sown as soon as the land is ploughed. But when the Turnips are removed from the ground during the winter and early spring months, the land is ridged up as soon after as it is convenient to do so, in which state it remains until the period for sowing the Barley arrives, when a seed-furrow is given to it preparatory to sowing. The grubber is now employed by many farmers with economy and advantage for the same purpose, instead of the plough.

According to the usual rotation of crops observed throughout the county, Barley is succeeded by Grass, either for hay or soiling as might be found necessary. The seeds of the Clover and Rye-grass are sown at the same time with the Barley, the general practice being, after the seeds of the latter crop have been sufficiently covered, and the surface reduced to a fine tilth by the process of harrowing, to roll the land with a heavy roller, and then to sow the smaller seeds either by the hand or with the broadcast sowing-machine, generally the latter. A single or double turn with the Grass-seed harrows usually completes the process, but a second rolling is frequently found to be necessary on strong clay land, for the double purpose of excluding drought and further reducing the surface if cloddy, as the Clovers are not found to succeed well on strong adhesive soils unless the land has been previously well pulverised and prepared for their reception.



Barley is sown from the last week in March to the middle of May. The quantity of seed varies, according to the quality of the soil and other circumstances, from seven to ten pecks to the acre. Five quarters per acre are regarded as a good crop, although five and a-half and six quarters are often obtained; 35 bushels, however, are reckoned a fair average crop per acre.

The medium weight of the common or Scotch Barley is about 52½ lbs., and of the Chevalier 54 lbs. per bushel; but there are many instances of well hummelled Barley weighing 58 lbs. to 60 lbs. a bushel. Barley is used to some extent on every farm. The hinds receive a certain quantity as part of their gains or wages. In many farms the horses get a boiled mixture of inferior Barley and Beans, two or more nights a week, throughout the greater part of the year. Almost the only kind of bread used by the hinds, and other farm servants, consists of a mixture of two parts of Barley with one part of Beans ground together; this bread, though sufficiently wholesome and nutritious, has a black and unpalatable appearance.—*T. Sullivan.*

WHAT IS THE BEST DEPTH OF COVER FOR GRASSES AND CLOVERS?

BY S. D. STIRLING, ESQ., of Glenbervie, near Falkirk.

The experiment shown in the following Table was made to ascertain the exact depth at which each kind of seed sown would grow most abundantly. In 1842, Messrs. Drummond and Sons, of Stirling, made a similar experiment at my suggestion, the results of which were exhibited at the show in Edinburgh; but, as garden experiments are laughed at by some, and as the difficulty still remained as to the treatment in the field necessary to obtain the best depth, I, in 1843, sowed 15 acres all over with red and yellow Clover, and a third part with each of the following Grasses in addition, viz.:—Italian Rye-grass, Pacey's Rye-grass, and Timothy. Two-thirds of the land intended for each of the Grasses was rolled after the Barley was finished. The Grasses and Clovers were then sown, and half of the rolled portion was bush-harrowed; the other half as well as the part not rolled, was covered in with Grass-seed harrows. I was surprised at the small apparent difference of the crop, but, on closer inspection, the shallower sown seemed thicker planted, and the deeper to have stocked more, from being thinner. It was with a view to settle this point that it seemed necessary to count the plants which would grow at each depth. The seeds were treated in the following manner:—Two boxes, 5 feet 10 inches by 1 foot, were filled with soil; No. 1 to within a quarter of an inch of the top; No. 2 to the top on the one side, regularly sloping to within 3 inches of the top of the other. They were then divided across by slips of wood 2 inches broad, so as to leave fourteen spaces of 2 inches by 1 foot in each box. The same weight of seed was sown in each box, the slips were removed, and the boxes filled to the top with soil. They were placed in a greenhouse for the first ten days, to prevent the risk of heavy rains, which would have crusted the surface. This may have caused the seeds to spring from a greater depth than would have happened under ordinary circumstances. The quantities sown as marked in the first column of grains of sixteen to the drop, were such as each ought to have produced nearly the same number of plants, had the seed continued as good to when sown and counted in spring, with the exception of the Timothy, of which nearly a double portion was sown from the difficulty of distributing so small a quantity equally. A quarter of an inch is too deep for the Poa nemoralis, as the Timothy grew more freely when scarcely covered.

The other information to be obtained from the experiment shown in this Table, beyond that for which it was made is, that it requires double the weight of Italian Rye-grass seed to produce the same number of *plants* that it does of common—that in this case at least, the Clovers and Fox-tail seeds, kept over a summer, would have been dear at half price—and that the total of the second column of No. 1 is less than the first column of No 2. I may also mention that, in a similar experiment tried this spring, 1844, and now growing here, the number of plants appear to diminish in the same proportion as shown in No. 2. They are generally most vigorous at three-quarters of an inch of depth, with the exception of Cock's-foot, Rib-grass, and red Clover, which do well to an inch and a half. Whether this difference arises from these depths being most suitable, or from the smaller number of plants, must be ascertained in a future experiment, by thinning them out to a single row. I would recommend all who wish to avoid disappointment, to prove all their Grass, Clover, and Turnip seeds before sowing, by sowing a small weight in a pot, and placing it in a warm situation, and counting the plants which come up, and they will find that 28 lbs. or 30 lbs. of Rye-grass seed may be cheaper than 18 lbs. or 20 lbs., though the price per bushel may be considerably more.

In 1842, when the Grass seeds were bad, and not to be procured of average quality, I sowed of some kinds three times the weight per acre which I had found sufficient in ordinary years, and with similar results. As I was much disappointed by following Sinclair's Tables of the number of seeds per lb., I subjoin a Table of the weight in grains of 16 to the drop, omitting fractions, which will give 100 plants of each, when the seed of

* See Col. Greenwood's Pamphlet, "The Tree-System."

commence is of the best quality which I have met with during the last four years.

6. Meadow Fox-tail.	4. Perennial Rye-grass.
5. Cock's-foot.	9. Italian ditto.
7. Meadow Fescue.	3. Red Clover.
9. Hard Fescue.	4. Yellow Clover.
1. Timothy-grass.	2. White Clover.

If the seed should prove of this quality I would recommend the following mixture to be sown for permanent sheep pasture :—

9 lb. of Fox-tail, which will give	1	plant to each	6	square inches
2½ Cock's-foot,	1	,,	16	of ground.
3½ Meadow Fescue,	1	,,	16	,, ,,
4½ Hard Fescue,	1	,,	16	,, ,,
4½ Italian Rye-grass,	1	,,	16	,, ,,
2 Red Clover,	1	,,	6	,, ,,
4 Yellow Clover,	1	,,	9	,, ,,
4 White Clover,	1	,,	4	,, ,,
6 Timothy,	1	,,	1	,, ,,
2 Rib-grass,				
1 Yarrow.				

Which will altogether give about two plants to the square inch. If the trial of any seed falls short of the number of 190, by any quantity, say an eighth, then 1 lb. must be added to the Timothy, ½ lb. to the yellow and white Clover, and so on in proportion. It may be asked why I recommend this mixture in this proportion? I answer that, after repeated trials, I have found it to succeed better than in any other. Why do I sow red Clover and Italian Rye-grass for permanent pasture? Because it is too expensive to seed the land sufficiently for the first year with the Grasses which sheep prefer, and because, in consequence, it carries more stock, and I have better pasture the following year. I cannot tell whether this is owing to the quantity of manure which the stock leaves, or to the food for plants conveyed to the soil by the Clover, from the atmosphere, or to the fact which I, as well as others, have noted (Mr. Kay, of Shiphaugh, Stirling), viz., that Grasses grow best when Clover is sown along with them. The Italian Rye-grass gives the earliest bite, and helps to occupy the space which would otherwise be filled with Daisies and other weeds. Why I sow yellow Clover? Because I sowed down a field with Grass, one half mixed with yellow Clover, and the other with white, and the sheep preferred that which was sown with yellow. Why do I not sow Rye-grass, Dog's-tail, Vernal, Poa trivialis, pratensis, and perennial red Clover? Because I sowed these and the others, which I recommend, separately, and put on a light stock of sheep early, so that they should not be compelled to eat that which they disliked. The Rye-grass will not carry through the stock necessary to keep it down in spring, and both it and the Dog's-tail were so much neglected, that I cut a full crop of hay off them. The Poa trivialis, Vernal, and pratensis, in a year or two became very unproductive, the two former suffering from drought, and the last forming a mat of which the greater proportion is uneatable, and which chokes everything else. The perennial red Clover, which I procured from a most respectable seedsman in Edinburgh, proved the common biennial. I therefore do not choose to pay an additional price, and run the same risk again. Besides, I see it neglected in my old pastures, where it grows naturally. For neat cattle I would recommend Rye-grass in addition, and for milch cows that the Yarrow be omitted, as I have found it, when in excess, to impart a disagreeable flavour to the butter.

I have the greatest pleasure in expressing my obligations to Messrs. Drummond and Sons, of Stirling, for their ready assistance in this and all other matters relating to agriculture.

Table of the greatest number of plants I have succeeded in raising, from 1 oz. and 1 lb. of the following seeds during the last four years :—

	No. of Plants per oz.	lb.		No. of Plants per oz.	lb.
Timothy	49,056	784,080	Perennial Rye-grass	12,251	196,020
Fox-tail	5,445	87,120	Italian ditto	5,445	87,120
Cock's-foot	9,801	156,816	Red Clover	16,433	261,360
Mead. Fesc.	5,801	112,011	Yellow ditto	12,251	196,020
Hard Fescue	5,445	87,120	White ditto	24,502	392,040

[*Communicated by Mr. Stirling, from the Highland Society's Transactions.*]

ON DRAINING HEAVY LAND.

I PERFECTLY agree with you that there is frequently too much width in drains, and too little depth; the mass of earth to be removed adding greatly to the cost. I will also admit that the small pipes alone (as mentioned by you, and as described by Mr. Parkes in his valuable communications to the Royal Agricultural Society), will after a time (a year or two) carry off one day's rain in three days. But this is only an imperfect mode of drainage, for several reasons. 1st. Because it is two or three years before it will act perfectly, instead of at once drying the soil, and rendering it friable. 2d. Because in dense soils (and to those my theories applied), the retention of water 48 hours longer than is necessary must be very injurious, by depriving it for so considerable a period of the atmospheric action. It acts like drowning, or soaking earth in water for two days, and must unduly expand its particles, absorb heat, and retain in degree that sodden characteristic which drainage is intended to remedy. I consider it an axiom that the friability of the soil will be in proportion to the rapidity of percolation; filtration may be too sudden, as is well enough shown by our hot sands and gravels; but I apprehend no one will ever fear rendering strong clays too porous and manageable. The object of drainage is to impart to such soils the mellowness and dark colour of well-drained rich and friable soil. That perfect drainage and cultivation will ultimately do this is a well-known fact. I know it in the case of my own garden. How it does so I am not chemist enough to explain in detail, but it is evident this effect is produced by the fibres of the growing crops intersecting every particle of the soil, which they never could do before draining; these with their excretions decompose on the removal of the crop, and are acted on by the alternating air and water, which also decomposes and changes in degree the inorganic substances of the soil. Thereby drained land, which was before impervious to air and water, and consequently unavailable to roots, to worms, or to vegetable or animal life, becomes by drainage populated by both, and is as great a chemical laboratory as our own atmosphere, subject to all the changes produced by animated nature. I apprehend that two days' stagnation of water would endanger either worms or roots. Mr. Parkes justly observed to me that worms act as assistant drainers, occupying the soil which before never contained any living thing; and it is through the innumerable conduits they make that water finds its way so readily to a small pipe at a considerable depth; but I consider, and must maintain my theory, that he who carries the falling water through heavy land in the shortest period is the best drainer, and will the soonest render such land equal to the best. To do this there must be in the drain a large area of porosity. The means of effecting it may vary as opinion varies; but the drain, to be economic, must have the largest porous area in the smallest possible space that will convey the water. I consider that the falling water descending uniformly through the whole surface, and mixing intimately with each grain or particle of earth, is far preferable, chemically and mechanically, to its forcing its way in streams towards the joints of the pipes, whilst the remainder is delayed, waiting a day or two, to take its turn in the same worn channel. For this reason I object to waiting for gaping cracks to make drains act, because it is quite possible the water may rush down such cracks from the surface, and leave considerable masses of intermediate earth unmoistened. The principal utility in drains is, in my opinion, to enable the earth to derive the full benefit of the various and all-important manures with which the falling water and renewed air are so amply charged. Another very considerable objection to the "wait-a-day-or-two" plan is, that the greater quantity of rain falls in the autumnal or winter months, when every day's ploughing lost is of consequence, economically and as regards the welfare of the ensuing crops. This alone should stimulate us to get rid of the obstructive water in a trice, for our autumns are never deficient in moisture, but the reverse. A small pipe will readily carry water when it gets in, but the question as to how and when it enters are subjects worthy the attention and experiment of your numerous and valuable agricultural correspondents. A comparative trial in various parts of one field would convince those who doubt. For my own part I am practically satisfied that my drainage is not too sudden, but that if it errs at all it is in not being quick enough, in such dense yellow soil. It may appear a startling proposition, but I think we are justified in inferring that drains in the summer season occasionally lay dry the soil below them. It is quite clear that if the porous portion of soil above the drain is deficient in moisture, earth below the drain must give up its moisture by capillary attraction, there being no impervious intervening substance between the upper and lower soil to prevent it.—*J. J. Mechi, 4, Leadenhall-street.*

Home Correspondence.

Allotments.—The subject of allotments of land, to be let at reasonable rents to persons of the labouring class, well deserves a prominent place in the *Agricultural Gazette*. It seems that the general adoption of the practice will much depend upon landlords; for, besides the usual restrictions in leases against underletting, the time is scarcely yet arrived when a majority of tenant-farmers would freely concur in the proceeding. When we read of 7*s.* or 8*s.* a week being the usual rate of wages for agricultural labour in Wiltshire, and when it is known that in districts of wealthy England, not 50 miles from the metropolis, a similar rate of wages prevails, surely something is wanted to remove a just cause of alarming dissatisfaction among an important class of persons, the value of whose labour—their only commodity for obtaining the means of supporting life—is thus depreciated. And while 7*s.* or 8*s.* a week is paid in some places, and 9*s.* or 10*s.* a week is paid for the same kind of labour in other places of a similar agricultural description, intelligent and impartial observers are not satisfied with the reason probably assigned for the difference—that, in the former case, there is an excess of labour, and not in the latter. But though allotments of land appear so desirable, and their advantage has in so many instances been so undeniably proved, strange cases have occurred—at least to the knowledge of the writer one case has occurred—where this advantage has been refused by labourers. In a parish chiefly agricultural, where the supply of labour has been fully equal to the demand, but not much in excess, and the rate of wages usually fair in comparison with some other districts, an owner of land, whose kind disposition is known, lately appropriated a field of good land for letting in allotments on fair terms to labouring persons, and only a small portion of the land was taken. Such cases are perplexing, and demand inquiry into their causes; and it might be inquired whether there was reason to fear that the farmers would regard the practice with jealousy, as apprehending (unfairly) that it might lead to neglect of their business by workmen. The diffusion of sound knowledge, and of good feeling and principles, will, in time, correct these evils in a country to which Providence has been abundantly favourable.—*E. Lister.*—There are many thousand acres in this neighbourhood, formerly reclaimed from the sea, which afford the richest pastures for cattle, but which require large and deep dykes to prevent them from being flooded in the winter, and in wet seasons. In keeping these large-water courses clear, a considerable depth of heavy soil is excavated. There being in this neighbourhood an inexhaustible supply of sea-sand, it has occurred to me that for cattle-yards, and for sheds in which cattle are fed, this sand, which is quite dry, and carried by the wind around the country, can be substituted for straw as litter for the cattle. It has several good qualities: a soft and dry bed for the animals, very clean, so porous as to prevent the urine and liquid matter of the manure from running off, which would prevent the expensive process of making tanks. It would check the escape of ammonia by constantly covering the wet bedding with dry sand, and it would immediately lick up any solution for fixing the ammonia; and when saturated with the excrements of the animals, would not only be highly fertilising on this account, but would be very beneficial in acting mechanically upon a clay and heavy soil, such as there is always being dug up from the dykes. Thus acting as a substitute for straw, the farmer can use his straw in the form of chaff, mixed with nourishing food, and thus passing through the animals, it will have lost none of its inorganic principles, but the same quantity of silex, &c., will be returned to the soil, as if it had been employed in bedding down cattle, and employing it afterwards as manure; and a much larger quantity of manure would be thus produced.—*Inquirer.* [We have known instances where sand has been used as litter for sheep; and in a year like the present, when straw is by no means plentiful, necessity will, we doubt not, induce many to try the plan, connected with which our correspondent points out so many advantages.]

How to Harvest Cabbages.—Allow me to remark that I have heard that, in Germany, some farmers, when they have a superabundance of Mangold-Wurzel leaves, half steam them, then pack them close in casks, slightly sprinkling the steamed leaves with salt by layers, which keep very well, and are eaten with much zest by cattle in that state. This might answer equally well with Cabbage leaves. Should it succeed, it would benefit the public generally if "Querist" will mention its success in the *Chronicle* at a future time.—*Elyséa.*

Two Crops per Annum.—I quite agree with your correspondent, "Cantab," that it is necessary for the English farmer to have two harvests in one year if possible, and I have often thought the Belgian system of growing a green crop upon the same land, and in the same season, that had previously grown Corn, a most excellent one, and worth our attention. I fear, though, it is impossible to introduce it here, the English climate being neither sufficiently early or certain to bring any kind of grain to maturity in time to grow the green food after it. Lord Lovelace's crop of Beans and Cabbages upon the same land approaches nearer than any other, but they neither of them grow well upon shallow soil. I have thought of trying Rye and Cabbages, but I have never seen the former harvested in this county at a period when I thought the latter would have succeeded had the attempt been made, which I confess it never yet has by me.—*A Norfolk Farmer, Fordham, Downham Market.*

[*Professor Johnstone's Catechism of Agricultural Chemistry and Geology.*—This Catechism is a clear and succinct arrangement of the rudiments of these sciences as far as they refer to agriculture; but I have some objections to the manner in which this manual is arranged. The first and most serious of these is—its catechetical form. I think that if the Professor had drawn it up in short and comprehensive sentences, without the form of question and answer, it would have been a far preferable book for the use of our schools. In this form it could have been made use of as a class-book for reading, and at the same time for instilling into the young mind the principles of those sciences of which it treats. Should questions be thought necessary, they could be placed at the end of each section, or at the end of the manual; but I would prefer the questions without answers, so that the pupil would be under the necessity of finding the answer for himself, and thereby giving him additional mental exercise. My next objection is the insertion of the instructions for the teacher in the body of the book. These should have been placed at the end, or on a separate sheet, so that they might only be in the hands of the teacher; but should the narrative form be adopted, they could be continued in the present plan without great objections. It would be a great improvement upon this manual if there were affixed an alphabetical list of technical terms, with explanations for the reference of the scholars, such as acid—how formed, and its component parts (that is, of any particular acid); carbonate, phosphate, nitrate, sulphate, &c.; and even very common terms, as calcareous, solution, dissolve, manure, &c., &c. In short, I would have this Manual of Agricultural Chemistry and Geology arranged as those of Natural Philosophy, published by the Scottish School-Book Association, which I consider superior models of a school-book.—*K., Denny.*

On Bones.—Of all the auxiliary and artificial manures yet found, bones hold the first place, both in effect and in certainty of result. They are applicable to most soils on which Turnips can be grown, and a failure is very rare. My own experience extends to twenty years, and only one failure occurred. My first trial of them happened in Northumberland, on a light sandy loam lying in patches on the outcrust of a friable sandstone, in the vast bed of clay on the coal formation. A grinding mill was attached to a flour mill driven by water; the bones

were ground in the forenoon and often sown in the afternoon; and if at any time laid in a heap, strict injunctions were given to spread them thin, in order to prevent heating. Very different is the treatment now, when means are used to produce that state. They were sown by a machine in a continuous stream, at the rate of 3 quarters to an acre; and in every application the crop of Turnips raised by them was superior to the usual quantity of the best prepared farm-yard dung: the following crops, however, were inferior, and a dressing of short dung was applied in the spring to bring them equal on the tested land. On cloddy soils the rutting coulter throws the soil wide, and it does not fall back again to cover the bones; a double mould board plough was made to pass quickly behind the sower, which threw fresh earth over the bones, and a roll followed. For seven years the crops were beautiful. On the stronger loams in Leicestershire the success was equal in every respect, the bones being sown in a cool state, and containing the portion of dust made in grinding them. On the ferruginous sands in Surrey, bones in the same state and quantity succeeded well; but in one year a partial failure took place on a loamy sand, fallowed and wrought after a crop of winter Vetches. The tilth was rather cloddy, but not too unfavourable. The Turnips brairded well: the plants rose after hoeing, and about half covered the drill, but never grew more. During the season the plants never showed the vigour usually produced by bones; the season may have checked their action; a cold, drizzling rain from the east prevailed at the time of sowing, and for some time after. The preparation of bones by mixing and fermentation has now become fashionable, and the sowing by drop-drill machines. My next experience was in South Wales, on soils of loose peachy loams. The bones were mixed with ashes and earths, and heated with hot lime, repeatedly turned and slaked with urine, suds, and water, and sown with a drop-drill machine at the rate of 16 to 20 bushels to an acre. In every case the crops were beautiful, but not superior to those produced by cool bones; which leaves undetermined the use or advantage of heating the materials. Some farmers mix the ground bones with earths, and produce, by their lying for a length of time in this state, a putrefactive preparation instead of fermentation, and it is found to answer well. No farmer who can command a sufficient quantity of vegetable manure, or farm-yard dung, will ever think of using any auxiliary; but many hilly and inland situations will hardly ever supply the quantity required, and consequently substances will be sought to produce the vegetables, which in their turn will yield the manure required. One very great recommendation of bones is the lightness of carriage; for if a farmer had large masses of vegetable manure at a distance presented to him, the cost of carriage would forbid their acceptance. The prime cost of bones is also less. In dry seasons rolling is essential, in order to compress the drills and the manure, to exclude drought, and retain moisture.—*D.*

Salt.—Several communications on the article "Salt," mentioned in pages 337 and 605, leads me to state that a more valuable substance cannot be purchased, and I would recommend all farmers not to be stingy in its use. How, I will ask, are those large crops of Potatoes produced both in Guernsey and Jersey, but from its general use there? having little to depend upon beyond the sea-weed found upon its shores. With regard to the quality of their produce, that is another question. Col. Le Couteur prides himself in quality—not quantity. He objects to the old jog-trot system pursued by all Jersey farmers; of course he pursues the English fashion, as practised in the Isle of Thanet, his heap of manure being composed of sea-weed, sand, and refuse from the farm-yard. Although I have but a small quantity of land, nothing do I prize so much as salt; I applied it during the dry weather to my Raspberries with complete success, filling in the crack and dispersing it everywhere. My garden and land has had 12 months' fallow, the land being in a desperate state of neglect, full of coarse Grass and as hard as a brick. Potter's guano (liquid) had no effect, but where I applied my pond-water with salt, I found wonderful effects; my Strawberries, though neglected, were fine through its use, although I regret to say that it was the cause of death to many poor frogs; the least quantity seemed fatal. When in the state of New York and also in Canada, I was surprised to find that it was their custom to give horses and cattle a handful or two of salt in their water to drink; nothing is such a treat to them, or so anxiously sought after. In several spots (for I have a variety of soil in a small compass) of a clayey nature, I am troubled with the Canadian Thistle, (I call it,) which roots very deeply. I have, after pulling it, tried salt, and I think it will be found to be the only remedy, as upon digging I perceived its effects.—*Verax.*

On Flax Seed as Food.—Conceiving this to be a truly important subject for the consideration of the farmers of the United Kingdom, I have much pleasure in referring to the subjoined account of the results obtained by the use of Flax-seed Compound, as communicated by Sir Charles Burrell at the recent meeting of the Arundel and Bramber Agricultural Association. I extract the following report from the *Sussex Express*:—"At the late meeting of the Agricultural Association here, Mr. Warnes advocated his system of box-feeding. He said that in Sussex, Turnips could not be grown as in Norfolk, but Nature had done much in giving them a fine pasture; in addition to that, they should use boxes for their cattle, such as many of them had seen that day on the Show-ground. With regard to summer grazing, he had found six stones of linseed, which would fatten cattle, was only equal to one of bar-which would not. By this means, and the use of boxes, three bullocks ought to be fattened instead of one; and this was no longer an experiment, for hundreds and thousands were now fattened in that way. The Chairman then read the following interesting statement:—'Account of six heifers, which were put into Sir C. Burrell's boxes on the 15th May last, to be fattened according to Mr. Warnes's system of summer grazing, but which had no compound till the 16th of June. Cost price of each—No. 1, 10*l.*; No. 2, 10*l.*; No. 3, 9*l.*; No. 4, 8*l.*; No. 5, 7*l.*; No. 6, 6*l.* Nos. 5 and 6 have been sold; No. 5 only has been killed; No. 6 is to be slaughtered in a day or two. No. 5 was sold to Mr. Page, at 3*s.* 10*d.* per stone. She weighed 75 stones, and therefore realised 14*l.* 12*s.* 6*d.*, or 7*l.* 12*s.* 6*d.* clear of the cost price. From this sum we deduct the cost of keeping. 1st. The Grass from the 15th May to the 9th September, when the butcher took the heifer away, or 17 weeks at 1*s.* 6*d.* per week. 2dly. The compound, from the 16th June to the 1st August, at 5lbs. per day, and from the 1st August to the 9th September at 14lbs. per day, amounting in the whole to 56 stones, which, at 7*d.* per stone, gives 1*l.* 12*s.* 8*d.*, or for Grass and compound, 4*s.* 10*d.* per week, or for the whole time, 3*l.* 4*s.* 10*d.*, which, with the 7*l.* paid for the animal, leaves a clear profit of 4*l.* 7*s.* 8*d.*, independent of manure — an important consideration. The cattle numbered 1, 2, 3 and 4 consumed 50lbs. of Grass each per day; Nos. 5 and 6, 35lbs. each per day. Two weeks they had Vetches. It ought also to be remembered that the Grass was obtained principally from waste ground, such as sides of roads, corners of fields, fences and gardens.'" The foregoing statement is confirmatory of those in my papers on this subject which recently appeared in the *Agricultural Gazette*, as exhibiting the results obtained by the use of the Compound at Hurkesley Hall. There is not indeed a more important article of food for the various domestic animals of the farm than Flax-seed. No expensive apparatus is necessary for testing its value, and it is with a view of inducing such farmers as have not hitherto used it to give it a trial, that I venture to direct their attention to the foregoing important statement of the results obtained by Sir Charles Burrell.—*J. Sproule.* [In the following extract from a letter of Sir C. Burrell's, which has lately appeared in the *Brighton Gazette*, another proof is seen of the excellence of Mr. Warnes's system of feeding:—"I have this week a second instance of the soundness of Mr. Warnes's system, in the sale and slaughtering of the second and least of the two Sussex 2-yearling steers, which weighed 72 stones 3 lbs. of very prime beef, being 4 stones 3 lbs. above the weight expected from her measure, and also above the butcher's expectation, who preferred buying by weight to purchasing according to the measured weight. The original cost was 6*l.*, and being sold at 3*s.* 10*d.* per stone, it fetched 13*l.* 18*s.*, a profit worthy consideration as derivable from Mr. Warnes's box-feeding system, with an expense of only about 30*s.* to 35*s.* for each box, if (as I conclude) a range of boxes be built. I am myself so entirely satisfied of the goodness and soundness of the system, that I have ordered a hovel to be converted into five more cattle-boxes, making 13 in all—a proof of my conviction of the correctness of all Mr. Warnes has advanced."—*C. M. Burrell, Knepp Castle.*]

Ichaboe Guano.—I have lately purchased 10 tons of Ichaboe guano; but in order to have it genuine I sent a sample to a chemist to be analysed. The analysis is as under:—

Water	148.31	Soda	50.00
Ammonia	105.41	Sulphuric acid	50.00
Organic Matter	146.36	Oxalic acid	85 41
Silica	59.84	Uric acid	68.09
Chlorine	26.10	Phosporic acid	99.12
Lime	95.20	Carbonic acid	16.04
Magnesia	46.10		1000.00
Potash	23.20		

Another chemist to whom I showed it pronounced it to be excellent; but told me that I ought to mix gypsum with it, otherwise a large portion of the ammonia would escape into the air. I shall be much obliged if you will inform me in what manner I can best apply the guano to Wheat, as I intend to commence drilling immediately. My farm consists of various soils, from a light soil on a subsoil, varying from a quicksand to a very stiff clay. I should also be glad to be informed whether a good dressing with clay would not improve the light soil, as it appears to require consistency and depth.—*A Constant Reader.* [All light soils will benefit by such an application. Guano is better applied to Wheat in April than in autumn. You can sow 2 or 3 cwt. broadcast, and harrow it in over the young plants; do not fear that you will injure your crop by so rough an operation. The guano should be sown in wet weather. Gypsum may be beneficially added if your soil does not contain a sufficiency of it, but it is questionable if it would tend to fix the ammonia in guano unless both were dissolved in water.]

Dibbling Wheat.—I am much pleased to see that some attention is paid to the poor and labouring classes; for in proportion as they are benefited, the community is benefited. I now allude to an article in the *Gardeners' Chronicle* of the 7th inst., in which it is stated that, by the allotment of lands in one parish, the poor-rates have been reduced from 5*s.* 3*d.* to 2*s.* 6*d.* in the pound, and parties who were living upon the rates are now contributors towards them. With such abundant evidence of the advantages of dibbling seed in preference to any other method of putting seed into the ground, it would be rendering a very great service to the public if some person of ingenuity would invent an instrument to facilitate this tedious mode of putting seed into the ground. I am of opinion that a very simple instrument, and at a very small cost, could be made which would enable two boys to do as much as four can do with the dibble now in use. I beg, therefore, to suggest my plan, and leave it with some of your mechanical readers to act upon it. A dibble, with a handle about 18 inches long, made like a shovel-handle, at the lower end of which should be fixed a plate and four dibbles, with flanges 1½ inch from the point of each (that being considered a sufficient depth to put the seed into the ground), the dibbles, by means of a spring-handle, being made to turn half-way round, would be an instrument of a kind which I conceive would be of very great advantage. If you think well to give it a place in your *Chronicle*, I hope it will meet with attention.—*A Constant Reader.*

Dairy.—Can you explain the cause of the strong bitter flavour which is perceptible in the cream of some dairies at the present time, and is said in the north of England to occur occasionally in different places? The bitterness is not to be perceived in the milk, nor in the cream till it has stood for one or two meals; the butter is not affected; the cows are pastured and eat no other food; and it has been ascertained, that the evil is not confined to the produce of any one cow in particular, of the five milked in the dairy alluded to especially; and the milk is immediately poured from the pail into white Staffordshire milk-pans.—*Lactens.*

Early Harvesting.—Having cut a field of Wheat about ten days before being perfectly ripe, according to the views recorded in some of your late publications, I am desirous of acquainting you of the difficulty I had in making sale of it, although it was on all hands acknowledged to be a good grain of steel Wheat. When I sent it to the mills it was rejected, as having been cut green. My horses returned with their loads, and I was forced to send the grain to Limerick market, a distance of 28 Irish miles, where I with difficulty got only 15*d.* per stone. Now, Sir, if it be true that the farmers and millers of England find it advantageous to cut green, how came such ignorance on the part of those in a quarter of the country where so much Wheat is grown, and where there are so many extensive buyers? I lost the expense of my horses and men for one day, and the carriage of 8*d.* per cwt. to Limerick. Any information you can give me on this head will be thankfully received; and should you be able by advice or reproval to effect a change in the views of the millers, next year may not be so unfortunate to those who cut green.—*J. V. Bruden, M.D.*

Thin Sowing.—Having read Mr. Davis's little "Treatise on Thin Sowing," I was induced last spring to try it on a small scale with Scotch Potato Oats without dressing. The following is the result:—On two lands, containing 1 rood 6 perches, seed at the rate of 2 bushels per acre, drilled 12 inches between the rows, produced 2 qrs. 3½ bush.; weight of Oats, 41 lbs. per bushel; straw, 23 trusses, 4 lbs. The adjoining two lands, with the remainder of the field, sown at the rate of 3 bushels per acre, 9 inches between the rows, produced 2 qrs. 1 bush. 1 pint; weight 41½ lbs. per bushel, and 20 trusses 2 lbs. straw; which shows an advantage of the thin sowing at the rate of 1 qr. 1 bush. of Oats, and 10 trusses 22 lbs. straw per acre, besides the difference of seed. The thin sown Oats were not so ripe when cut as the others, which I think will account for their being rather lighter. The increase of Oats, straw, and saving of seed, will amount to about 1*l.* 15*s.* per acre.—*Sam. Relf, Reigate.*

Curiosity.—I send you a Potato into which a young shoot of a reed has grown so as to split the Potato. This occurred in some boggy land which has been made dry; the reeds are not quite killed yet, because the subsoil is blue clay. I suppose that the reed has been driving into the Potato for moisture, being at the last gasp from extreme thirst. Are such instances common?—*J. S.* [We have known the roots of Couch-grass pierce the bulb of the Wild Hyacinth.]

Weeds.—A correspondent of yours wrote some time ago upon the destructiveness of Weeds on the headlands of fields and under hedges; pray let me add railroad-banks and waste land. Surely it would pay for the poor to be employed cutting down Thistles and other Weeds, which are now on all the roadsides, and are elsewhere allowed to flower and seed, and to be spread all over the adjoining country, increasing the trouble of the poor farmers a thousand fold for the year following.—*Cockney.*

Dipping Sheep.—I believe I once before alluded to this in your Paper. I, however, do it again in consequence of having just had my flock dipped for this year (now the 4th or 5th year I have had it done), and in 51 long-wooled sheep there was not (as my man assured me) one single tick to be seen. If those who keep sheep would reflect upon the comfort to the animals, of being divested of the swarms of vermin which generally crowd them, humanity alone would surely lead them to undergo the trifling expense and trouble. But when you add to this the great difference in the quantity of food consumed—between a sheep that, as soon as it has satisfied its appetite, adjourns to the nearest gate or post, and there rubs might and main till his empty stomach drives him to his pasture, and another sheep, who, having filled itself quietly, lies down and takes its nap—it becomes a question, and, with large flock-masters, a serious question of profit and loss. And the only thing, but at the end of a few weeks the undipped sheep will, as well as having destroyed much food, be infinitely in worse condition than the dipped one. When I first heard of Bligh's Composition, I had a valuable hook devoured by scab, which I could not cure, though I tried all means, and went to much expense. One dipping cured

them at once. My sheep are now all I could wish; they are always easy, never rub, lose no wool, and attend at all times to their business—eating and sleeping. I have induced many of my neighbours, during the last few years, to try the composition, lending them my apparatus, and all I can say is, that all who used it last year have borrowed it this; all say it cured the scab, and one that it also destroyed the foot disease, which has been so prevalent. This last, however, I do not vouch for, but for the immense comfort to the sheep, and benefit to the owner of the flock in the other respects, I have great pleasure in giving my humble testimony; and, as a lover of sheep, from a wish that so very valuable, simple, and inexpensive a process should be resorted to by all who keep them, and from a conviction that great benefit would arise to the farmers and the community at large, for the increase and value of mutton and wool, I should be very glad if you could find room for this communication. I would gladly afford information to any one on the subject, but they would get it better, perhaps, from the seller of the composition, Mr. Bigg, with whom I beg to say I have no communication but as a purchaser. —*W. D. F.* [A known correspondent.]

Potatoes.—Several of your correspondents appear to have sought in vain for a remedy for the grub and wireworm; my plan is this, and I think it the best remedy where there are no rooks in the neighbourhood:—On taking up Potatoes, I coax two or three favourite old hens beside me, and when I turn up an infected Potato I disperse the earth about, although in most cases shaking the stem is sufficient, and should they stray I reserve them in a basket for them. If farmers would but take a little trouble in light soils, they would discover hundreds of new sorts of Potatoes among their old stock, without being obliged to change their seed and waste their time in descanting upon their seed being degenerate and infected.—*Verax.*

Roots of Wheat.—In your Number of the 31st of August last, you express a wish to be informed as to the extent of the roots of the Wheat plant. About 30 years ago, a series of experiments were made by Mr. Badcock, of Pyston, near Watlington, in Oxfordshire, with a view to ascertain this fact. I am told that by digging pits by the side of the plants, he extracted the roots entire. He embodied the result of his experiments in the form of a letter to the late Earl of Macclesfield, then President of the Board of Agriculture in London: This letter was published by the Board, and a medal awarded to the writer. The late Sir Jos. Banks, to whom the subject was new, provided glass cases for the specimens, which were kept at the office of the Board, and on its being broken up, it is believed that the specimens were removed to the Society of Arts. In addition to this, a plate was engraved from drawings made by Mr. Badcock's son, now resident in Oxford, by which it is shown that the roots descended into the earth six feet. There are six figures in the plate, drawn to scale, showing that at progressive stages of the growth of the plant, the root descends rather deeper into the earth than the plant rises above it. This plate may be found in a book published by Mr. Badcock on the comparative price of Wheat and other grain for a long series of years.—*J. C. C.*

FARMERS' CLUBS.

Leyland, Lancashire.—At the Annual Meeting and Show of the Agricultural Association here, a Report on the farms competing for prizes was made by Messrs. Logan and Lauder, the inspectors, from which we make the following extracts:—The inspectors urge on those who have the management of the different farms that have been inspected, with reference to the thorough drainage of the land, that drains be cut in a parallel direction, so as to carry off the water that falls on the surface, and also the under water, in the shortest and straightest course that can be found, and also that they be cut to the depth of from 28 to 30 inches, instead of from 18 to 20 inches, which would be more permanent, and the stones would be out of the reach of the plough. The inspectors draw attention to the want of green crops, such as Turnips and Beans, in proportion to the size of the farm; those crops should be sown in drills, instead of the broadcast system. The inspectors advocate the above principles, and they practically put them in execution upon land inferior to any of the farms which they have inspected; and they consider that the system can with profit be generally adopted. Nothing, they presume, is so likely to effect good cultivation, as having the land dry, keeping it perfectly clean, and under the green-crop system, with a proper rotation of white crops. And they wish to draw the attention of the farmer to the great essentials of Turnip growing, viz., a soil thoroughly dry, and well cleansed and pulverised when the seed is sown, care in keeping it clean, and attention to the thinning of the plants, at once, and at proper time, and at proper distances from each other; care in removing the soil from the roots of the young plants, and in the earthing up at the latter end of the season, not to lay the soil to the Turnip, but to allow the plant to have room to grow on the top of the drill, as the inspectors have found several crops heaped up in the same way as Potatoes, which is against the swelling of the root. The inspectors recommend a more extensive breadth to be cultivated, as they have found, generally, a short breadth to the size of the farm. Many allege, and no doubt with truth, that additional labour and additional manure are wanting in the cultivation of green crops, Turnips especially; but the inspectors submit that, unless labour and manure be expended, there cannot be any remunerating return to the farmer. The abundant supply of food for cattle by the green crops, particularly in a season such as this, when short of hay, will amply compensate for any additional outlay. The farmer who has cultivated his green crop can always see his cattle looking well, and is at the same time continually laying up a plentiful supply of rich manure for his future use. The inspectors have also to state that Mr. Scotson's Turnips are the largest in growth that have come under their notice this season; but are sorry to observe many entirely eaten off for the surface of the land by rabbits or hares, which is very discouraging to the tenant, after all the expense and trouble of cultivation. The entries for the cultivation of drilled Beans have been few, but the inspectors would suggest a more extensive cultivation of these crops over those broadcast. The land, in the first place, must be clean. Wheat or Oat stubble early ploughed in the autumn, dry; and in the spring, to forward the sowing in due season, the grubber is the only implement that should be used before drilling up; a fair supply of manure should be used, and the after-culture properly attended to with the hand-hoe and drill-harrow. For draining, the entries have been few, and it appears to have been very much neglected over the Society's district. To this subject the inspectors wish to call the attention of the proprietors, as this permanent improvement is the foundation of all good husbandry. Unless the land be laid thoroughly dry it is useless for any one to attempt to improve it with profit. The inspectors would call the attention of the Society, and proprietors in the district generally, to the drainage on the farm of Mr. Hood, New Inn Farm,—he having drained 5209 rods, of five and a half yards per rod, this spring and summer, the work being in operation when they were on the inspection, on the 3d of September last. The drains run parallel to each other, and at regular distances, from 5 to 6 yards apart, and carried through the whole field, without reference to the wet or dry appearance of the land: the small drains are cut 30 inches deep, filled 15 inches with clean gravel, and covered with a sod, and the soil filled in. The main drains are cut 32 inches deep, and built with stone, and filled with gravel above the covers. The landlord opens and fills the drains, and the tenant carts the material. The work is well executed in all the departments, and gives great credit to the landlord, agent, and workmen. (Signed) JOHN LOGAN, GEORGE LAUDER. — The following remarks were shortly afterwards made by Mr. Neilson: He said he had himself begun to drain, and drained 45 acres with broken stone, and Lord Derby, his landlord, had afterwards drained 50. Now, the entire charge of draining was paid by Lord Derby, and interest charged. Drainage is the province of the landlord. It is a permanent improvement, and should be effected at the cost of the owner. It was better that the landlord should do this and charge an additional rent, than that the tenant should so invest his capital, which might be otherwise employed in making improvements more within his province. It was the tenant's interest to pay a higher rent for a drained farm than an undrained one. When he proposed to pay 10 per cent. on the outlay, his landlord had said that it would be a high charge, as they were draining extensively. He said he would rather pay 20 per cent. than it should be undone. It was better for the tenant to pay 3*l.* per acre for drained land than 2*l.* per acre for land undrained. If the landlord was unable or unwilling to pay the expense, let the tenant get a long lease and undertake it himself. Draining was the first step; it must be taken. He had said what was the landlord's work; now he would tell them what was the tenant's. Deep ploughing, manuring, and weeding clean. How often did they hear tenants complain of the expensiveness of manures, at the same time that they were allowing the most valuable portion—liquid manure—to run waste into the nearest ditch! How could they expect to farm successfully thus? A hole made in the ground, or a tub sunk, would collect the liquid manure of two or three pigs and two or three cows, and the wash of the house, and this would suffice for 30 tons of Turnips and 70 bushels of Wheat. The tenant farmer is the centre of the social system of Agriculture; he supports, on the one hand, landlords by rents, and on the other, labourers by wages.

Harleston, Norfolk.—I herewith furnish you the resolution arrived at by the members of the Harleston Club, on the 2d inst., on the subject of Farm-labour:—"That it is the opinion of this Meeting that 30*s.* per acre is the amount generally expended in labour on the well-cultivated heavy land farms in this district, although the average is considerably less; but that, if security be given to the tenant, on the principle advocated by this Club, viz., length of tenure or Corn-rents with liberal covenants, a sum varying from 30*s.* to 40*s.* per acre, according to soil and situation, might be advantageously expended." It cannot but be exceedingly regretted that the landlord and tenant's views should be so disunited; and until a great change is effected, agriculture will slowly progress.—*J. G.*

Reviews.

The Book of the Farm. By Henry Stephens, Editor of the "Quarterly Journal of Agriculture." William Blackwood and Sons, Edinburgh and London.

THE last part of this voluminous work is now published. The unnecessary prolixity with which its author is often justly chargeable, is certainly too small a fault in any degree to balance the many and high merits which belong to it. In the last part there are useful chapters on Agricultural Experiments, on Farm Accounts, and on the Rent, Lease, Stock and Capital of a Farm.

The Author concludes his work with the following passage, addressed to his readers, descriptive of good farming:—

"If you will but follow the prescriptions I have given, for conducting the larger operations of the field, and for treating the various animals of the farm; and—not to mention the proper ploughing and manuring of the soil—as the practice of every farmer demonstrates the necessity of affording due attention to those most important, because fundamental operations;—if you finish off your fields in a manner indicating care and neatness, ploughing round their margins, and turning over the corners—if you keep your fences clean and in a state of repair—your fields free of weeds—if you give your stock abundance of fresh food at regular intervals in winter, and supply them with plenty of clean water on fresh pastures in summer—if you have the farm-roads always in a serviceable state, and everything about the steading neat and orderly;—if you exhibit skill and taste in all these matters, and put what is called *a fine skin* on your farm, you will not fail to earn for yourself the appellation of a good and exemplary farmer."

We may safely assert that the "Book of the Farm" is the completest work on Agriculture which has yet appeared in this or indeed in any other language.

The Farmers' Ready Reckoner, or Glasnevin Agricultural Tables, by Thomas Skilling, Agriculturist to the Board of Education, National Model Farm, Dublin. Curry and Co., Dublin.

A LITTLE volume filled with Tables, illustrated by examples, for showing by inspection the agreable quantity of any growing green or grain crop, in drill or broadcast, and also for regulating the correct distribution of farm-yard and other manures. It also contains a Table giving the quantity of labour of various kinds that ought to be performed in a given time at a given rate of working. It gives the results in measures of various kinds; according, for instance, to the imperial, Irish, or Cunninghame acre. The greater part of the book is taken up with Tables for enabling the calculation of such problems as the following:—

"Having a field sowed one-half with Rape and the other half with Vetches for spring food; and being anxious to know the comparative value of these crops for the purpose, it is desired to know how this may be accomplished. Having taken a square yard, that is, 36 by 36 inches, in different parts of each crop, and obtained an average, I find the Rape weighs 7 lbs. and the Vetches 5½ lbs. I go to Table No. 10, 36 by 36 inches, and opposite

	Tons.	cwt.	qrs.	lbs.	
7 lbs. in left hand column I get	15	2	2	0	for Rape.
5½ " " "	11	17	2	20	for Vetches.
In favour of Rape	3	4	3	8	"

Miscellaneous.

Agricultural Implement Clubs.—You expressed a desire to hear from some member of the Richmondshire Agricultural Association, how the plan adopted by that Society of purchasing improved agricultural implements, using them through the year, and then selling them, had answered. When this Society about three years ago began to attract attention, a resolution was carried at the general meeting, by which the President, R. M. Jaques, Esq., was empowered to purchase for the Society agricultural implements to the value of 100 guineas. Among the implements selected were Crosskill's Clod-crusher, Grant's Hay-rake, the Uley Cultivator, Ducie's Chaff-cutter, Wedlake's Cake-crusher, Biddel's Scarifier, Cottam and Hallam's Dynamometer, &c.; most of which were previously unknown to the majority of the farmers in the district. Some of these articles were taken out and tried by various members of the Society during the following year; but we find it stated in the Transactions of the Society for 1843, that, "In the Report last year it was proposed: first, that the implements purchased by the Society should be tried during the present year, by any members wishing to do so; this, however, has been found almost impracticable to any extent, from their being constantly out of order; and, secondly, it was proposed that they should be sold by auction at the ensuing meeting. Your Committee have, however, thought it a more desirable plan, especially as securing the funds of the Society, to award them as premiums, which will enable them to purchase again during the present year." Several of these useful articles were consequently disposed of in this way to parties who were likely to appreciate their worth; and the Society again resolved "that the President should be empowered to spend, during the ensuing year, for agricultural implements, a sum of money not exceeding 100 guineas." In accordance with this resolution, additional articles of great utility were carefully selected from the works of Ransome, Ducie, Dean, Crosskill, Barrett Exall and Co., and other first-rate makers. This encouragement to the implement manufacturers, joined to an avowed intention of giving a full and fair trial to each article exhibited, induced many of the most eminent manufacturers in the kingdom to attend the Richmondshire Agricultural Society's meeting in 1843. A whole week was spent in examining and carefully trying the various implements brought forward, and knowledge of lasting importance to the farmer was disseminated. The members of this Society, and the agriculturists of the district generally, have thus had an opportunity of seeing implements of high pretensions and great cost put to their various uses, and their merits fairly tested, without any risk to themselves. The result has been shown by many of our best agriculturists getting chaff-cutters, drags, clod-crushers, &c. &c., for their own farms; and by our local implement makers showing a desire to produce useful articles of superior work-

manship. It seems likely, however, that the Society will at present cease purchasing implements in this manner. The principal object has been achieved, namely, that of rousing a spirit of inquiry in the breast of the farmer, and showing him that better implements for farm purposes than those he had been accustomed to had been invented; implements calculated to lessen the expense of producing his various crops, and thus enabling him to meet with greater ability the many claims upon the fruits of his hard-won industry.—*Correspondent of Mark-lane Express.*

Report of the Thorough-Draining executed on the Estate of Edward Lucas, Esq., Castle Shane, Monaghan, by Fitzherbert Filgate, Esq.—We next proceed to the field containing 7A. 0R. 22P. This field is likewise stiff clay, upon a subsoil much resembling that already described. The draining of this and the adjoining field was extremely simple, from the slope of the ground being uniform and all in one direction. The prices paid in this case were as follows:—for breaking stones, sodding, and filling 3½*d.* per perch for small, and 5*d.* per perch for main drains; the stones in this case were carted a mile, and provided by the contractor. The cost was as follows:—

No. of acres in field.	No. of perches of small drains	Price per perch.	No. of perches of main drains.	Price per perch.	Total cost of field.	Cost per acre.
A. R. P.		s. d.		s. d.	£ s. d.	£ s. d.
7 0 22	1131¼	0 5½	{ 57 3 5th. / 24	1 0 / 0 5½	29 4 7	4 1 11

There are 24 perches of main drains charged at 5*d.*; that is the cost of cutting, as we had stones that had been in old houses, and drew them with the farm-horses. If the same price be charged for these 24 perches as for the rest, 15*s.* must be added to the cost, making it amount to 29*l.* 19*s.* 7*d.* This field was broken up for Oats, and produced a very fair crop, not yet threshed. The next field, which is only separated from the preceding by a fence, was then commenced. It nearly resembles that last described, as to inclination of surface. The soil is heavier, being for the most part stiff yellow clay; a part of this field was first done, but the person who had contracted to lay down the stones, not being able to fulfil his contract within the time specified, and seed-time being at hand, I was obliged to defer doing anything more until after harvest, which, however, gave me an opportunity of testing the difference in produce of the drained, compared with the undrained land, and the result is the more satisfactory, as the ground was not selected to make the experiment on. The part of this field first done consisted of 4 A. 2 R. 1 P., and was paid for at the following rates:—

SMALL DRAINS.

Cutting drains, breaking stones, filling, and sodding	3½*d.* per perch.
Laying down stones	2 3-16ths ,,
	5 5-16ths

MAIN DRAINS:—

Cutting, &c.	5*d.* per perch.
Laying down stones	6 7-8ths ,,
	11 7-8ths

The total cost of this part of the field would therefore be as follows, viz.:—

Number of Acres in field.	No. of Perches of small Drains.	Price per Perch.	No. of Perches main Drains.	Price per Perch	Total cost of field.	Cost per Acre.
A. R. P.	{ 728 / 76 4-5ths	s. d. / 0 3 5-16th. / 0 2 5-16ths.	} 49½	s. d. / 0 11½	£ s. d. / 10 11 4	£ s. d. / 1 6 9
4 2 1						

There were 76 4-5ths perches to which stones were drawn by the farm-horses, the stones having been thrown in a heap at a former period. The main drain was carried farther than the parallel drains extended, leaving 11 1-5th perches to be made. The remainder of this field, containing 4 acres 1 rood, was proceeded with immediately after harvest. The prices for cutting drains, breaking stones, sodding, and filling them, were the same as that before given in same field—namely, 3½*d.* per perch. The stones were bought at 3*d.* per ton, and the drawing was paid for at the rate of 3*s.* per day for cart, man, and horse. The expense of the stones was in this way very considerable; I conceive too high, but circumstances occasioned the trial. The former prices, in consequence of the great competition, were certainly too low; the expense in the present case was nearly 5½*d.* per perch. The outlay of this part of the field stands as follows:—

No. of acres in field.	No. of perches of small drains	Price per perch.	No. of perches of main drains.	Price per perch.	Total cost of field.	Cost per acre.
A. R. P.		s. d.		s. d.	£ s. d.	£ s. d.
4 1 0	645 1-5th.	0 6½	11 1-5th.	0 9	22 16 0	5 7 9

The produce of the different parts of the field was kept separate, and was found to have been as follows:—Part drained, containing 4A. 2R. 1P., produced 583 stones of Oats, being 118 stones per acre, while that part undrained, containing 4 A. 1 R., produced only 336½ stones, or at the rate of 79 stones per acre. The difference in value of crops, taking Oats at 6*d.* per stone, would amount to 26*s.* per acre, exclusive of the value arising from increased quantity of straw, which was at least one-third more on the part drained.

We next proceed to the field containing 6 A. 0 R. 17 P. The cutting the small drains, breaking stones, sodding, and filling, was done for 3½*d.* as before. The stones were quarried in a field in the demesne, at 1 1/16*d.* per perch, for large and small drains. The carting was done with the farm horses, the stones having been laid down as occasion offered. In this way the money actually paid amounted to—

No. of acres in field.	No. of perches of small drains.	Price per perch.	No. of perches of main drains.	Price per perch.	Total cost of field.	Cost per acre.
A. R. P.		s. d.		s. d.	£ s. d.	£ s. d.
5 0 17	774 3-5ths.	0 4 17-32	280	0 6 16-32	22 1 11	3 12 4

We next proceed to the field containing 1 rood, 5 acres, 20 poles. The soil of this field and the one next to it is greatly inferior to any of those hitherto described, as it chiefly consists of thin clays upon a subsoil of impenetrable hardness, abounding in many parts of the field, with moorband pan. It was drained last autumn, and it is intended to have it ploughed for Oats this season, and after that crop is removed, then subsoil-ploughed. The prices as before, cutting sodding, breaking stones, 3½*d.* per perch for small, and 5*d.* per perch for main drains. The stones were quarried in a field in the demesne, and carted by the farm horses; the quarrying was done for 1 1/16*d.* per perch, and the main drains were filled with stones that had been previously gathered on the surface. As in a former case, the account given is that of the money actually expended, which, therefore, makes no charge for the cartage. The price named for cutting the main drains, 5*d.* per perch, is more than that usually given, when they are filled with broken stones; but as it was necessary to cut a part of it through a knoll, to a very considerable depth, an extra price was allowed.

No. of acres in field.	No. of perches of small drains.	Price per perch.	No. of perches of main drains.	Price per perch	Total cost of field.	Cost per acre.
A. R. P.		s. d.		s. d.	£ s. d.	£ s. d.

—*From the Irish Agricultural Society's Report.* [*To be continued.*]

Notices to Correspondents.

BURNET.—*Elyste.*—It is not a sufficiently large or luxuriant plant to supersede Lucerne, Sainfoin, or Clovers. It is a hardy plant, and keeps green all the winter. It is not particularly relished by cattle.

"CRITTAM," or "CRIDHAM" WHEAT.—*Kirklinton.*—Can any one give us the history of this variety?

DISEASES OF WHEAT.—*Brenchley.*—Your curious specimen will, if possible, be noticed next week. You have got rain enough now, have you not?

DRAINAGE.—*E. B.*—We do not know of any test of tenacity or wetness of soil. 16 to 20 feet is ordinarily an efficient interval between drains. See where land of similar quality to your own has been successfully drained, and imitate the plan there adopted, in its essential features.

GRASSES.—*Eskdale.*—No. 1, Festuca pratense, Meadow Fescue; No. 2, Cynosurus cristatus, Crested Dog's-tail Grass; No. 3, not known, specimen imperfect; No. 4, a Festuca. Your ram should be fed on nourishing food of any kind. Are your Swedes ready yet? Give him some of them, and 12 to 16 ounces of oil-cake daily. We do not know the composition of the material sold by Biggs for dipping sheep.

GRASS-LAND.—*A Subscriber.*—Your proposed application of gypsum and farm-yard manure is good.

MODE OF CROPPING.—*C. J.*—Grow 1 acre of Lucerne, and of the other 12: you can have 4 acres of Carrots, 2 of Parsnips, 3 of Mangold Wurzel, 2 of Clover, and 4 of Wheat, of which 2 should be sown with Clover-seeds. The green crops will give you sufficient food, and the grain crop sufficient litter for your stock. You had better plough now in ridges, and sow 4 acres with spring Wheat, with 2 of which sow Clover, and, manuring sufficiently, you can cultivate the necessary green crops in spring.

NOTICES TO CORRESPONDENTS.—*J. Clark.*—We shall in part adopt your suggestion, and when the answer asked for is of general interest, state the question as well as answer.

SHEEP FEEDING.—*A Subscriber.*—The practice of house feeding is extending, and we should be glad if our subscribers could give us their experience of it; we know of no work exclusively on this subject.

SHEEP-SALVE.—*A Subscriber.*—We know of no other evidence on the subject than that in the Highland Society's Transactions, which you appear to have seen. It appears to us sufficiently satisfactory.

TRANS. OF SOC. FOR ENCOURAGING ARTS, &c.—*J. S.*—We should be much obliged by extracts.

VALUE OF FOOD.—*Melibœus.*—You may safely consider the prices respectively of Foreign and British oilcake as accurately representative of their relative values as food. The experiments of foreign agriculturists indicate 100 lbs. of hay as being equal in value to 60 of oilcake. This appears to us incorrect; 1 lb. of oilcake is equal to two or three of hay.

*** As usual, many communications have been received too late.

Markets.

SMITHFIELD, MONDAY, Oct. 14.—Per stone of 8 lbs.

Best Scots, Herefords, &c.	3s 10	to	4s 0	Best Downs & Half-breds	3s 8	to	4s 0
Best Short Horns	3 8		3 10	Best Long-wools	3 6		3 10
Second quality Beasts	3 8		3 8	Ewes and second quality	3 0		3 6
Calves	3 0		4 0	Pigs	3 4		4 0

Beasts, 2060; Sheep, 21,600; Calves, 118; Pigs, 270.

Our supply of Beasts is smaller, yet it is quite adequate to the demand; the best qualities, however, more readily realise our top quotations; the second class Beasts still form a large portion of the quantity in market, and meet with a very dull sale at about late rates. Sheep are less in number to-day; still, trade is heavy, owing to a general depression, although somewhat brisker than last week; we cannot notice any quotable advance, only that prices are more firmly supported, and in some few instances the best qualities make a trifle more money. Veal trade is exceedingly heavy, except for the very best Calves, which are not very plentiful; the middling qualities make very low prices. Pork trade is steady.

FRIDAY, Oct. 18.

We have a large supply of Beasts, amongst which we notice several from Holland, in very good condition, and which meet a ready sale; good Beef being still a scarce article, prices remain about the same as on Monday for the best qualities; the middling, of which there is a large proportion, cannot be all sold. The supply of Sheep is small; we have a brisker trade, the best Downs, &c. making a little more than 4s, and Long-wools 4s 10d per 8 lbs. Veal trade continues very heavy; the best Calves make about 4s, but there is a large quantity of second rate from 3s to 3s 6d per 8 lbs. Pork trade is rather brisker, at from 3s 4d to 4s 4d.

Beasts, 321; Sheep, 480; Calves, 248; Pigs, 220.

E. West Smithfield.

POTATOES.—SOUTHWARK WATERSIDE, Oct. 14.

The arrivals during the past week have been limited—yet there are some arrivals from most of the usual districts that supply this Market, but owing to the mildness of the weather, the demand is small, and our trade extremely dull at the following prices. One small cargo of Paynton Potatoes are selling at 90s. Rhone, 40s; Whites, 40s.

York Reds	80s	to	90s
Perth	80		—
Yorkshire	—		—
Early Devons	—		—
Late Devons	—		—
Cornwall	80		—
Jersey Blues	80		—
— Whites	40		50
Kent and Essex Whites	80s	to	—

Wisbeach Kidneys	—		—
— Whites	80		85
Gourlays Blues	80		—
— Whites	40		50
Prince Regents	—		—

R. HARRIS.

COVENT GARDEN, OCTOBER 18.—The supply of fruits and vegetables during the week has been tolerably good, but trade has been somewhat dull. Pine-apples are rather scarcer than they were last week; they are also slightly advanced in price. Hothouse-grapes remain nearly the same as mentioned in our last Report. A few Spanish Melons are in the Market, and some of English growth are also to be met with; but they are getting very scarce. Of good dessert Pears there are plenty, and Apples are also pretty abundant. Impératrice and Golden Drop Plums are to get to be seen; but they are becoming scarce. Damsons are also scarce. Walnuts are plentiful, and a few Chesnuts are also supplied. Bitter Oranges are yet in the Market. Some good Specimens of Cucumbers are offered at about the same prices as quoted last week. Vegetables are, generally speaking, good in quality. There is an abundant supply of all kinds of Greens. A few French Beans may be met with, but they are getting very scarce. Turnips and Carrots are excellent in quality, as is also Celery; the red sort is a little dearer. Endive and Lettuces are well supplied. Jerusalem Artichokes are becoming more plentiful. Vegetable Marrow and Tomatoes have suffered from the cold nights, and are consequently scarce. Cut flowers chiefly consist of Sedum Sieboldi, Combretum purpureum, Camellias, Roses, Fuchsias, Pelargoniums, Neapolitan Violets, Picotees, and Heaths.

FRUITS.

Pine Apple, per lb., 2s to 6s	Filberts, per 100 lbs., 35s to 36s
Grapes, Hothouse, p. lb., 1s to 3s	Chesnuts, per peck, 2s to 3s

JAMES PEARCE, Wool Broker.

MARK-LANE, MONDAY, Oct. 14.

THERE was a fair supply of Wheat this morning from the home counties, a large proportion of which was of inferior quality; the trade opened heavily, and must be written 1*s.* per qr. lower for all descriptions, some quantity remaining unsold at the close. The transactions in Free Foreign were exceedingly limited, Millers evincing great unwillingness to comply with the present rates, which are firmly insisted upon. There is some demand for Bonded, for export to Holland and Belgium.—The finest samples of Malting Barley command an advance of 1*s.* per qr.; inferior and grinding are unaltered in value.—Peas of all sorts are 1*s.* dearer.—Beans rather a better sale.—The Oat-trade is firm at last week's prices.

FRIDAY, Oct. 18.

The arrivals of all descriptions of Corn since Monday have been small. The Wheat-trade continues dull, but prices are unaltered.—Canadian and American Flour meets a ready sale at our quotations.—26,853 qrs. Barley paid duty in this Port on Wednesday; this morning it met an improved inquiry, and a slight advance in the value is general, amounting on fine Malting qualities to 1*s.* per qr.—Beans and Peas are in good demand, and the turn dearer.—Oats are held for more money, but sales are difficult at an advance.

BROMPTON-PARK NURSERY AND SEED ESTABLISHMENT.—Established 1681.

MESSRS. GRAY, ADAMS, AND HOGG have much pleasure in directing the attention of their numerous customers to their extensive NURSERY STOCK, consisting of Dwarf and Standard Maiden and Trained Fruit-trees, Figs, Vines, &c. &c., all of which are this season of a very superior description, and will fully maintain the reputation this establishment has for such a long period of years enjoyed for producing these articles. The peculiar nature of the soil renders the removal of all ornamental trees and shrubs almost certain, of which there is a select and extensive collection; together with everything that is desirable in the class of Greenhouse and Herbaceous Plants.

MARKET GARDENERS are invited to inspect a fine stock of Half Standard Apples, Pears, and Plums, which they will find well worthy their attention.

The SEEDS of this season that have come to hand are generally of a very fine quality, and of which Catalogues will be issued in due course.—Kensington-road, October, 1844.

TENTH ANNUAL SALE OF DUTCH ROOTS.

MR. JAMES IZOD begs most respectfully to announce, that he will SELL BY AUCTION, at the Auction Mart, on TUESDAY NEXT, October 22, at Twelve for One, one CASE of very fine assorted DUTCH BULBS, comprising very fine named double and single Hyacinths, Narcissuses, Gladioluses, Ranunculuses, Anemones, Crocuses, Crown Imperials, Lilies, very fine Duc Van Tholl and other Tulips, Snowdrops, and other choice roots.

May be viewed the morning of sale, and Catalogues had at the Auction Mart, and of Mr. Izod, 2, Warnford-court, Throgmorton-street, City.

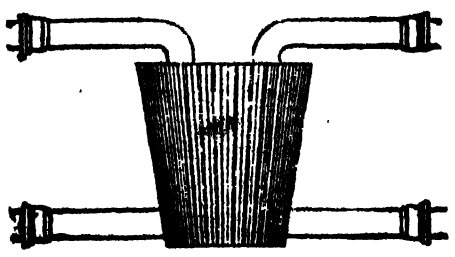
TO TULIP-GROWERS.

TO BE DISPOSED OF, 31 Rows, 7 in each, of fine TULIPS, the property of a gentleman deceased. They cost originally 12*l.* Selections of rows, or separate bulbs, may be had at half-price, or the whole Collection for 40*l.*—Apply for Catalogues, by letter, to A. B., Mr. Button's Library, Clapham Common, where further particulars also may be learned personally.

CONICAL BOILERS.—The Boilers invented by John Rogers, Esq., are made of several sizes, and may be obtained of John Sherwin, Ironmonger, Sevenoaks, Kent.

They may be seen in operation at Messrs. Chandler's, Vauxhall; Loddiges', Hackney; Henderson's, Pine-apple-place, Edgware-road; Rollisson's, Tooting; Pontey's, Plymouth; The Horticultural Society's Gardens, Chiswick; and in the Gardens of the Royal Botanical Society, Regent's-park.

HOT-WATER APPARATUS FOR HEATING HORTICULTURAL BUILDINGS, DWELLING-HOUSES, CHURCHES, and MANUFACTORIES, upon improved principles, and at very moderate charges, erected by DANIEL and EDWARD BAILEY, 272, HOLBORN.



D. and E. Bailey having devoted much time to the consideration of this subject, and had much experience in the erection of apparatus for the above-mentioned purposes, have, by improvements suggested in their practice, rendered their mode of heating not only very efficient, but very simple, and have combined durability in the apparatus with economy in the charge. They have erected apparatus in England, Scotland, and Ireland, for many noblemen and gentlemen, and have had the honour to be employed by the Horticultural Society of London, in executing the works of their splendid Conservatory, lately erected at Chiswick.

D. and E. Bailey also construct in metal all descriptions of Horticultural Buildings and Sashes, and invite noblemen, gentlemen, and the public to an inspection of their various drawings and models, at 272, Holborn, where they have the opportunity of exhibiting, amongst other metal works, an extremely complete and convenient kitchen apparatus, or range, adapted for the continued supply of hot water, and an arrangement of the oven more complete than has hitherto been brought before the public.

D. and E. Bailey were the first to introduce metallic curvilinear houses to horticulturists, and can refer to the Conservatory attached to the Pantheon as one of their works, besides many others in this country and on the Continent.

D. and E. Bailey have prepared a quantity of the Galvanic Plant Protectors, which are now ready for immediate delivery; they beg to introduce to public notice a new Trough Pipe, for Orchidaceous or other Houses where vapour is constantly, or at intervals required, and which may be seen at their Manufactory.

BURBIDGE AND HEALY'S NEW BOILER and FURNACE for HORTICULTURAL PURPOSES.
Registered under 6 & 7 Vict., Cap. 65.
No. 130, FLEET STREET, LONDON.

Burbidge and Healy respectfully inform the Horticultural Public that they have constantly on hand an extensive assortment of their new Boiler and Furnace Doors. In very numerous cases where they have been fixed, they have the highest testimonials of their complete success: for the further assurance of those who may require this apparatus, Burbidge and Healy refer them to the Horticultural Society's Gardens, Chiswick; also to Mr. Gandellini, Garden Architect, &c. &c., Chiswick Nursery, in the same neighbourhood, where the apparatus may be seen in successful operation, in connection with their new Tanks. The following are the present prices:—

Plain Boiler.	Patent Door and Frames.	Fire-bars & Dead Plate.	Flue Door.	Damper.	Will heat of Pipe.	Forcing Pit, Length by feet.
in.	*l.* *s.*	*s.*	*s.* *d.*	*s.* *d.*	*s.* *d.*	
10	1 5	20	7 6	6 6	6	30 feet.	12 to 20
Ribbed Boiler.							
10	2 2	20	10 6	7 6	6	50 to 70 ft. 4 in.	Under 25 to 40
12	2 15	25	12 6	7 6	6	60 to 125 feet.	40 to 65
14	3 10	25	17 5	8 6	6	150 to 250 feet.	65 to 100
18	5 5	35	25 0	8 6	6	300 to 400 feet.	Warm a grapery 25ft. long, hade pit 35ft.
24	8 15	50	35 0	8 6	6	600 to 900 feet.	

If 8-inch pipe be used, one-third more. If 6-inch pipe, as much more.

The above quantities are rough estimates, which may be varied by enlarging or contracting the fire, or by regulating the flue door. It is possible to heat a much larger quantity of pipe with the boiler; but it would be done at great loss of fuel. The above proportions can be generally relied on as a near approximation to what is correct.

STEPHENSON AND CO., 61, Grasechurch-street, London, and 17, New Park-street, Southwark, Inventors and Manufacturers of the Improved CONICAL and DOUBLE CYLINDRICAL BOILERS, respectfully solicit the attention of scientific Horticulturists to their much approved method of applying the Tank system to Pineries, Propagating Houses, &c. by which atmospheric heat as well as bottom-heat is secured to any required degree without the aid of pipes or flues. S. & C. have also to state that at the request of numerous friends they are now making their Boilers of Iron as well as Copper, by which the cost [illegible]ers, which are now so well known, scarcely [illegible], but to those who have not seen them in operation [illegible]ses will be forwarded as well as reference of the [illegible] authority; or they may be seen at most of the Nobility's seats and principal Nurseries throughout the kingdom.

S. & Co. beg to inform the Trade that at their Manufactory in New Park-st., every article required for the construction of Horticultural buildings, as well as for heating them, may be obtained upon the most advantageous terms.

Conservatories, &c. of Iron or Wood, erected upon the most ornamental designs. Balconies, Palisading, Field, and Garden Fences, Wire Work, &c. &c.

COTTAM AND HALLEN, Engineers, Iron-founders, &c., &c., No. 2, Winsley-street, Oxford-street, London, and at Cornwall Road, Lambeth.

HOTHOUSES, CONSERVATORIES, &c., made upon the most improved principle, either of iron or of iron and wood combined, which can be fixed complete in any part of the Kingdom, at very low prices.

HOT-WATER APPARATUS for heating Hothouses, Conservatories, and Greenhouses; Churches, Public or Private Buildings, &c., with Cottam's Patent or Rogers's Boilers. After 15 years' experience, and having fixed upwards of 2000 Apparatus for the above-mentioned purposes, and by various improvements which they have made during that time, C. and H. can with confidence undertake the erection of similar Apparatus upon the most extensive scale.

Materials may be had for those who wish to fix their own Apparatus.

THE TANK SYSTEM on an improved principle, that will heat the house at the same time, without pipes.

IRON HURDLES, best Wire for Strained Fencing, Ornamental Iron and Wire-work, Garden Chairs, &c., &c., and every description of Implement for Agricultural and Horticultural Purposes.

Show Rooms at their Manufactory, 2, Winsley-street, Oxford-street, where a large assortment of the above can be seen.

GUANO (GENUINE PERUVIAN & BOLIVIAN) ON SALE, BY THE ONLY LEGAL IMPORTERS, ANTONY GIBBS AND SONS, LONDON; WM. J. MYERS AND CO., LIVERPOOL;
And by their Agents,
COTESWORTH, POWELL, AND PRYOR, LONDON;
GIBBS, BRIGHT, & CO., LIVERPOOL and BRISTOL.
47, Lime-street, Oct. 18, 1844.

WHEAT-SOWING.

GUANO; Genuine Peruvian, Bolivian, and Ichaboe, on Sale; also Potter's Guano, Gypsum, Sulphuric Acid, Sulphates of Iron and Copper, and all other manures. Synopsis of prices, and mode of use, on application, &c.—Apply to Mark Fothergill, 40, Upper Thames-street.

GUANO for SALE, in Bags of 1 cwt. each, just landed, with a succession of cargoes to arrive.—Successive years' experience has unquestionably proved that Genuine Guano is the simplest, cheapest, and best Manure within the reach of the Agriculturist. The only reasonable anxiety which now remains is to procure the Guano unadulterated, and to obtain such practical directions for using the Manure as shall fully develop its productive powers. To secure to buyers these indispensable requisites, with each purchase will be given a warranted chemical analysis of quality, and also a copy of the recently-published Pamphlet, "Practical Instructions for using Guano as a Manure, illustrated by Practical Results."

Large parcels will be delivered direct from the ship or waterside premises; smaller quantities may be had at the warehouses, 21 and 25, Billiter-street, or delivered within any reasonable distance at a trifling additional cost. Apply to James Clare, 24, Billiter-street.

TO COLONISTS, EMIGRANTS, &c. — Mrs. MARY WEDLAKE, widow of the late THOMAS WEDLAKE, at 118, Fenchurch-street, City, informs Emigrants and others that she continues to manufacture those Agricultural Implements for which her late husband was so extensively patronised by the Settlers of South Australia, Van Diemen's Land, Swan River, New Zealand, and other British Colonies. The following articles, made in a very superior manner, are kept on sale at the London Warehouse, viz.:—

Patent Hay-making Machines	Flour-Mills—Bean-Mills
Dressing Machines	Patent Essex Ploughs, 30 sorts
Patent Chaff-cutting Machines	Subsoil Ploughs [Colonies
Oil-cake Crushers	Threshing Machines for the
Double action Turnip-cutters	Drills of all kinds—Scarifiers
Railway Wheels	Vacuum Pumps.

Please to be particular in the address, Mary Wedlake, 118, Fenchurch-street, London.

POTTER'S GUANO MANURE is the only Guano that can positively be depended upon, and has stood the test of three seasons. The imported article, it is well known, is seldom twice alike, even when genuine, and is subject to a most extensive system of adulteration. Orders addressed early to the Works, 29, Upper Fore-street, Lambeth, will have instant attention. Testimonials will be sent per post, if required.

POTTER'S LIQUID GUANO may be had as usual of most Chemists and Seedsmen.

*** Beware of being imposed upon by ineffacacious imitations.

MR. LAWES' MANURES.—Mixture for Wheat, 4*l.* 7*l.* per ton; Super-phosphate of Lime, 7*l.* per ton. To be had at the Factory, Deptford Creek, near London.

Super-phosphate of Lime, in a concentrated form, may also be procured at Messrs. Warren's, 30, Cornhill, in 7 lb. packets, price 1*s.*

WHEAT-SOWING.

FREDERICK BRAIN begs to call the attention of the Agricultural world to his GUANO MANURE, prepared expressly for Wheat crops: it abounds in all the ingredients that are necessary for a good grain crop. He particularly solicits persons who found the Foreign Guano a failure last season to give him a trial, it being much more powerful, and free from adulteration, so justly complained of in the Foreign by Agriculturists, as well as by all the leading Agricultural Journals.

Testimonial to Brain's Guano Manure.—"5 A, Hawley Road, Kentish Town, London, Aug. 15, 1844.—This is to certify that we have subjected Brain's Guano to a most patient and rigorous analysis, and find it contains all the necessary constituents of a good manure, and is well calculated to give fertility to a soil which is either naturally barren, or has been exhausted by over-cropping, by supplying the land with those substances which are absolutely requisite to a healthy vegetation. (it is not adulterated, and can always be depended on, being of uniform composition.)—(Signed) John Mitchell and Frederick Field, Analytical Chemists, late of the Royal Polytechnic Institution, London."

Also, Brain's highly-concentrated LIQUID GUANO, for Grass Lands, Gardens, Shrubberies, Hothouses, and Conservatories, price 1*s.* 3*d.* per quart bottle, with full directions for use, (enough for 80 gallons of Liquid Manure), to be had of most respectable Florists, Seedsmen, and Chemists in town and country.

Works, Thomas-st., Duke-st., Stamford-st., Blackfriars-road.

IMPORTANT TO AGRICULTURISTS, &c.

ANALYSES of SOILS, MANURES, and all AGRICULTURAL PRODUCTS, are conducted by Messrs. Mitchell and Field (late Mr. Mitchell), Analytical Chemists, with the view of ascertaining whether the Soil, in which it is proposed to grow any particular crop, contains all that is necessary to produce a luxuriant vegetation; also to estimate the relative value and purity of Manures, and the comparative worth of Farm Produce in general. Gentlemen instructed in Agricultural Chemistry. The course will comprehend the Elements of Analysis.—No. 5 A, Hawley-road, Kentish Town.

DR. HALLETT'S DRY SOLUBLE FERTILIZER'S are, considering their power, the cheapest Manures in use, for they are entirely composed of the Phosphates and other Salts of Ammonia, and other acknowledged powerful fertilizers. They are fairly before the Public as tried things (see No. 33 of the *Gardeners' Chronicle, &c.*). 56 cwt. of either has been found equal to nearly 30 tons of ordinary horse-manure. They are applicable to all sorts of field and garden crops. No. 1 for heavy top growth, as Corn, Hops, &c. No. 2 is for all roots, and a sure preventive of the Fly in Turnips. Price of each, 10*l.* per ton, or 12*s.* per cwt.

Dr. Hallett's Concentrated Liquid Fertiliser is extensively used by Gardeners for improving the size and flavour of fruits and vegetables, and the colours, and perfecting the seed of flowers. Sold in quarts at 1*s.*, and in bottles, six times the size, at 7*s.* 6*d.* Each quart requires 32 gallons of water, to reduce it for use.

Agents for the above. London—Mr. Fothergill, Thames-street; Mr. G. Hallett, the Factory, Broadwall, Blackfriars; Messrs. Winstanly, Poultry; Pace and Co., St. Peter's Alley. Norfolk—Bullard and Watts, Norwich. Suffolk—Mr. W. Revans, Yoxford. Leicester—Mott and Co. Gloucestershire—Mr. Betterton, Fairford. Devonshire—Mr. Seward, Plymouth. Wilts—Mr. G. King, Devizes. Glasgow—Mr. D. L. Jackson, Hartlepool. Sunderland, Stockton, and Newcastle—Pace and Co. Dundee—Green and Co. Further respectable Agents wanted.

RAMS FOR RAISING WATER WITHOUT LABOUR, where a fall can be obtained. FOUNTAIN BASINS IN IRON, &c. 70, STRAND, LONDON.

F. ROE having purchased all the Patterns of Basins, Jets, &c. formerly belonging to W. Rowley, Fountain Maker to the Royal Family, is enabled to offer the above article in Iron, which will stand the Frost and last for ages. A Ram and Fountain Jets fixed on the premises for inspection. Every kind of Garden and other Pumps, Well Engines, Baths, &c. Houses, &c. Heated by Hot Water.

BY HER MAJESTY'S ROYAL LETTERS PATENT.

PATENT ASPHALTE ROOFING.

THE above Material has been used and approved by the Nobility, Gentry, and Agriculturists generally, as a Roofing and Covering to sides of Farm Buildings; its advantages are—Lightness, Durability, and Economy. Being a non-conductor, it has been proved an efficient Protective Material to Plants, and is now in use at the Royal Horticultural Society's Gardens, Chiswick. It can be had of any length, 32 inches wide, at 1*d.* per foot, super. A discount to the trade.

Thos. J. Croggon, 8, Ingram-court, Fenchurch-st., London.

TO LANDOWNERS, AGRICULTURISTS, BUILDERS, &c.

McKIBBIN'S Improved ROOFING FELT is peculiarly applicable as a substitute for Slate, Zinc, Tiles, and other articles used for Roofing, from its ECONOMY, LIGHTNESS, and DURABILITY.

The disadvantages attending other materials used in roofing, preventing, to a great extent, many useful houses and sheds being erected or rendered waterproof, it is submitted that the Improved Roofing Felt will in a great measure—and in some instances altogether—obviate them, and prove most serviceable from its lightness, durability, and impermeability to water and damp, in covering Houses, Cattle-sheds, Workshops, Ropewalks, &c., and for the sides, as well as roofs, of light structures for plants, being likewise a non conductor of heat; besides its economy in repairs, the timber where it is used may be so light as to save its whole expense; it requires no other coping, and may be applied by any person of common ingenuity; being flexible and portable also, it is free from breakage, the expense of carriage is inconsiderable in comparison with slates, tiles, &c., and it is not liable to contraction like zinc.

Sold in sheets 32 inches by 20, at 5*d.* each (being less than 9*s.* 6*d.* per square of 100 feet), with printed directions for applying them, same as adopted at the Government Dock-yards and various other public buildings.

Orders will meet with prompt attention if addressed to H. C. Bowden, 18, East India Chambers, Leadenhall-street, London, or to the following agents:—Liverpool, Messrs. Gruaber & Co., 11, Mancaster-lane; Plymouth, Thomas Stevens, Esq.; Birmingham, William R. Loyd, Esq.; Sunderland and Newcastle-on-Tyne, Messrs. John Ritson and Sons; Hull, William Ward, Esq.; Bristol, Messrs. Moor and Hewetts; Ramsgate and Deal, Messrs. Edward Hodges & Co.; Whitehaven, William Todd, Esq.; Glasgow, Malcolm Carmichael, Esq., St. Enoch-square; Cork, Messrs. Richard Willis & Co.; Belfast, Messrs. Greeber & Co., Dunbar's Dock; who have also on sale McKibbin's improved SHEATHING, BOILER, RAILWAY, and other FELT.

*** The "Improved Roofing Felt" will be found much more durable than the Common Felt made in lengths, and not subject, like it or continuous sheets of other material, to be stripped by storms; it can also be more easily repaired, and from the simple mode of application recommended, the wet cannot percolate through nail-holes, being only fastened down at the overlaps.

THE WORKS OF G. P. R. JAMES, ESQ.

On the 1st October was published, the original volume of the NEW and ILLUSTRATED EDITION of these WORKS, comprising the whole of the celebrated Historical Romances

MARY OF BURGUNDY,

This new and attractive series commenced on the 1st July with "THE GIPSY," (of which a second volume has since been required.) SAVORY and SONS, No. 9, Cornhill, London, opposite the Bank of England, invite attention to a splendid variety of Rosewood, China, Bronze, and Ormolu CLOCKS; they go for eight days and strike the hours and half-hours. Price 4 guineas, 7 guineas, and 10 guineas each, and upwards. The performance is warranted.

A Pamphlet, with detailed lists of Prices, and illustrated with sketches, may be had on application gratis, or sent to all parts of Great Britain and Ireland, postage free, in answer to a post letter.

TERRA COTTA FIGURES, VASES, FOUNTAINS, &c. Manufactured by DOULTON and WATTS, LAMBETH POTTERY High-street, Lambeth, London.

D and W., from their experience as Potters, have made considerable improvements in the manufacture of Terra Cotta, the superiority of which over Artificial Stone or Cement is well known. It is subjected to a high degree of fire, which renders it imperishable, and gives it a sharpness and surface which no changes of temperature can impair.

D. and W. are enabled to offer the Terra Cotta at a considerable reduction in price; and Drawings and Designs will be forwarded Gratis, on application.—Architectural work executed.

LEA AND PERRINS'S WORCESTERSHIRE SAUCE Prepared from the Recipe of a Nobleman in the County.

"*Great Western Steam-ship, June 5, 1844*—The cabin of the Great Western has been regularly supplied with LEA & PERRINS'S Worcestershire Sauce, which is adapted for every variety of dish, from turtle to beef, from salmon to steaks, to all of which it gives a famous relish I have great pleasure in recommending this excellent Sauce to Captains and Passengers for its capital flavour, and as the best accompaniment of its kind for a voyage (Signed) JAMES HOSKEN."

"One of the most piquant inventions of this luxurious and epicurean age is Lea and Perrins's Worcestershire Sauce, adapted to fish, flesh, fowl, and soup; giving a zest far superior to the long established favourites; more wholesome and of less cost."—*Naval and Military Gazette*, April 6, 1844.

Sold Wholesale by the Proprietors, Messrs. LEA and PERRINS, Worcester; Messrs BARCLAY and SON, Farringdon-street; and the principal Oil and Italian Warehousemen in London; and Retail by the usual venders of Sauces.

LITERARY LEAVES; or, Prose and Verse. By DAVID LESTER RICHARDSON

2 vols. 8vo, Second Edition, price 12s.

"We strongly recommend this second and enlarged edition. We can easily imagine how such writings as these, appearing from time to time in the Indian journals, must have gratified the English residents, since even here, in the midst of lions and new books, we run over the leaves with unmixed pleasure"—*Atlas.*

"His poetry derives, from his unfeigned attachment to home, a very touching beauty. Most persons who have been long absent from the place of their birth know how delicious is the feeling with which it is approached Mr Richardson describes this feeling with exquisite truth and tenderness . . . Whatever forms of nature challenge his preference, he views them all with a poetical eye, and paints them in his verses with vividness and fidelity We should be glad to see the poetry of these volumes detached from the prose, and sent into the world alone. It has sufficient character in it to depend on its own vitality; and we venture to predict that it will live"—*Sunday Times*

"The essays afford some exquisite reading We can with perfect confidence refer every man of literary taste to these volumes, which we consider as elegant and valuable contribution to the literature of our country"—*Indian News*

"The poems are largely impregnated with Nature's best and holiest feelings. They are utterances of the writer's own heart, and they touch the hearts of his readers. They leave an impression which will not be easily or speedily effaced. The diction is in keeping with the sentiments, it is at once accurate and graceful The same observation applies to the author's prose writings"—*Observer.*

SMITH, ELDER, AND Co., Cornhill, London

MR HOARE'S NEW WORK ON THE VINE.

Just published, 12mo, 7s cloth,

A DESCRIPTIVE ACCOUNT OF A NEW METHOD OF PLANTING AND MANAGING THE ROOTS OF GRAPE VINES By CLEMENT HOARE, Author of "A Treatise on the Cultivation of the Grape-Vine on Open Walls"

SGIRLING begs to refer the Readers of the *Gardeners' Chronicle* to his Advertisement of PETUNIAS, SEEDLING VERBENAS, DAHLIAS, &c., of the 12th October. Dancecroft Nursery, Stowmarket, Suffolk.

T. THOMSON begs to inform the Cultivators of the PANSY he is now sending out strong Plants of his New Seedlings, including Pizarro and all the principal leading varieties in cultivation, at moderate prices.—Iver, Oct. 25, 1844.

NEW AND SUPERIOR SEEDLING PELARGONIUMS, RAISED by E. FOSTER, Esq., the Rev. R. GARTH, and Mr. COCK.

W. CATLEUGH begs respectfully to call the attention of Cultivators to the following Seedlings, of which W. C. has the Stock to let out, viz.:—

(2) Robustum		42*s.* 0*d.*	(2) Nabob		42*s.* 0*d.*
Magician		21 0	Vixen		21 0
* Miss Peel		42 0	Shield of Achilles		21 0
Lady Hewick		42 0	* Duke of Devonshire		42 0
* Dr. Lindley		42 0	The Cid		21 0
* Phœon		42 0	Oddity		21 0
Rosetta		42 0	Sultana, or Perpetual		10 6

The above splendid Seedlings were raised by E. Foster, Esq.; those marked (2) have gained two prizes, those marked * one prize at the London Horticultural Society or the Royal Botanic Society, and were universally admired, as being new in character, firm in texture, brilliant and distinct colours.

The following were raised by the Rev. R. Garth, but have never been exhibited.

Adela		42*s.* 0*d.*	Lightning		10*s.* 6*d.*
Anna Boleyn		21 0	Mary		21 0
Apollo		10 6	Magog		42 0
Blood Royal		10 6	Nabob		10 6
Cinderella		21 0	Nameless		42 0
Diadem		42 0	South Western		42 0
Gipsey Queen		21 0	Seduisante		21 0

The following splendid Seedling was raised by Mr. Cock; it is a fine bold flower, and obtained one prize at the Royal Botanic Society:—Hector, 21*s.*

NEW AND SPLENDID CARNATIONS.

W. C. has the entire Stock of the following splendid Scarlet Flake, raised by Mr. Low, to let out:—

Catleugh's Lady Broughton, 21*s.* per pair.

The following fine Seedlings were raised by J. L. Puxley, Esq:

Prince of Wales (purple flake), 21*s.*
Princess Alice ditto 21*s.*
Princess Royal, the finest rose flake yet out, 21*s.*

And other good Seedlings raised by the above gentleman.

C. D. Jersey, Esq.'s fine Seedling Yellow PICOTEES—Beauty, Favourite, La Superbe, Queen.

W. C. has the entire stock raised by the above gentleman to let out.

W. C.'s Catalogue is now ready of first-rate Geraniums, Azaleas, Fuchsias, Roses, Carnations, Picotees, Pinks, Auriculas, Verbenas, &c. &c.

Hans-street, Sloane-street, Chelsea.

TO CUCUMBER AND MELON GROWERS.

ROBERT COOPER, Slon Nursery, Croydon, will forward the under-mentioned varieties of Cucumber and Melon Seeds, post-free, on the receipt of a post-office order payable at Croydon, or postage stamps to the amount.

VICTORIA CUCUMBER, 1*l.* 1*s.* per packet of three seeds, white spine, dark-green colour, short stick neck, very strong bloom, robust grower and prolific bearer; grows from 28 to 34 inches long. N.B.—A seed fruit can be seen at the above Nursery.

MILLS'S JEWESS CUCUMBER, 2*s.* 6*d.* per packet of five seeds; STEWART'S RINGLEADER DO., 2*s.* 6*d.* *dd.*; NEWSUM DO., 1*s.* 6*d.* do.; a handsome black spine fruit, about 18 inches long; an abundant bearer.

HOGSARTH MELON, 2*s.* per packet of five seeds; IMPROVED GREENFLESH DO., 1*s.* do.

JOHN SLATER, FLORIST, Cheetham Hill, near Manchester, respectfully calls the attention of the Horticultural Public to his large and select collection of the following Florists' Flowers:—TULIPS, AURICULAS, POLYANTHUSES, CARNATIONS, and PICOTEES; catalogues of which may be had on prepaid application. 12 plants of named Auriculas, all different varieties, for 20*s.*, package included. 12 plants of Carnations and Picotees, good named varieties, for 20*s.*, package included.

THE TRUE FASTOLFF RASPBERRY.

GREAT YARMOUTH NURSERY. NORFOLK, 1844.

PATRONISED BY HER MOST GRACIOUS MAJESTY THE QUEEN, HIS GRACE THE DUKE OF RUTLAND, THE EARL OF HARRINGTON, THE EARL OF LIVERPOOL, THE LORD BISHOP OF LONDON, LORD VISCOUNT LORTON, LORD SONDES, &c. &c.; as well as by the HORTICULTURAL SOCIETY OF LONDON.

YOUELL & CO. have much pleasure in announcing they are enabled to supply fine Canes of the above highly valuable and much esteemed Raspberry, unequalled for the extraordinary size of its fruit, and richness of flavour.

Those to whom Y. and Co. sent it last season have expressed their high admiration of its superiority over all other varieties, and have been awarded several prizes at various Horticultural Exhibitions during the season. As a proof they have not exaggerated its excellent qualities, Fruit was submitted to Dr. LINDLEY (see *Gardeners' Chronicle* of the 27d July, 1843, p. 503), whose opinion of it is as follows:—

"FASTOLFF RASPBERRY.—We have received from Messrs. YOUELL, of Great Yarmouth, fruit of the Fastolff Raspberry, and we find it merits all that has been stated in favour of its excellence. The fruit that we have received is very large, obtusely conical, and of rich flavour, far exceeding in this respect some other new and large varieties. The plants bear abundantly, and in long succession."

They also exhibited it on the 1st of August, 1843, before the London Horticultural Society, 21, Regent-street, to which a prize was awarded; and again at the Horticultural Society's Exhibition at Chiswick, July 13, 1844, and maintained its high character, by having a Certificate of Merit awarded it. It would therefore be unnecessary for YOUELL and Co. to recommend it more fully, or with greater confidence to the notice of the public, merely observing that it continues in high perfection throughout the autumnal months (vide *Gardeners' Chronicle*, 19th inst., page 703), and has maintained its superiority in the most unfavourable soils and situations, and requires no other than the ordinary treatment of the old varieties.

Fine Canes are ready for delivery, and can be sent with safety to any part of the United Kingdom upon the following terms:—

Packages containing 100 Canes		£2	0	0
Ditto	50	1	1	0
Ditto	25	0	12	0

Package included.

YOUELL and Co. feel it due to themselves to state that a spurious kind was offered for sale by other parties last season, under the title of "Fastolff Raspberry," the same having no pretensions to the genuine variety; and to obviate a repetition of the like they have appointed the following Nurserymen and Seedsmen as their Agents for the sale of it, at whose establishments may be seen engravings of the Fruit:—Bury St. Edmunds—Mr. R. Pettit; Canterbury—Mr. W. Masters; Carlisle—Messrs. Little and Ballantyne; Chichester—Messrs. Newman and Co.; Cliff Vale, near Leek, Staffordshire—Mr. F. Fox; Cork—Messrs. Hayeroft; Doncaster—Mrs. Milan, Seed-shop; Dundee—Messrs. Urquhart and Son; Durham—Messrs. Hancock and Sons; Edinburgh—Messrs. Peter Lawson and Son; Fulham—Messrs. Whitley and Orchorn; Glasgow—Messrs. Drysdale and Co.; Haddington—Mr. T. Dods; Halifax—Mr. W. Throp; Jersey—Mr. B. Saunders; Leeds—Messrs. Ely and Son, Rothwell Haigh; London—Messrs. Flanagan and Son, No. 9, Mansion House-street, and Messrs. Noble, No. 152, Fleet-street; Liverpool—Mr. James Cuthbert, 12, Clayton-square; Manchester—Mr. H. D. Cormack; Nottingham—Mr. J. P. Wood, The Coppice; Peterborough—Mr. John White; Penzance—Mr. J. Fox; Plymouth—Mr. W. E. Randle; Sheffield—Messrs. Fisher, Holmes, and Co.; Southampton—Mr. James Ingram; Stafford—Mr. J. Sandy; Torquay—Mr. J. Morgan; Wakefield, Mr. W. Barratt; Waterford—Messrs. Fennessey and Son; Wexford—Mr. James Harpur; York—Messrs. T. and I. Backhouse.

YOUELL'S CELEBRATED TOBOLSK RHUBARB, the earliest sort known; fine roots, fit for forcing, 12*s.* per dozen.—Great Yarmouth Nursery, Oct. 24, 1844.

WOODLANDS NURSERY, MARESFIELD, NEAR UCKFIELD, SUSSEX; and at PARIS.

WILLIAM WOOD AND SON beg leave to offer their extensive Stock of CAMELLIAS, fine Stocky Plants, well furnished with Flower buds, at the following prices, the selection of Sorts being left to themselves.

Good and Esteemed Varieties	.	30*s.* per dozen.
Superior Selected do.	.	45*s.* ,,
Superb New do.	.	60*s.* ,,

Also a Superb Collection of all the best and newest CINERARIAS, fine Bushy Plants, well adapted for flowering during the winter months.

Very fine Varieties	.	6*s.* per dozen.
Superior Selected do.	.	12*s.* ,,
Superb New do.	.	18*s.* ,,

Plants will be presented to compensate for carriage. Catalogues of the above; also Lists of W. W. and Son's Collection of FUCHSIAS, VERBENAS, Greenhouse and Herbaceous Plants, may be had *gratis* on application.

Woodlands Nursery, Oct. 25.

SPLENDID NEW SCARLET FLAKE, "STEPHENSON'S HARRIOT."

JOHN STEPHENSON begs to announce to the cultivators of the Carnation, that he has now ready for sending out good healthy plants of the above Seedling, which he does with the utmost confidence recommend for brilliancy of colour, purity of white, and regularity of flake, to be decidedly superior to any flowers of that class.

A Bloom was exhibited at the open Show held at the Coppice, Nottingham, and placed for the *first prize*, (which prize was withheld because it was not entered in due time.)

The following notice appeared in the *Chronicle*, Sept. 14, in allusion to this Seedling:—"The Scarlet Flake was also a *fine* white good high colour, the petals of good texture, and well rebonded."—10*s.* per pair.—A remittance or reference required.

Palmer-lane, York, Oct. 22.

GERANIUM "CELESTIAL."

CHANDLER AND SONS, NURSERYMEN, Vauxhall, London, have now ready to send out young plants of their New Geranium "CELESTIAL," which has been so much admired. The flowers being very large, and with a beautiful white throat, it is one of the most conspicuous varieties that has yet been raised. Plants, 10*s.* 6*d.* each.

C. and Sons have also to offer healthy young plants of CAMELLIAS of sorts with flower-buds, at 36*s.* per doz.; larger plants, 42*s.* per doz.; and good plants of the newer sorts, 60*s.* per doz. Also good plants of the best sorts of CHRYSANTHEMUMS, at 12*s.* per doz; larger plants, 18*s.* per doz. The package included in the above prices. A remittance or reference for payment in London will be expected from unknown correspondents.

AGRICULTURAL CHEMISTRY.

RICHARD GRIFFIN & CO., CHEMICAL MUSEUM, Buchanan-street, Glasgow, respectfully call the attention of Agriculturists to the following publications:

1. SIR HUMPHREY DAVY'S COURSE OF LECTURES ON AGRICULTURAL CHEMISTRY. A New Edition, with full Instructions for the Analysis of Soils, and Copious Notes embracing the recent discoveries in this Science. By JOHN SHIER, A.M., Fordyce, Lecturer on Agriculture in the University of Aberdeen. One Vol., 8vo., many figures, 9*s.* cloth.

2. DESCRIPTIVE CATALOGUE of all the Chemical Apparatus and Tests requisite for the Analysis of Soils and Manures, with 62 Engravings. Gratis.

3. DESCRIPTIVE CATALOGUE of a Cheap Set of Chemical Apparatus. Price 21*s.* 6*d.* Adapted for use in Schools where Agricultural Chemistry is taught. Gratis.

The Advertisers undertake to supply all kinds of Chemical Apparatus and pure Tests for Analytical purposes, of the most effective kind, and at moderate prices.

JESSOP'S NURSERY, Cheltenham, Established in 1815, from its extensive connection offers peculiar advantages to Noblemen and Gentlemen requiring Gardeners, Foresters, or Farm Bailiffs, of established skill and reputation. All communications promptly attended to.

ROSES.

H. LANE AND SON'S CATALOGUE OF ROSES for 1844 42 may be had on application to the NURSERIES, GREAT BERKHAMPSTED, HERTS., inclosing a 2*d.* Stamp. The Catalogue is considerably condensed this season by the omission of many old but well-known and valuable varieties, in order to bring it within the limit of the 2*d.* post charge.

Messrs. LANE and SON beg with confidence to solicit the attention of their friends to their immense collection of ROSES IN POTS; at the same time to observe, that upon reference to the Awards of Prizes by the Horticultural and Royal Botanic Societies of London during the last season, it will fully appear that they are the most successful cultivators of Pot-Roses in the kingdom. They also beg to add, that in consequence of the late favourable autumn their Standards and Dwarfs of the Hardy sorts of Roses were never stronger or better grown than they are this season.—Oct. 25.

CARNATIONS AND PICOTEES.

JOHN DICKSON, Acre-lane, Brixton, Surrey, has prepared for the growers of these splendid flowers a Catalogue, enabling them to judge of their qualities, with the prices annexed, which may be had at the Nursery, and of Messrs. WARNER & WARNER, Cornhill, London, after the 7th September.

JOHN CATTELL has now ready to send out two SEEDLING CINERARIAS, viz., Hero of Westerham, 5*s.*, —the richest coloured yet sent out. The following is an extract from the *Gardeners' Chronicle* of April 27th:—"J. C.—Your seedling Cineraria is very attractive; the crimson centre with mazarine-purple termination to the petals is of the richest colours, the petals are rather narrow, but the flower is a good size, and most brilliant and beautiful in colour." And Prince of Wales, 5*s.*; centre blue, petals round the centre white, terminating with a beautiful bright deep blue, and excellent shape. These Cinerarias are strong growers, and of shrubby habit. No collection ought to be without them.

Also two SEEDLING ACHIMENES, viz., Rosea coccinea, 5*s.*—the colour as fine scarlet as the old Coccinea, in growth as strong and more bushy than Rosea, and blooms as early—and Atro-Rosea, 3*s.* 6*d.*, an improvement on Rosea. These two varieties will be found very useful for the June and July Shows; also for growing in small pots. Plants in 48 size pots have been loaded with flowers all the summer; while Coccinea, under the same treatment, only began to flower late in September.

The above can be sent by post. A remittance is expected from unknown correspondents.

J. C. begs to call the attention of the public to his fine stock of superior-grown Standard and Dwarf Roses, which are not surpassed, if equalled, by any other grower; a Catalogue of which may be had on application by inclosing a penny stamp. Also his usual extensive stock of Fruit and Forest Trees, Shrubs, Quick, &c., most particularly of transplanted large and small Laurels, Spruce Fir of all sizes, Hollies, Privet, Yews, Lilacs, and Laburnums; also Ash, Chesnut, &c., for underwood; Larch for Hop-poles, &c.—Westerham, Oct. 24th.

J. D. PARKS begs to announce that he has now ready for Sale a fine variety of LABURNUM INTERMEDIUM. Branches and racemes very long; habit very robust, and vigorous; flowers deeper yellow than the common, something later, and very sweet-scented. Dr. Lindley highly recommends it. Fine Seedling Plants at 4*s.* 6*d.*; Dwarf Plants, at 3*s.* 6*d.*

Fine LAURELS, 5 feet high; do HORNBEAM, 9 feet or upward; do. YEWS, at 9*d.* per foot in height; do. WEEPING ASH, at 2*s.* 6*d.*, tall stems. Best varieties of Apples at 1*s.*; Trees very strong. Laurustinus and Portugal Laurels, large Plants.—Dartford Nursery, Dartford, Kent, October 24.

NEW PROVIDENCE PINE PLANTS.

ON SALE.—100 good Succession of the above valuable sort, warranted free from White Scale and Mealy Bug. For particulars apply, prepaid, to JOHN BUTCHER, Nurseryman, Stratford-on-Avon.

TO THE LOVERS OF ROSES.
WOODLANDS NURSERY, MAIDSTONE, NEAR UCKFIELD, SUSSEX, AND AT PARIS.

WILLIAM WOOD AND SON have the honour of submitting to the notice of their Friends and Amateurs, the much-admired truly magnificent Gallica Rose; it has flowered here this season in great perfection, and blooms were forwarded to Dr. LINDLEY, whose opinion appeared in the *Gardeners' Chronicle*, page 564.

MARGARET MARY (Wood's).—"Your seedling, Gallica, is a handsome variety, fine in form, being compact and very double, outside petals finely cupped; its colour is of a purple rose, of a peculiar and beautiful tinge; it is fragrant, and at its best when fully expanded."

Plants of the above are now ready for immediate delivery. Standard and Dwarf at 5s. each. The usual discount to the trade when not less than six plants are ordered at once.

W. W. and Son further beg leave to state that they have on hand a very extensive stock of Roses, at the following prices, when the selection is left entirely to them:—

	Per doz.	Per 100.
Superior selected standard Roses	21s.	£ s. d.
Superb do. do.	30 or 10	0 0
Select dwarf budded do.	12 —	3 15 0
Superb do. do.	18 —	5 0 0
Superior dwarf Roses (on own roots)	9 —	2 10 0
Superb do. do. fine show varieties	12 —	3 15 0
Rose Creeping do.	9s and 12 —	2 10 0

Cottage Roses and Nursery Stock will be sent gratis on application.

N.B. Plants will be presented GRATIS, in order to compensate the expense of carriage. A remittance, or reference, will be required from unknown correspondents.

TULIPS, HYACINTHS, RANUNCULUSES, ANEMONES, GERANIUMS, AURICULAS, CARNATIONS, and LILIUM LANCIFOLIUM.

H. GROOM, Clapham Rise, near London (removed from Walworth), by Appointment FLORIST TO HER MAJESTY, begs to recommend to the attention of the Nobility, Gentry, and Public his extensive assortment of the above Flowers which, from the success he has had in their cultivation, he can offer at very moderate prices. He particularly wishes to call attention to the highly-flattering remarks on his Exhibitions of Tulips and Lilium lancifolium this season, in the various papers. He is also desirous of reminding the Nobility, Gentry, and Amateurs, who may wish to add to their collections or ornament their parterres with these beautiful flowers, that this is the best season to make a selection. The varieties of the splendid Lilium lancifolium are particularly adapted for parterres, as, besides being quite hardy, they flower at a time when the Nobility and Gentry are at their country seats, and when flowers are so much wanted. They only require to be known to be universally cultivated. Catalogues can be forwarded by post on application. Foreign orders executed.

THE GREATEST NOVELTY EVER OFFERED TO THE PUBLIC.

RHODODENDRON JACKSONII.—This splendid new hardy Rhododendron is confidently recommended as the most beautiful variety extant; it surpasses in the colours of its flowers the richest Geranium, and is quite a new feature in this noble family. It forces well, is a free bloomer, and of a dwarf habit. A truss of flowers was transmitted to Dr. Lindley, who pronounced it "a very compact and handsome variety," with "great richness" in its general appearance, &c. See *Gardeners' Chronicle* of the 6th April last, page 216, "*Rhododendron*.—*C. L. N.*" To be sent out in March at 10s. 6d. each.

Wm. Jackson and Co. beg also to call the attention of the Nobility, Gentry, and the Trade to the following rare and valuable Rhododendrons, all warranted true, at the very low prices attached. The plants are from seed, fine and stout, before transplanted, and ready to send out.

Rhododendron campanulatum, averaging 1 inch 3*l*. per 100.

HYBRIDS

Between R. campanulatum and the scarlet arborea, 2 in., 3′, p.	100	
" " " maximum	3*l*.	"
" " " nivalcum, 1 inch	7*l*. 10*s*.	"
" " " Catawbiense, 1 inch	7*l*. 10*s*.	"

Usual Discount to the Trade on the above.

Primula Celestial, No. 1, 2*s*. 6*d*. each; do. Fairy, No. 2, 2*s*. 6*d*. each; fine plants well established. See Dr. Lindley's opinion in the *Gardeners' Chronicle* of April 6th, page 216, under the letters "C. L. N.," and Advertisement of Aug. 24th.

Their new Catalogue is now ready (in which is a list of their fine white and scarlet Rhododendrons), and may be had on application. A remittance or reference will be expected from unknown correspondents.

Agents in London: Messrs. WHITLEY and OSBORN, Upham Nursery, who have seen the plants.

Cross Lanes Nursery, near Bedale, Yorkshire, Oct. 25.

HERTFORD NURSERIES.

E. P. FRANCIS begs respectfully to inform the Nobility, Ladies, and Gentry, that his descriptive CATALOGUE OF ROSES is now ready for delivery, and will be forwarded gratis upon application, and which comprises upwards of a thousand varieties.

E. P. F. takes this opportunity of stating that he has made an addition of several acres of land, and that his Nurseries now extend over 25 acres of ground, containing a large stock of Fruit and Forest Trees, which are in fine and healthy condition; a fine assortment of Trained Trees, Evergreens, and Flowering Shrubs, all of which may be had upon the most reasonable terms. Catalogues may be obtained with Prices attached. Carriage of all goods paid to London.

TRAINED PEACHES AND NECTARINES.

WM. E. RENDLE respectfully informs the Nursery Trade that he has this season a large stock of TRAINED PEACHES AND NECTARINES, strong, healthy, and in excellent condition.—Union Road Nursery, Plymouth, Oct. 25, 1844.

GERANIUMS AT VERY LOW PRICES.

WM. E. RENDLE, having a large stock of the following sorts of GERANIUMS, is enabled to offer them at very low rates.

*** A dozen will be forwarded on receipt of a Post-office order, including hamper, package, and carriage free to the London Terminus of the Great Western Railway.

CLASS 1.—3*s*. per dozen, including package, carriage, &c.—Conflagration, Pulchellum, Jersey Maid, Lady Villiers, Fascinator, Lucrece (double), Symmetry, Thunderer, Dido, Cordelia, Gloire, Favourite, Prince of Waterloo, Jessie, Count D'Orsay, Lord Rancliffe, Castellati n, Lavinia, Cornish Gem, Attila, Duchess of Cornwall, and Senator.

CLASS 2.—2*s*. per dozen, including package, carriage, &c.—Regina, Gipsey, Witch, Hamlet, Cynthia, Aurora, Creole, Lady Golden Sheppard, Countess of Mount Edgcumbe, Fair Maid of Devon, Wonder of the West, Portia, Jupiter, Life-guardsman, King John, Rullan, and Princess Royal (Lyne).

CLASS 3.—18*s*. per dozen, including package, carriage, &c.—Camilla, Coronet, Van Amburgh, Enchantress, Glory of the West, Hendon, Flash, Queen of the Fairies, Grand Monarch, Amethyst, Wildfire, Isabel, Prince Albert, Nymph, Bridegroom, and Sybil.

All the plants are strong, healthy, and well established, and will be forwarded immediately on receipt of order.

Union Road Nursery, Plymouth, Oct. 25, 1844.

A SPLENDID NEW LATE PEACH.

MORTON'S "WALBERTON ADMIRABLE."—This splendid variety was raised at Walberton House, in Sussex, the seat of R. Prime, Esq. It is a Seedling from the Noblesse, which it much resembles, both in size and colour. It possesses all the fine qualities of its parent, but its great merit arises from its ripening full five weeks later. A specimen of its fruit was sent to Dr. LINDLEY in 1841, from whom were received the highest testimonials of approbation. The tree is a fine, free, and hardy grower; the fruit is full-sized, melting, and excellent-flavoured, rendering it a truly desirable variety, and one which no good garden ought to be without. Good one year's trained plants can be obtained of ALEXANDER WEBB, Nurseryman, Westergate, near Arundel, Sussex; at Messrs. HAY, ANDERSON, and SANGSTER'S, Newington Butts; and also at Messrs. HOGGE and M'MULLEN'S, 6, Leadenhall-street, London, at 10*s*. 6*d*. each; a few strong plants at 15*s*. each. The usual allowance to the Trade when three or more are taken, and carriage paid to London. Remittance from unknown correspondents is required.

TO THE PLANTERS OF ENGLAND.—TRUE HIGHLAND PINE.

JAMES GRIGOR, NURSERYMAN, Norwich, begs to remind such of the Planters of England as are anxious to enhance the beauty and value of their estates, that he is now sending out plants of this recently introduced and very desirable timber-tree, at the undermentioned prices:—

Single plants, strong and well rooted	6*d*. each.
Strong plants, 20 inches high	5*s*. per 100.
Do. 18 "	30*s*. per 1000.
Smaller-sized plants from 10*s*. to 20*s*.	"

For introducing this tree Messrs. GRIGOR, of Elgin and Forres, were awarded several premiums by the Highland and Agricultural Society of Scotland, where it is rapidly superseding the common Pine. In its old age it assumes in a great measure the darksome grandeur of the Cedar of Lebanon, and is therefore invaluable for planting in masses throughout the more prominent parts of distant landscapes. Sir Walter Scott describes it as presenting much of "the bold and contorted figure of the Oak;" and the *Quarterly Review* recommends it as an acquisition to churchyards and cemeteries. It is highly esteemed for all economical purposes, on account of the hardiness and durability of its wood.

N.B.—J. G. has for the present disposed of all his potted plants; but as the others have excellent roots, there is no risk in removing them. A supply in pots will be ready in the course of next month.

CEDRUS DEODARA, raised from seeds in the open ground, 10*s*. each. Araucaria imbricata, Pinus excelsa, &c. &c. on reasonable terms.

DOUBLE ROMAN and PAPER-WHITE NARCISSUS, 4*s*. per dozen. The above Bulbs, the former of which is so justly esteemed for its early blooming and excessive fragrance, and the latter for its purity and elegance, have been just received at A. CORBETT'S, late Mr. BARRON'S, Italian and Foreign Warehouse, 18, Pall Mall. Also Dutch Hyacinths, Crocus, Tulips, Anemones, &c. &c. Price Catalogues of which may be had per Post.

TO TULIP GROWERS.—About 1500 TULIPS of first-rate quality, and all named flowers, are now offered at full 50 per cent. lower than they could be purchased in the ordinary way of trade. Owing to the numerous avocations of the Advertiser, they are at present mixed, but the purchaser would have no difficulty in assigning their names when in bloom.—Apply to E. CATLING, Florist, &c., Cambridge.

THE NEW AND SUPERB SEEDLING PICOTEE, "BURROUGHES'S DUKE OF NEWCASTLE."

For particulars of the above, see YOUELL & Co.'s Advertisement of October 12th.

YOUELL AND CO. are also enabled to supply the following superb Picotees, raised by the same gentleman, all possessing first-rate properties, and have been exhibited and obtained first-class prizes at several of the metropolitan Exhibitions of the present year. They are as follow:—

Burroughes's Mrs. Benyon, Red Picotee	7*s*. 6*d*.
" Lady Alice Peel, Rose Picotee	7 6
" Miss Jane, Purple Picotee	7 6
" Mrs. Bevan, Red Picotee	7 6
" Enchantress, Scarlet Picotee	5 0

CARNATIONS AND PICOTEES.

Y. and Co.'s collection of this beautiful tribe of flowers will be found the most extensive and select in Europe, comprising every known variety of merit. The plants are remarkably strong and healthy, and ready for sending out to any part of the United Kingdom and the Continent at the following prices:

		£ s. d.
12 pairs extra fine and very superior first class Show Flowers		2 10 0
25 ditto ditto ditto		5 0 0
12 ditto ditto Show Flowers		1 10 0
25 ditto ditto ditto		3 0 0
12 pairs of Extra fine Show Pinks		0 12 0
25 ditto ditto ditto		1 1 0

The selection being left to Y. and Co.

*** For Particulars of their finest imported DUTCH HYACINTHS, &c., see their Advertisement of Oct. 12.

Great Yarmouth Nursery, Oct. 21.

TO CULTIVATORS OF VINES.

ALEXANDER RUSSELL, GARDENER, Turnham Green, begs to inform his Friends and the Public generally that he has for Sale a few dozens of Black Hamburgh VINES in Pots, grown from eyes last spring; wood strong, well ripened, and eyes fully developed, and cannot fail to insure a good crop next season, if forced in the pots. To prevent disappointment, early applications will be necessary. Price 5*s*. each.

FUCHSIA "EDINA."

JAMES DICKSON AND SONS beg to inform their Floricultural friends that they will send out early in spring strong plants of the above hand-some and showy Fuchsia, which was so much admired during the past season at all the Horticultural Shows at which it was exhibited. Dr. Neill then described it as "remarkable for the size of its flowers;" and its form and colour, as well as habit of plant, are also of a very superior description. Plants, 7*s*. 6*d*. each, postage included.—Inverleith Nurseries, Edinburgh, Oct. 1844.

PLANTS WANTED.

EVERGREEN OAKS in Pots 3 to 5 feet; Common YEWS, 2 to 3 feet; Canadian HOLLIES, 2 to 3 feet; Common Firs in Pots, 2 to 3 feet; Euphenrum fruticosum, and Variegated HOLLIES; they must be good plants, with prices and every particular.—Address immediately to WILLIAM MILLER, Providence Nursery, Ramsgate, Kent.

CHOICE HYACINTHS AND OTHER DUTCH BULBS.

CLARKE AND CO., SEEDSMEN AND FLORISTS, beg to inform the Nobility, Gentry, and the Public, that their Collection of the above ROOTS have come to hand in very excellent condition this season. Early orders will insure good roots, and to which every attention will be paid. Catalogues will be forwarded Post-free on application.

100 Choice selected Hyacinths, (either for pots or glasses,) in 50 beautiful named sorts . . 2 10 0.

N.B.—Any Roots purchased or ordered, if not approved of, or found to be unsound, will be exchanged.—The Trade supplied.

56, High-street (opposite the Town-hall), Borough, London.

RICH LEAF-MOULD and PEAT-EARTH.—Several acres of valuable Peat-earth and Leaf-mould of a rich quality, to be disposed of. Gentlemen and Nurserymen engaged in the Cultivation of Heaths and American Plants will find the above articles of a very superior kind. They will also be found of great value as dressings upon strong lands.—For full particulars apply to Mr. LAWRENCE, Corn Chandler and Seedsman, No. 15, Piccadilly.

HOTHOUSES, CONSERVATORIES, &c., made and fixed Complete in all parts of the Kingdom. One, two, and three-light Cucumber and Melon-Boxes and Lights of all sizes kept ready for immediate use, packed and sent to all parts of the Kingdom; warranted best material. Two-light Boxes and Lights complete, from 1*l*. 6*s*. Garden-Lights made and glazed from 1*s*. per foot, at JAS. WATTS'S Sash Manufactory, Claremont-place, Old Kent-road. *** References given.

SLATE WORKS, ISLEWORTH, MIDDLESEX.

THE following Articles, manufactured in Slate for Horticultural purposes, may be seen in use at Worton Cottage, upon application to the gardener (Sundays excepted).

Tank Covers	Bottoms for Frames
Cisterns	Boxes for Balconies and Verandahs
Shelves	
Garden Edging	Orange Tubs; Flower Boxes, &c.

EDWARD BECK will be happy to answer any inquiries, either personally or by post.

Sales by Auction.

EXTENSIVE SALE OF NURSERY STOCK.

MESSRS. PROTHEROE AND MORRIS beg to announce they have received instructions to sell by Auction, on the Premises, Windmill-lane, Camberwell, on Monday, 28th of October, 1844, and following days, at Eleven o'clock, a most valuable and varied collection of Hardy Trees, Shrubs, American Plants, Evergreens, blooming Camellias, Ericas, &c. Amongst the stock will be found some fine bearing Mulberries, and several hundred of fine straight young plants of ditto. There are also fine Magnolias of sorts, strong Vines in pots, Climbing and other Roses, a first-rate collection of choice American Plants, and other valuable Shrubs, affording a most eligible opportunity for Nurserymen providing themselves with healthy stock. A portion of the American Plants, Shrubs, &c., will be lotted in varied collection to suit all customers. Catalogues may be had of the principal Seedsmen, and of the Auctioneers, American Nursery, Leytonstone.

ST. ALBAN'S, HERTS.

UNRESERVED SALE OF NURSERY STOCK.

MESSRS. PROTHEROE AND MORRIS are instructed by the Executors of the Mortgagee (in consequence of the Estate having been disposed of), to submit to public competition, on the premises, the Key Field Nursery, St. Alban's, on Monday, Nov. 18th, 1844, and following days, at 11 o'clock, the whole of the varied NURSERY STOCK, comprising Fruit and Forest-trees, Evergreens, Ornamental, Deciduous, and American Plants of every variety, and about 3000 Standard and Dwarf Roses, consisting of the choicest varieties; 1,000,000 Quick and Oaks, of different ages; Seedling Beech, Ash, &c., Sea Kale, Asparagus, and Rhubarb, Dahlias, and Herbaceous Plants. The lots will be arranged to suit large and small purchasers. May be viewed one week prior to the Sale. Catalogues 6d. each, returnable to purchasers, may be had on the premises, of A. A. DORANT, Auctioneer and Land Surveyor, St. Alban's; of the principal Seedsmen in London, and of the Auctioneers, Leytonstone, Essex.

EXTENSIVE SALE OF A CHOICE COLLECTION OF EVERGREENS, AMERICAN PLANTS AND SHRUBS.

MR. MATTHEWS (of Spital Square) is instructed to Sell by Auction, on the Premises, Boddicot House, Homerton, on WEDNESDAY next, OCTOBER 30th, 1844, at 11, for 12 o'clock, on account of the number of Lots, A LARGE AND VALUABLE COLLECTION OF EVERGREENS, CHOICE AMERICAN PLANTS AND SHRUBS, in great variety; two very superior Greenhouses, 29 feet by 16, and 21 feet by 10, with Flower Stages. A great quantity of Iron Fencing, Forcing, and Melon Frames, several Summer Houses, Iron Garden Seats, and numerous out-door Articles. The complete erection of a most expensive BATH-HOUSE, fitted in an unusually convenient way, with Marble Plunging Bath (Cold or Tepid), Hip and Shower ditto, Dressing Rooms, &c.; the whole of which, with its numerous Pipes and Fittings, will form one valuable Lot (unless in the meantime disposed of by Private Contract), and being detached is capable of removal at a small expense. Also a small Stack of Meadow Hay.

May be viewed until the Sale, and Catalogues had of the Gardener, on the Premises, and (by post or otherwise) at Mr. MATTHEWS'S, Auction and Estate Offices, 2, Spital Square, Bishopsgate-street.

AMERICAN NURSERY, KING'S ROAD, CHELSEA.

To Noblemen, Gentlemen, Nurserymen, Florists, and Others.

MR. KIRKE will sell by Auction, on the Premises (late the American Nursery), King's-road, Chelsea, on WEDNESDAY, OCTOBER 30, 1844, and following day, at Eleven for Twelve o'clock (each day), by order of the Proprietor, the ground being required for other purposes, the VALUABLE COLLECTION, comprising several thousand Ansuba japonicas, Laurels, Laurestinus, Hollies, Box (common and Siberian), Lilacs, Roses, Portugal, fine standard Mulberries, Yews, a quantity of large ornamental Flowering Shrubs and Evergreens, Yuccas, Orange and Lemon-trees, Greenhouse Plants, &c. &c. (arranged in large and small lots, to suit the convenience of purchasers), and Greenhouses. May be viewed two days prior to the sale. Catalogues had on the premises; of Messrs. GAINES, Seedsmen, Covent Garden; Messrs. T. and C. LOCKHART, Seedsmen, Cheapside, City; and at the Offices of the Auctioneer, 29, Brompton-row, Brompton.

TO GENTLEMEN, NURSERYMEN, AND OTHERS.

LAVENDER-HILL NURSERY, WANDSWORTH-ROAD, NEAR LONDON.

During the month of November, will be sold by Auction, unless previously disposed of by private Contract, the valuable and healthy NURSERY STOCK of the late Mr. W. PAMPLIN, by order of the Executors, consisting of about Nine Acres of general NURSERY STOCK, particularly abounding in the Finest HARDY EVERGREENS, of all sizes; FRUIT-TREES, SHRUBS, and PLANTS; Large and Small CAMELLIAS, an extensive Collection of FERNS (some of extreme rarity); Erection of Greenhouse, Garden Frames, and Lights; Garden Implements, Shop Fixtures; quantity of Vegetable and Flower Seeds of the present Harvest, including a half-cwt. of best White Spanish Onion, Early Cauliflower, &c. &c.

Due notice of particulars will be given in a future advertisement. Meanwhile, parties contemplating purchasing the Leases of the Premises will be treated with at once, and may learn full particulars, and may inspect the Leases, on applying to Mr. W. J. LOAN, Clapham Common; or to Mr. W. PAMPLIN, Bookseller, 45, Frith-street, Soho.

HANTS.

TO BE LET, with immediate possession, a most desirable TITHE FREE FARM, containing about 62 Hundred statute Acres of Arable and Pasture Land, surrounded with good Markets. Also, a good WATER CORN MILL, adjoining the above Farm.

For particulars apply to WILLIAM FAWCUS, Esq., Manor House, Hayling, Havant, Hants.

NEW CATALOGUE OF FLORISTS' FLOWERS.

MESSRS. TYSO AND SON'S DESCRIPTIVE PRICED CATALOGUE of their extensive Collection of Tulips, Ranunculuses, Geraniums, Carnations, Picotees, Pinks, &c. &c., for 1844, is just printed, and will be sent, post free, to applicants inclosing two postage Labels.

Wallingford, Oct. 26, 1844.

BROMPTON-PARK NURSERY AND SEED ESTABLISHMENT.—ESTABLISHED 1681.

MESSRS. GRAY, ADAMS, AND HOGG have much pleasure in directing the attention of their numerous customers to their extensive NURSERY STOCK, consisting of Dwarf and Standard Maiden and Trained Fruit-trees, Figs, Vines, &c. &c., all of which are this season of a very superior description, and will fully maintain the reputation this establishment has for such a long period of years enjoyed for producing these articles. The peculiar nature of the soil renders the removal of all ornamental trees and shrubs almost certain, of which there is a select and extensive collection; together with everything that is desirable in the class of Greenhouse and Herbaceous Plants.

MARKET GARDENERS are invited to inspect a fine stock of Half Standard Apples, Pears, and Plums, which they will find well worthy their attention.

The SEEDS of this season that have come to hand are generally of a very fine quality, and of which Catalogues will be issued in due course.—Kensington-road, October, 1844.

The Gardeners' Chronicle.

SATURDAY, OCTOBER 26, 1844.

MEETINGS FOR THE TWO FOLLOWING WEEKS.

FRIDAY,	Nov. 1	Botanical	0 P.M.
TUESDAY,	Nov. 5	Horticultural	2 P.M.
		Linnean	8 P.M.
SATURDAY,	Nov. 9	Royal Botanic	4 P.M.

THE ACTION OF LIGHT AND MOISTURE UPON CUTTINGS is hardly inferior to that of heat. Let us glance at their action separately.

The moment light strikes a green plant it excites perspiration. Let us imagine that a cutting weighed 20 at daybreak; the uninterrupted action of light upon it during the day would perhaps reduce its weight to 5, unless it is supplied with water to replace that which the sunlight drives off: the effect of this would, of course, be to kill it. But such a result does not often happen to rooted plants, because they are able to suck fluid out of the earth as fast as the sun drives it off from their leaves, and the circulation of the plant is active enough to prevent any part from being exhausted of fluid. If it is not sufficiently active, then we have leaves withered at the end, or branches struck with dryness. But a cutting, having no roots, is unable to contend against the sun's influence, and therefore it must be shaded; for, as we cannot make it feed, we must prevent its wanting food. Thus in tropical countries we learn from Mr. Neumann that cuttings are struck in sheds shaded by straw and watered occasionally; with us the same point is also gained by cutting off the leaves, or a part of them, for they are the chief perspiring organs.

But there is this disadvantage in cutting off the access of light, that roots are formed more rapidly when cuttings are exposed to light than when they are shaded, provided they can be kept alive. It is therefore a great problem to determine how much light a cutting will endure with impunity. The power of bearing light varies from species to species, and is only to be determined by experience. One plant fades presently, because its powers of perspiration are very great, as is the case with the young shoots of most species of herbaceous and shrubby plants; but as they grow older the loss by perspiration diminishes, because their thickened skin opposes a mechanical obstacle, and they can bear more light. It would therefore seem, at first sight, that ripened cuttings must in all cases be preferable to those which are young and tender. Certainly, they are less liable to die quickly; but they are also much more unwilling to root quickly. In fact, notwithstanding the difficulty of keeping very young cuttings alive, they present the only means of striking very difficult species, such, according to Mr. Neumann, as the Cashew, the Mahogany, and the Litchi. We may lay it down as a certain rule that the power of rooting is always greatest in all cuttings when they are first pushing, provided they have light. The misfortune is, that they are so extremely perishable at that time.

Water is our aid in this case. It is true that the sun's influence can have no injurious tendency so long as the roots can drink and the system digest as fast as the surface perspires; and that the reverse is fatal. But the whole surface of a plant absorbs as well as evaporates, and the younger it is the more it absorbs. It is therefore possible to give plants drink by their leaves; and if this is done with skill, the bad influence of the sun is prevented. In that case the cutting has time enough to make roots, by which its grosser food may be conveyed to it. Hence has arisen the practice of striking plants under bell-glasses, fitting tight to the soil on which they rest. Ignorant people believe that the use of a bell-glass is to keep out air, which is impracticable and useless. Bell-glasses act by keeping in moisture. From the surface of warm damp soil water is perpetually escaping in the form of invisible vapour; if the soil is freely exposed, that vapour is dispersed as fast as it is formed; but when it is confined beneath a bell-glass the air is unchanged, and the vapour remains in a state of suspension, bathing and invigorating the whole surface of the cuttings. If this is well managed the whole of the injurious effects of sunlight are prevented, and all the advantages of it secured.

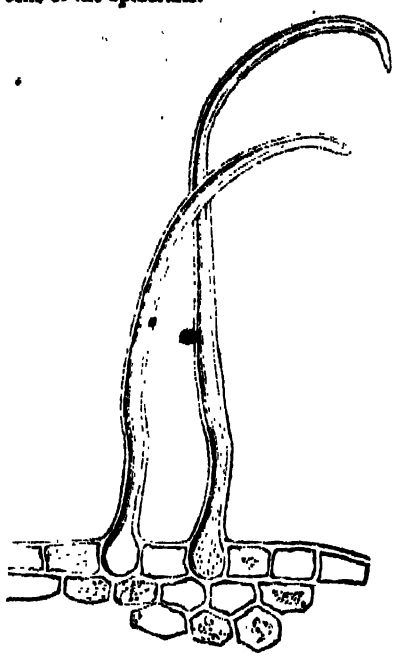
But it is not sufficient to place cuttings under a bell-glass with a moist soil and a due supply of bottom-heat. Two other things must be considered: the one is, to preserve the external air in a uniform state; the other is, to take care that the soil is not too wet.

If the air on the outside of the bell-glasses is not as warm as that beneath them, or warmer, the moisture floating in their interior will condense on the sides of the glass and run down, by which means the air that surrounds the cuttings will fluctuate as to the quantity of water it holds suspended; and if the external air is much colder than the internal, will, in fact, be dry, instead of damp. In their delicate state tender cuttings will not bear this; it is of the utmost consequence to them that all the conditions to which they are exposed, except light, should be perfectly steady.

The condition of the soil as to water, is also of infinite importance. If it is wet, cuttings are apt to rot. If dry, they are sure to fade. When a cutting is placed in a wet medium, it may attract more water than it can digest; in that case its fluids will become putrid, and its solid fabric must decay. It is therefore indispensable, in all delicate operations, that the soil should be of such a nature as to be incapable of holding much water between its particles; and hence the value of silver sand, the most favourable of all the materials within a gardener's reach. Nevertheless, there are some hard-wooded plants which will not only bear an excess of water but are the better for it. We have seen the common Ghent Azaleas struck by placing a cutting of the young wood, with a heel to it, in a bottle of water, inclosed within a large Ward's Case, none of the leaves having been removed. In such plants as the Azalea, however, it is to be observed, that the dense texture of the wood prevents the introduction of much water at a time, that the cuttings are very slender, and the leaves very large. Plants that are differently constituted can bear no such treatment. Let it be tried with a succulent plant, and the cutting would be rotten in a week. Succulent plants, indeed, will generally do best where there is no more moisture in contact with them than what the air holds suspended. When they are gummy, or milky, or resinous, it is necessary to let the end which is to be plunged in the ground become dry, so that the mouths of the veins may contract, and thus hinder the too rapid introduction of water. Mr. Neumann's mode of doing this is ingenious. When he takes off cuttings of Araucarias, Euphorbias, Vahea gummifera, and such plants, he plunges them in a pot, in damp earth, not pressed down, with their lower end upwards, so that the latter only is exposed to the air, the whole head being buried. By this means he dries the wound, without allowing any of the water of such cuttings to escape. After leaving them for 24 or 36 hours, or even more, he wipes the end, so as to remove the gummy matter that has exuded, and then puts them in again in the usual way, when they take, and the more freely according as the wound is neatly made.

One observation more and we have done for to-day. It is known that plants possess some quality analogous to animal irritability, to which, for want of a better, the name of excitability has been given. In proportion to the amount of excitability in a given plant is the power which its cuttings possess of striking. The great promoter of vegetable excitability is heat. Therefore the more heat a given plant has been exposed to, within certain limits, the more readily its cuttings will strike root. This explains what seems to have puzzled Mr. Neumann. "The young wood," he says, "of trees growing in the open air will not do for cuttings; and yet, if those same trees are forced in a hothouse, their cuttings are almost sure to succeed. Physiologists have not discovered the cause of this singular phenomenon. Many attempts have been made to strike cuttings from trees growing in the open air, but without success. If, for instance, we take an old branch of Pawlownia Imperialis, in the month of March, and put it into earth, or tan, or even water, in a stove with a good temperature, its buds will soon appear, and as soon as they are long enough to make herbaceous cuttings, will strike freely. But if you take them as they form upon a tree exposed to the open air, they will not grow at all." Vegetable excitability, a most important attribute, but little thought of, is the obvious explanation of this fact; with which, however, we were not previously acquainted.

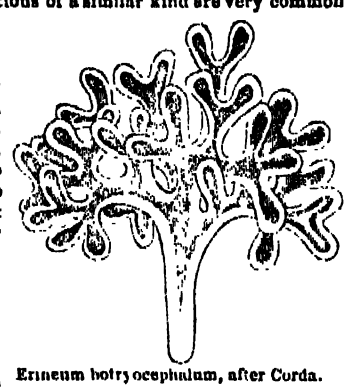
MILTONIA SPECTABILIS.



THE following is the way in which I cultivate this plant; and, in the first place, lest some people may imagine that the accommodation here for stove plants is large, and the mode of heating, &c., conducted on the newest and most approved principles, I may mention that all the convenience I have for growing specimen stove plants consists of a shelf which goes round the ends and front of a Pine stove; the whole length of this, including the ends, is 38 feet, and 2 feet in width. I have not, therefore, room for growing even Miltonia spectabilis to half the size that, with increased accommodation, I conceive might be very easily accomplished. This house is heated by common brick flues, with covers of the same material, each cover having a cavity an inch in depth, for holding water, with which they are generally filled three times a day, excepting in winter when the weather is foggy, or the frost severe, when I consider that a very humid atmosphere is injurious, especially to Orchidaceæ that are making young growths. In winter, when the weather is cold, the thermometer is allowed to fall to 55°, and in very mild weather it is allowed to rise as high as 70°; but from 60° to 65° may be stated as the general winter temperature. In summer the thermometer is allowed to vary from 65° to 80°, but from 70° to 75° is our ordinary summer temperature. In warm weather air is admitted freely by the top sashes; in cold weather it is very sparingly admitted, and when we have severe frosts, accompanied by high winds, I give no air unless the sun-heat is strong. In the selection of soil for Orchidaceous plants, as many of them are in their native localities found in shady forests, where decomposed leaves, incorporated with vegetable fibre, are likely to form the principal ingredients in which the terrestrial species naturally grow, I made choice of material from a wood where decomposed leaves are in some places to be found from 1 inch to 4 inches in depth, thickly covered with Luzula maxima, and completely matted with its roots. This material I use in a fresh and rough state, merely divesting it of the green stems of the Luzula, and pulling it into pieces suitable for filling up between the ball of the plant and the sides of the pot into which it is shifted. I always mix this material with a small quantity of coarse river sand, and sometimes a few pieces of rotten wood, to keep the whole as loose and open as possible, which I consider of great importance. In this compost there are few Orchidaceous plants which have come my way that do not thrive. I received a single pseudo-bulb of Miltonia spectabilis having two buds beginning to push, in the autumn of 1838. I potted it into a No. 60 pot, in the material above described, which I have uniformly used; in the spring of 1839 it perfected its young pseudo-bulbs, which, in their turn, immediately began to push, when I again shifted the plant into a larger pot; as the young shoots lengthened they showed a tendency to grow to one side of the pot. I pegged them round in the opposite direction, as far as I could venture, without straining them too much, in order that the plant might regularly cover the pot. This I have always punctually attended to, once, and sometimes twice a-year, as it was required; in that year (1839) it produced three flower-stems, which I valued more highly than I did the 46 it this year produced, 36 of which being the exact number in bloom when I exhibited it at Glasgow in August last (see p. 573). I cannot state accurately the different sizes of pots into which it has been progressively shifted, as in that respect I have been entirely guided by circumstances; but I am perfectly certain that I got it at the time, and in the state above described, that it was first put into a No. 60 pot, and that it has since been regularly shifted once a-year, sometimes in spring, and sometimes in autumn, according as the plant required it; for I consider it a matter of little moment at which of these seasons it is shifted; I am certain that in either case it grew equally luxuriantly; it has here always made fresh growth in spring, at which time I shifted it, and it has just as regularly made fresh growth in autumn after it has ceased flowering, at which time I shifted it when I adopted that season; but in both cases I allowed the young shoots to grow from 2 to 4 inches in length before I shifted, which enabled me to peg them down in the place I wished them to occupy. The pot in which the plant is at present growing is 16 inches in diameter. The plant is densely covered with healthy foliage and young growths; many of the latter are now protruding from 2 to 4 inches beyond the rim of the pot. I have not said anything respecting the drainage of the pots, as every one who knows anything of pot-culture must be aware that that is absolutely necessary for all plants, and more especially for Orchidaceæ. In summer I have always supplied Miltonia spectabilis freely with water when the soil appeared dry, and in winter I give no more than I consider necessary to keep the plant in a growing state, which ought to be always maintained. I consider shading from the direct rays of the sun to be of the utmost importance in the culture of this plant, so much so that for some years past, on the approach of hot weather in spring, I tack a piece of thin canvas or cheese-cloth over the place where it stands. I do not remove this until about the end of September, when the sun loses its scorching influence. From the want of proper attention to shading, I strongly suspect the majority of complaints regarding the yellow appearance of Miltonia is attributable to that. In conclusion, I think it but justice to say, that I could have had the plant considerably larger, having in the course of the time above stated taken eight young plants off it, the first of which was detached not more than 18 months after I received it.—*A. Turnbull, Bothwell Castle.*

DISEASES OF PLANTS.—No. V.

[FUNGI.]



WE have, before entering on the true Fungi, to dispose of a group of productions which have been arranged

by botanists under various genera as distinct species, but which are in reality nothing more than a diseased state of the cells of the epidermis.

Erineum Juglandis, to show how the threads arise from the cells of the leaf.

Every one must have remarked the swollen spots which occur so frequently on the leaves of Vines and Walnuts, and if they have had the curiosity to examine the under side of the leaf, they will have found in the one case a woolly mass, at first white and sparkling, but soon becoming brown; and in the other a short white velvety stratum. Productions of a similar kind are very common upon trees, especially of those belonging to the Natural Order Amentaceæ, such as the Birch, Beech, Oak, &c., though by no means confined to them. It is not uncommon for more than one form to be produced upon the same tree—a circumstance which has confirmed many in the notion that they are parasitical Fungi. They are found in all parts of the world, and exhibit in tropical climates many very curious forms far more highly developed and complicated than in our northern regions, where indeed they appear to be most abundant. In Northern America, a few kinds only are found, and those, with a single exception, European forms, and of rare occurrence. The Lime, which in Europe produces them so abundantly, in America has at present not been found to produce a single specimen.

Erineum botryocephalum, after Corda.

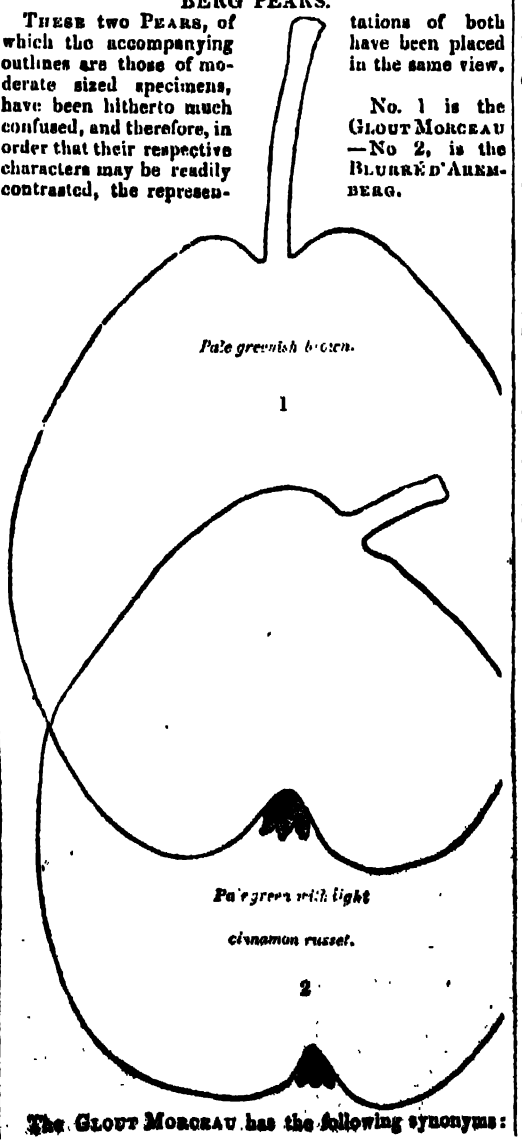
In form they vary from that of a simple or jointed thread, through every grade to a beautiful cluster, as in Erineum alneum and E. botryocephalum; or a complicated cellular mass, as in Septotrichum lamellosum.

In infancy they are usually white, though sometimes red or yellow; but they acquire as they grow old rich tints of red or brown—rarely of golden yellow. They occur in all soils and in all situations; and, as in so many other diseases of plants, the causes which favour their development are utterly unknown. If carefully examined, they are found to be continuous with the cells of the cuticle, and they contain a grumous mass of the same nature as that contained by the cells, but acquiring by degrees the tint peculiar to the particular form; on the copper-coloured Beech, the colour of the grumous mass partakes of the rich tint which distinguishes the matrix. That they arise from the cuticle in the same manner as the hairs, is now matter of doubt to few, though new species are still proposed; and within a short time magnificent illustrations have been given of these bodies by Corda, who, however, speaks doubtfully of their nature. A special work is also devoted to the subject, by Fée. They are not accompanied, except accidentally, by any insect, but appear to arise from an excess of nourishment, causing the cells in certain portions of the leaf to swell, and possibly the hairs themselves; and it is probable that they are in many cases beneficial to the plant, exactly in the same way as certain eruptions in the animal kingdom. It is, indeed, possible that when the disease exists to a very great extent, a portion of the sustenance intended for the young fruit is diverted; and I have observed that, in such cases, the leaves sometimes wither prematurely, which must be injurious to the next year's crop.

Septotrichum lamellosum, after Corda.

It has been a question whether the same situations which are favourable to the development of hairs on leaves are so to that of these eruptions. Such, however, does not appear to be the case; nor, supposing them to be mere anamorphoses of the hairs, does it appear to me to follow, as a matter of course, that it should be so. Nor, indeed, does it seem quite certain that they are always over-developed hairs, however analogous they may be to them, or however similar their origin. Some of the productions, indeed, which are referred by authors to Erineum are nothing more than patches of hairs in the axils of the nerves in their normal condition. Where one tree is affected by the disease, it is common for every tree in the neighbourhood to be similarly affected. They depend, therefore, upon certain conditions of soil and climate; and even were these known, it would perhaps be difficult to suggest a remedy; nor, indeed, if the effects be no more prejudicial than stated above, would it be of much importance to do so.

One or two productions of a somewhat different nature are also, without good grounds, referred to Fungi. The little pustular spots which occur upon the smooth bark of trees, as the Alder, and which contain a brown pulverulent mass of a mealy or branny appearance, are clearly nothing but a diseased state of the bark (Hypophlæa), which from some unknown cause is more or less perfectly resolved at these points into its constituent cells. I have seen something similar on a species of Bassia, from Burma, kindly communicated to me by Dr. Lindley, in which a portion of the cuticle and the subjacent cells split off in the form of a lid, leaving a cup behind; but, in this case, an insect may have been at work. A production not very dissimilar occurs on the common Laurel.



Perhaps, with as little reason, some of the bodies occasionally developed in the cells of plants, known, but at present imperfectly, under the name of Protomyces, are referred to the vegetable kingdom. I have not, however, had an opportunity of examining specimens; but in the genus Physoderma, illustrated by Corda, I am distinctly of opinion that the supposed reproductive bodies are mere diseases of the cells; as I believe the bodies in Protomyces to be a diseased state of the contained granules. Turpin was of opinion that such was the case in the important family of Mildew, Rust, &c. But that, in this case, he was wrong, has been amply proved by the researches of Léveillé and Corda.

In the ensuing Paper I shall say a few words on Galls, because, though caused by insects, they are often referred to Fungi; and there is a curious analogy in the forms which they assume, so that they occasionally deceive even practised eyes.—*M. J. Berkeley.*

GLOUT MORCEAU AND BEURRÉ D'AREMBERG PEARS.

These two Pears, of which the accompanying outlines are those of moderate sized specimens, have been hitherto much confused, and therefore, in order that their respective characters may be readily contrasted, the representations of both have been placed in the same view.

No. 1 is the Glout Morceau—No 2, is the Beurré d'Aremberg.

The Glout Morceau has the following synonyms: Gloux Morceaux, Goulu Morceau, Beurré d'Hardenpont, Hardenpont d'Hiver, Beurré d'Hiver Nouvelle, Beurré d'Aremberg (of some), Beurré de Cambron, Colmar d'Hiver, Linden d'Automne, Roi de Würtemberg, Got Luc de Cambron, Hardenpont's Winterbutterbirne, Kronprinz Ferdinand von Oestreich, Stück.

Frequent inquiries have been made respecting the meaning of the word *glout*, now generally adopted as part of the name of this Pear. Van Mons, "Arbres Fruitiers," p. 373, not then aware of the identity, describes the Beurré d'Hardenpont as scarcely distinguishable from the Glout Morceau. In quoting this, Dr. Diel incidentally remarks:—"This Frassbissen" (Glout Morceau) "is, however, unknown to me." Instead of this and similar meanings having reference to *gourmand*, the most appropriate explanation may probably be found in the sense in which the synonym, Goulu Morceau is occasionally employed: thus—*Pois goulu*, according to Chambaud, signifies sugar-peas, honey-peas; the Pear in question may be accordingly termed a sugared or honied morsel. This epithet corresponds with the quality of the fruit. Should a different meaning, however, attach to the word in Belgium, where the Pear in question and its name originated, information respecting such will probably be supplied through the kindness of some correspondent. The syn. Goulu Morceau was recently observed in the catalogue of M. Henrard, of Liege.

The Glout Morceau was raised by Councillor Hardenpont, at Mons. It varies much in its form; sometimes it is, on standards, roundish; but fairly grown on such, the accompanying outline affords a good representation. Occasionally, on walls, instead of obovate, it elongates considerably towards the eye, with an obtusely angular, or somewhat square appearance, and altogether not unlike the form of a Portugal Quince. The flesh is white, exceedingly smooth and buttery, rich and sugary, not the least acidity being detected in its flavour. The seeds appear more perfect than in most fine varieties, and this being the case, they deserve the attention of those engaged in raising seedlings. In some seasons and situations it becomes fit for use in November, in others not till January; but December is its most usual period. The fruit hangs late on the tree; and, in the southern counties at least, is best flavoured from standards. The tree is an abundant bearer, hardy, not disposed to canker. The shoots are dark olive, with prominent, diverging buds. Leaves ovate-oblong, crenated, or, near the extremity of the shoots, serrated, bright green; they may be distinguished by the wavy appearance of the margins. It ought to be in every collection; in various situations, in the open ground; on an espalier it succeeds well; and it highly deserves a south wall.

Beurré d'Aremberg.—*Synonyms:* Duc d'Aremberg, Deschamps, Colmar Deschamps, L'Orpheline, Beurré des Orphelines, D'Aremberg Parfait. It was raised by the Abbé Deschamps, in the garden of the Hospice des Orphelines, at Enghein. M. Noisette, of Paris, introduced to the French nurseries a variety of Pear from the garden of the Duc d'Aremberg, and which was in consequence extensively cultivated under the name of Beurré d'Aremberg; but this proved to be the Glout Morceau, and hence arose much of the confusion which prevailed with regard to these varieties. The fruit of the Beurré d'Aremberg may be distinguished from that of the Glout Morceau by its shorter stalk, generally bent almost at a right angle to the axis of the fruit; the eye is frequently destitute of any remains of the sepals or calyx. The flesh is melting and more juicy than that of Glout Morceau, but not so fine and buttery; and, except in very favourable seasons and situations, there is an acidity of which few approve, but some do prefer it as being refreshing. On this account it is not so well adapted for general cultivation as is the Glout Morceau. In a warm season and good situation its acidity becomes changed, and in that case it is, at maturity, a rich melting fruit. Its general period of ripening corresponds with that of the Glout Morceau. The tree bears very abundantly, so much so, that the fruit is often very small from standards. The wood is not entirely free from symptoms of canker. Shoots clear yellowish brown, sprinkled with small oblong pale brown specks. Leaves oblong, tapering to the apex, somewhat folded, and towards autumn the middle rib is much recurved in many instances. It must be allowed to rank as a first-rate Pear under favourable circumstances; but its merits, on the whole, are inferior to those of the Glout Morceau.—*R. T.*

Home Correspondence.

Pruning Forest Trees.—In last week's Paper, I saw an answer from Dr. Thackeray to some critical remarks of Mr. Billington's on the management of the Nerquis Plantations. Admitting that the trees in the Nerquis Plantations are fine specimens of growth, does it follow that their vigour is solely attributable to the pruning they have had? Certainly not. And in this I entirely agree with "Quercus." Dr. Thackeray's theory may be stated as follows:—1st. That timber is formed by the ascending sap. 2dly. That by pruning off side branches, the quantity of sap supplying those branches is forced into the stem, thereby increasing its bulk. He endeavours to support this assertion by referring to amputations of the human frame as a means of producing corpulency! But the comparison is erroneous, and utterly fails in showing an analogy between the vegetable and animal kingdoms. I can only repeat what has been previously stated in your columns, viz., that, other circumstances being alike, the vigour of a tree is in exact proportion to the amount of foliage exposed to

solar light, and consequently trees growing singly generally contain the greatest amount of timber; but, from the branches having the power of spreading in each direction unobstructed, the bole or trunk, which may be called the marketable part, is often out of proportion to the branches; and this can only be managed to advantage, by tolerably thick planting and judicious thinning afterwards. The branches being thus prevented from taking a strong lateral direction, the plants get slightly drawn, and a proper bole or trunk is formed. Take care to thin whenever their branches interfere with each other, keep a single leader, and prevent strong lateral shoots from forming, by pinching out their extreme points when growing, and whilst the trees are young, and there will be little occasion for using either the knife or saw. Trees will thus be formed with finer timber and of more value than those managed by the most refined dogmas of cutting and pruning that were ever laid before the public.—*John Spencer, Bowood.*——*Quercus* says—"The Articles in last Number, relating to Forest-tree Pruning—and the Nerquis Plantations, by Dr. Thackeray and Mr. Roberts—are both amusing and instructive; both attack Mr. Billington, and I fear with little advantage either to the respective combatants, or to the Nerquis or other plantations. If Mr. Billington conducted his inspection under the influence of prejudice, and an overweening partiality to what he calls his own system, and gave the public, through your columns, a warped and distorted description of Dr. T.'s plantations and the management of them, he is very much to blame; at the same time, Dr. Thackeray, in "accepting Mr. B.'s premises to overthrow his conclusions," is, according to my opinion, greatly beside the mark. He may be professionally correct in stating that the amputation of a limb from a patient increases the tendency to grow stouter—why? because the nourishing powers remain the same, while, minus a limb, there is less to nourish. The analogy will not hold; for, according to Mr. B., the plant is nourished by that of which Dr. T. deprives it. I agree with neither, yet partly with both; nor do I think Dr. T. happy in the instance he gives of a transplanted tree, to elucidate what I imagine is an erroneous notion, which he "conceives no one can deny—that the various branches Mr. B. would preserve, must appropriate to themselves a certain portion of sap which would otherwise go to the nourishment of the parent stem." In this quotation lies the radical mistake of the pruners—something of a piece with accelerated stoutness of a patient, otherwise healthy, when deprived of his leg. Mr. Roberts's letter goes to show that the ultra-Pontey system is that followed at Nerquis: it shows up Mr. Billington's prejudices, and says that his "system" is wrong; but these gentlemen may each in his turn show up the errors and mistakes of the other, without either being right. I would only beg each of them to study Nature and assist her operations when practicable, but not to violate her in accordance with their "systems," however fondly cherished."

Culture of Tulips.—The best aspect is south-east or south-west; the beds should be upon an open space, 8 yards at least from any wall, to avoid the reflection of the sun. The soil should be free from manure, rich, and rendered light by well-working it. It should be taken from the surface of a field where Corn or Colza has been grown. In August or September this earth should be carefully passed through a sieve. Dig out the beds 3 or 4 feet in depth, and in breadth about 3 feet 4 inches; the length will be determined by the number of plants. Take out all the earth from your beds, and replace it by that mentioned above. Where great attention is paid to the cultivation of Tulips, the beds are inclosed by a frame of wood 4 inches high in front, and 8 inches high behind, which serves to keep up the beds, and to form a plane slightly inclined to the sun. A good effect is obtained by two parallel beds, separated by a path a yard in width, having their surfaces inclined towards each other. Animal manure injures the Tulip; the remedy which has constantly succeeded with me is the "marc of Colza" * reduced to powder. I take out the earth from the surface of the beds about 7 inches in depth, and spread upon the remaining earth 35 lbs. or 40 lbs. of this marc, which I thoroughly mix, and then replace the earth which was taken out. When the bulbs come in contact with the marc, its fermentation favours vegetation, and contributes to the nourishment of the plant. 40 lbs. of marc suffice for a bed 12 yards long.—The above was sent to me by a French gentleman who has been very successful in Tulips. The mode he adopts with regard to the Colza, I imagine might suggest some useful hints. Perhaps some of your readers would be so good as to notice what might serve as a substitute. Would oilcake do?—*H. B. Mason, Brewood, Wolverhampton.* [No doubt.]

Whitney's Composition.—In spring I procured a bottle of this, and applied two coats of it to moderately-thick calico, strained over hoops, to use in place of a hand-glass: it has rendered the calico, after six months' use, so exceedingly brittle, that the least touch tears it; so that it is in effect useless.—*Philobotanicus.*

Planting Pines in Tan.—The following is a reply to "Judex," who seems disappointed at my not complying with certain statements in his communication at p. 524, and who again, in a still longer article, p. 684, insists that he has tried my system of planting in tan, and that it has proved a complete failure. I appeal to the readers of the *Chronicle* whether this is not injustice, as his compost is of his own invention, and quite in opposition to that recommended in my Treatise, pages 59 and 60, where I recommend nothing but pure British tan, on account of its undergoing a slower putrid fermentation than foreign tan; I state that as it decays it is rendered less fit for supplying plants with food, and that those which I had planted in old tan made very little progress. I have discovered this season, however, that old tan well watered with liquid manure is rendered sufficiently fertile for the culture of the Pine. "Judex," in the commencement of his first article, writes as follows:—"Acting under the advice given in Mr. Hamilton's 'Treatise on the Pine-apple,' I planted out, a few days after his work appeared, 24 fruiting plants in tan, or rather tan and decomposed leaves, just what Mr. H. would have selected himself, being tan and leaves that had been at work about six weeks, and just in a decomposing state, mixed with about one-fourth new tan, just to give life to the mass." Now in my Treatise I recommend tan that will be long in decomposing. "Judex" puts his materials in a heap in order to hasten decomposition, and then adds one-fourth new tan to give it life, and states that such a material was just such as Mr. H. would have recommended; he thus misquotes my Treatise, in order to detract from its merits. Had "Judex" said that he had used pure British tan, as my Treatise recommends, and that it proved a failure, I would have attributed the failure to bad management, and not to the merely mixing fresh tan with decomposing matter, although this sours the whole mass. My book nowhere recommends such a compost, and all I want in favour of my system is an open field and fair play; and if I am to discuss its merits, let it be with one who is neither ashamed of his name nor of his residence. I am sure that I have recommended nothing in my Treatise but what has been well tested by long practice. Before I speak of tan, however, first let it be observed that all the results of my threefold advantage system of Pine culture are from plants which had been grown in soil, &c.; and that I merely, in the beginning of my system, recommended tan for trial. I have since tried it, and the result has more than surpassed my expectations. When "Judex's" first article appeared, I invited him to pay a visit to Thornfield, in order to see the largest fruit he ever saw, according to the size of the plant, growing in tan; but possibly he may have been one of the 109 gardeners that have visited Thornfield this summer, as nearly all of them were personal strangers to me, but all of whom signified their approbation of my system, and also bore witness to the fact that equal results were accomplished by plants growing in various composts. The same results may yet be seen; some of the plants are in pots, others are turned out in tan, &c. I, nevertheless, again invite "Judex" to visit Thornfield, and I imagine that he will see the largest Montserrat and Sierra Leone he ever saw; one is ripening, the other is swelling; both were planted in such tan as this locality affords, and let it be remembered that both plants are suckers; the Montserrat is maturing the fifth fruit in four years, from the same plant. I have also now ripening a fruit of the Black Jamaica of tolerable size, notwithstanding that it is the fourth fruit in three years. It is grown in a pot; its predecessor was cut in last December, and weighed 6 lbs. I have stated in my book that I had grown the Montserrat upwards of 7 lbs.; the Black Jamaica generally rather larger, and Enville 8 lbs. 14 oz., all in pots. Now, with these facts before me, and surely "facts are stubborn things," I may state that my system does not at all depend on what kind of material the plants are grown in, provided it is sweet when applied, and kept porous and uniform in regard to warmth and moisture. If the roots are sufficiently supplied with these, I have no doubt but that the Pine would grow suspended from the roof of a Pine-stove. Thus, it will be understood that my system of Pine culture comprehends something more than a mere course of routine management. Perhaps I was the first who completely exposed the absurd practice of disrooting the Pine. I have explained in my Treatise the real habits of the plant, the longevity and multiplying tendency of its roots, which forms the basis of my mode of culture, the results of which prove its superiority over the old system. I contend that the roots are co-existent with the plant; that the first roots formed at the base of the trunk are capable of being preserved so long as the trunk is ensured from the baneful effects of over-heats and sudden changes in the sub-temperature; and the equally bad effects of sub-acids, generally occasioned by using rich soils of not sufficient porosity to admit the influence of the atmosphere, they become soured. I therefore recommend the use of such composts as are capable of maintaining the greatest uniformity of heat, air, and moisture, as being best adapted for preserving the bottom of the trunk and roots in an active, healthy state, which is of the greatest importance to my present system of culture, as the roots are intended to remain for years undisturbed, that the plants may perfect a succession of fruit. Now, as I have stated in my Treatise, that sometimes tan is impregnated with something pernicious to the roots of the Pine, I would advise a trial of the compost given at p. 59 of my book, which I have used with the very best success. In order to further show the fertilising properties of tan, I may state a few particulars, namely, when Vines are planted in a corner of a bark-bed, partitioned off by bricks, to cause the roots to descend along the bottom of the tan in the bed, they grow most vigorously, and produce the most luxuriant shoots imaginable, in nothing but tan; and the number of bunches, and size of berries, are not surpassed by those grown in the richest composts; indeed, I have never tried any plant in tan but I have always found it to luxuriate more than in any other material. I planted a Musa Cavendishii, only about two feet in height, last March, in a corner of the tan-bed; it is now ripening about 70 fine fruit; its growth has been so rapid that all who have seen it are aware that it could not have been surpassed by planting in any other compost. I may state the same of an Ipomœa in the other corner of the tan-bed, which was planted out about six years ago. Again, so much has planting Pines in tan been a favourite in this locality, that the late Mr. Fallows, of Cotten Gate, near Didbury, succeeded so well with it, that he sold his receipt for 5*l.*, about 25 years ago, to several gardeners: one of them has fruited all his plants in tan ever since, and this season I am informed the plants are very fine. "Judex" will find that J. Justice, who published a work on Pines in 1740, (see p. 15 of my Treatise,) practised planting them in tan: he states, "the fruit were larger than those in pots, but not better flavoured." I have sent a specimen of Black Jamaica for the Editor's opinion of its flavour.—*J. Hamilton.* [It was of the best quality, and a most beautiful specimen of Pine-growing.]

Beehive Raspberry.—This has been cultivated in this neighbourhood for some years. I consider it identical with the one advertised by Messrs. Youell and Co., called the Fastolff. In good rich soils it continues bearing until it is destroyed by frost.—*John Spencer.*

Polmaise Heating.—I stated, at page 525 of the *Chronicle*, respecting this mode of heating, that the flue containing the heated air is situated at the back of the house, and that cold air is admitted from without, to keep up a healthy atmosphere; I also, at the same time, pointed out my reasons why such an arrangement would be fatal to any system. No answer has been attempted in explanation of these objections, unless it be the marvellous fact that Grapes were positively cut from this vinery, and exhibited in Edinburgh on the 20th of September! Why, anybody can do that without any heating apparatus at all. Nothing could have been more apposite than to place this system under the protection of him whose researches in Don Quixote had led him to believe that he had discovered the whole art of gardening. It is really quite terrible when he brings his small wit, and his smaller erudition, to bear on any subject relating to gardening. I repeat that, unless something like an explanation is advanced respecting my objections to this system of heating, I shall consider it useless to revert to it again. My only object has been to elicit the merits of the system, if it has any, of which I then was and still am doubtful.—*R. Glendinning.*——*H.* says—"The great results which have attended the system of heating at Polmaise appear to suggest an important consideration, to which, as far as I am aware, no one has yet alluded: it is this—Whether the method now so generally in use of employing hot-water pipes laid within the house, is really that perfect system it has hitherto been considered to be. The advantages of the Polmaise plan appear to consist chiefly in the introduction of fresh air previously warmed; and there can be little doubt that this method, affording, as it does, a free supply of oxygen for the healthful growth of the plants, approaches most nearly to the natural condition of the Vine in those countries where it attains the greatest perfection. There is a strong prepossession, however, in favour of hot water, and every one who has been accustomed to its use will be slow to adopt any other mode of heating; indeed, any return to the now almost obsolete hot air plans appears a step in a retrograde direction. But then, the nature of the pipe plan almost precludes the possibility of combining with it a supply of fresh warm air; to obtain this *desideratum*, therefore, and at the same time not to forego the advantages of hot water, recourse must be had to some of those modifications of the pipe system in which the air is heated before it enters the place where the temperature is to be raised. If any one has tried this plan, will they state with what result?"

Mr. Hoare's Vine Border.—Mr. Hoare, in his recent Treatise on Vine Borders, has especially drawn our attention to this important point more than any other writer on the same subject, and on that account deserves our thanks. Perfect drainage, and the exclusion of long continued rains, has been well understood by our best practical gardeners; but I think the exclusion of soil entirely from forming any part of the material necessary in the formation of a compost for the roots is a new doctrine, and an assumption opposed to our knowledge of horticulture, both practically and theoretically. The Vine may like to ramble amongst stones, lime rubbish, and such like, but our experience of the nature and habits of this plant is, that it delights in rich pasture, especially when subjected to the artificial treatment and temperature it usually undergoes, to produce such magnificent fruit as we annually see exhibited at the *fêtes* in the garden of the Horticultural Society. Soil intermixed with a portion of manure, will be more likely to attain the result just stated, than the absence of both. This may be considered mere prejudice; theory is all very well, but good practice with me has the preference. It is a question of some importance, and worth ascertaining, whether Mr. Hoare ever has produced by his system of prepared borders, Grapes superior, or even equal to those we witness every year at Chiswick, and which we know are the result of the old repudiated manured borders: for, after all, this is the question. Mr. Hoare is surely aware that the Grapes produced in this country in our vineries are not only equal, but, in the great proportion of instances, superior to those grown in the latitudes where the Vine is extensively cultivated, to which Mr. H. so often refers. I shall say nothing respecting Mr. H.'s recommendation of paving the border with brick or tile; we old-fashioned gardeners like to keep stirring the soil.—*R. G.*——In the Editorial remarks on Mr.

* Colza is a kind of Rape grown near Caen, in Normandy, from which oil is made. What is meant by the marc, is the residue after the oil has been expressed.

Hoare's Calumnar Vine Border, you have not expressed any opinion on the effect 32 of 14 degrees of frost, which in of common occurrence, would kill on the roots exposed on every side to its chilling effects. I should imagine this would at once prove a settler. — *John Spencer.*

Extensive Robbery of Auriculas.—The premises of Mr. Middleton, of Prestwich, near Manchester, were entered on the evening of Tuesday, the 15th inst or early the following morning, and the whole of his valuable collection of blooming plants were stolen therefrom. From inquiries which were subsequently made, suspicion fell upon a person of the name of John Scholes, who is a dealer in Auriculas, Carnations, Pinks, Polyanthuses, &c., and who resides at a place called Tongue-lane, near Middleton. Under these circumstances, a party was deputed to call upon him for the purpose of inspecting his plants, and, from what he observed, no doubt was entertained that the guilty party had been discovered. Information was forthwith given to the police, and, accompanied by Mr. Middleton, Scholes's garden was searched, and a number of plants were identified. He was immediately taken into custody, and on Friday, the 17th inst, was charged before the magistrates with the robbery. He expressed his surprise and indignation at the charge, and he alleged that many of the plants had been in his possession five or six years. The prisoner was remanded, and afterwards liberated on bail. On the same day his dwelling-house was searched, when the whole of the plants (with the exception of about a score, amongst which was a Freedom, a Ne plus Ultra, and a Colonel, remarkable in consequence of a leaf being cut across, which could not be removed without injury) were discovered under his bed, and the missing plants were admitted by him to have been sent away the Wednesday previous. The prisoner was again brought before the magistrates on the 22d, when, being asked what he had to say, replied, "I am Guilty." The magistrates consulted, and the prisoner was ordered to pay 5*l* 11*s* 6*d*, with a penalty of 5*l*, and in default thereof to be imprisoned 3 months. The accuracy of the above account is vouched for by Mr Watkinson, Seedsman, Manchester; Mr. Lodge, Nurseryman, Broughton; Mr. Slater, Florist, Cheetham-hill —— I think it right to call your attention to this case for these reasons:—First, that the delinquent should be exposed to the fullest extent; and secondly, that the attention of the public should be drawn to the state of the law with reference to such cases. If a poor person, to satisfy the cravings of nature, steal so much as a piece of bread, he is at once seized, and presently imprisoned for a considerable period; but should a party, as in the present case, steal property to a considerable amount, in plants, the law says such a party is not guilty of a felony, and is only liable to pay the value of the stolen plants, with a penalty not exceeding 20*l*., or, in default, to be imprisoned for a period not exceeding six months. It certainly appears to me extraordinary that such a state of things should be permitted to exist; and I, with other floricultural friends in this town and neighbourhood, deem it our duty to lay these facts before you, trusting that they will elicit such remarks as the justice of the case requires.—*Manamencis.*

Miscellaneous.—*Nemo* asks, in last week's *Chronicle* how to rid his aviary of mice. The only plan I find to answer here is, when I find them troublesome, to take up all the food of a night, and set traps; those set with thread, and baited with toasted cheese, or such as canaries are fed with, are the most suitable. The trap consists of holes, with a spring wire, which catches the mouse by the neck when he has gnawed the thread through. A cat would declare war against the birds.—*P. Frost* —— *Calceolarias* —I have observed that my friends mention the difficulty of striking Calceolaria viscosissima If they would put in their cuttings now, in cutting pots of sand, plunged in a very gentle bottom-heat, kept well shaded in sunny weather, and close during the day, but give a little air every morning to dry off damp, they would find there is no plant more easily propagated Indeed, I never put in cuttings of Calceolarias of any kind till October, and never fail.—*P. Frost.*

Cabul Melon-seed.—In your Paper of the 19th October we have noticed a note from Mr. Blomin, in which we understood him to assert that he has never parted with any of his Indian Melon-seed to nurserymen On reference to advertisement of ours you may perceive that we have effected a sale of the Mountain Melon warranted true from the fruits exhibited by Mr B As his letter will appear to our friends to give the lie to our assertion that the seed was true from his fruit, we must beg you to allow us to contradict him, and to remind him that very shortly after he had shown his fruits, we wrote to him, offering to purchase any seed he might have no use for, to which he replied, that he would not sell any, but that we might have it in exchange for some valuable plants which we had in our possession, we immediately sent the plants, and shortly after received the seeds which we afterwards advertised.—*R. White and Co.*

Societies.

MEETING OF THE BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

THIS Meeting, which was held this year at York, with more than usually numerous, and its proceedings in many of the Sections, were of a highly interesting character. For all that was generally important, we refer to other parts of our columns, and confine ourselves here to the botanical department. However much it may be lamented, the interest and value of the Botanical Papers in the Association have been gradually falling off, and there were, we believe, fewer botanists, and a smaller number of botanical Papers, than on the previous occasion. The causes of this is very obvious—botanists are not geologists, nor zoologists, nor chemists—and the mixing up zoology and botany in one Section has at last ended in the almost entire exclusion of botany from the consideration of the Association. A day was, however, set aside for the discussion of Botanical Papers alone, and we have been enabled to obtain simple abstracts of the most interesting of them. The following Papers were read by the Secretary, Dr. LANKESTER, from Chevalier SCHOMBURGK:—

"*Alexandra Imperatrices.*—This tree, one of the most gorgeous and beautiful of the extensive tribe of Papilionaceæ, was discovered by the author of this Paper at the foot of the southern ridge of sandstone mountains, in the fluvial basin of the river Cayuni, in Guiana, and reaches a height of from 140 to 320 feet. The flowers appear directly from the woody branches in large clusters; the racemes, pedicels, and calyxes, are of a rich crimson, the petals bright orange, striped with crimson; the vexillum of a deep purple, and ascending; the pod, which is from 18 to 20 inches long, is of a velvety brown outside, and contains several seeds of a chestnut colour.

"*A New Barbacenia* —Few regions in Guiana offer to the botanist such a rich harvest as the table land from which Mount Roraima rises to a height of more than 7000 feet above the sea, the last 1500 feet presenting perpendicular walls, formed of sandstone In these regions, under the 5th parallel of north latitude, and about 4000 feet above the level of the sea I discovered the plant which is the subject of this Paper, and which surpasses any other of that interesting group—the Velloziæ—hitherto described in size and beauty It reaches frequently a height of 10 to 12 feet, branching out in a dichotomous manner, and bears a number of flowers which in their appearance are liliaceous, and 5 to 6 inches long, the slender tube, covered with callosities, has a purplish tint; the perigon is inside snow white, on the outside, however, a delicate purplish tint spreads from the middle towards the margin The fragrance of these flowers is delightful, and the plants which produce them extend in groups for several hundred yards

'*Barbacenia Alexandrinæ* —This plant, with precisely the habit of some of the frutescent Velloziæ, has the perigonial leaves united into a tube above the ovary, as in Barbacenia It differs from the species of that genus hitherto described in the number of stamens, which are 18, all fertile; whilst, in the Brazilian Barbacenias the two lateral stamens of each bunch are sterile, and usually described as branches of the filament These differences in the number of stamens are not, however, admitted to be generic in the closely allied genus Vellosia and are therefore insufficient to distinguish generically a solitary species of Barbacenia and should be considered, therefore, merely a good sectional character. I have dedicated this new species to the Empress of Russia, the sister of my Sovereign

'*Calycophyllum Stanleyanum* —How splendid our Rose bushes under the temperate zone! That favourite plant alike cultivated by the rich and the poor, how they ornament the garden and adorn the hedges surrounding our fields, when in full blossom! Let, then, imagination convey you to the great garden of Nature in Guiana, clothed in tropical exuberance, and among those productions of a congenial sun and fertile soil, imagine trees from 40 to 50 feet high presenting a mass of leaves of the colour of our favourite flower, from a deep pink to the lightest rose, and imagination may assist to give a picture of the Calycophyllum Stanleyanum There are several genera of the natural family of Rubiaceæ, as Calycophyllum, Mussænda, Pinckneya, &c where one of the teeth of the calyx expands in a petioled coloured leaf of a membranaceous texture In the tree under description, this is the case in such a remarkable way that these bract like organs of different shades of rose colour are so numerous as to cover entirely the green leaves, and give the whole landscape a peculiar aspect, which appears *coelum de rare* It [illegible] only forms itself after the flower has dropped off, and grows with astonishing rapidity I discovered this beautiful tree on the banks of the rivers Rupununi and Pakatu, in the 2d parallel of north latitude, and I have dedicated it to Lord Stanley Secretary of State for the Colonies

"*The Snake Nut* —In a Paper communicated to the Linnean Society, and read the 6th June, 1837, and since printed in the "Annals of Natural History" vol v p 201 I attracted the attention of Naturalists to a curious fruit, a Drupe, the kernel of which, when opened, and the membrane which covered it being removed, displayed the striking resemblance of a snake coiled up I was not able to procure the blossoms of the tree which produces this strange fruit in such an advanced state as to permit me to describe it with accuracy and considered it at that time as belonging to the order Terebinthaceæ Shortly before my departure from Guiana, some perfect flowers were sent to me, which rendered it evident that the tree belonged to the natural order of Sapindaceæ, and with the assistance of Mr Bentham, I have described this curious tree as Ophiocaryon paradoxum The specific name relates more to the remarkable resemblance of the embryo to a snake, than to its deviation from the general structure of the tribe, which, in the section Dodonæeæ, presents us already with a spiral and twisted embryo

"*Lophira Lanceolata* —Bytteriaceæ are very abundant in Guiana and during our late expeditions in the interior, we met whole forests of one representative of that family, which no doubt belongs to the most useful and interesting, namely, the Cocoa or Chocolate tree Among the Bytteriaceæ which have been added as new discoveries to the list of genera and species of that family during my exploring tours in Guiana, is a plant of high interest, which I have named, after the Governor of British Guiana, Henry Light, Esq., 'Lightia" His Excellency took the liveliest interest in our exploring expeditions, and it is but a poor token of the gratitude I feel for his interest, if I name one of the new genera, discovered during that period, after him The specific name I have derived from *lanuscus*, a coloured ribbon hanging down on garlands or crowns, to which the cluster of flowers with its ribbon like appendages may be compared As the regulations of the British Association do not permit a full description of this interesting plant, I shall merely allude here to some peculiarities which this new genus possesses. It is true that the essential character of the order Bytteriaceæ as described by Lindley, and Endlicher, mentions already, that the petals are variously lengthened at the apex However, no other instance is known, as far as I am acquainted with it, in Flora's kingdom, where the elongation of all the petals is so considerable as in Lightia lanuscata, suspending like ribbons from the cluster of flowers. The tree, about 20 to 24 feet in height, has much the appearance of a Cecropia, and possesses, like Theobroma and some other genera, the peculiarity of producing its flowers immediately from the stem, below the axils of fallen off leaves. I have only found three specimens of this interesting plant; namely, the first, while traversing the mountains of the Upper Essequibo, in latitude 2° north; the second, near the river Barima, in latitude 8° north; the third, at the foot of the sandstone mountain of Roraima, in the valley of the basin of the river Cayuni

"*Two New Lauraceæ* —This Paper makes us acquainted with two interesting trees, of which, however, only the trivial name has been known. The first is a tree which the Macushies name of the most valuable timber which has been imported into England under the name of [illegible] Rodie discovered that the bark and the fruit of [illegible] tained astringent virtues, and though [illegible] mentioned by Wydenaar, in his "Natural [illegible] in Guiana, it is not now that its botanical [illegible] ascertained. It appears to be [illegible] genus [illegible] author has given to [illegible] Bentham, [illegible] under the European [illegible] of the Antilles

[illegible] Dr. Hancock published a highly interesting account of the Sloanea, a vegetable alkaline body, which he extracted from this tree, in the "Transactions of the Royal Society of Edinburgh," vol, xv. p. 213, (to which the author refers those interested in such matters); but he begs to observe, that if it be true that the Republic of Paris has laid restrictions on the importation of the true Cinchonas, this true deserves every attention—the more since it is to be found in such abundance at the coast region of Guiana. The second tree is of equal interest and, like the former, already described by Bancroft and Hartstonk The fruit was considered by the late Dr. Hancock as one of the most efficacious remedies in diarrhœa, dysentery, colic, and spasmodic pains. It has long been known under the name of the Arawaal Nhutang in the colony, and extensively used as a family remedy in the above diseases, but it is only now that the author has succeeded in procuring specimens of flowers and seeds, which pronounce the tree to be a new species of Aeroidichdium, to which he has given the specific name Camara, by which it is known to the aborigines where it grows It appears to be restricted to the sandstone mountains of Roraima, between the 5th and 6th parallel of north latitude"

On the Papers being finished, Professor BALFOUR, of Glasgow, stated that the wood of the Greenheart was used for building vessels on the Clyde. He had heard of the chemical preparation bibirine, obtained by Dr. D. Maclagan, but feared it was not so eligible a preparation as quinine. — Professor FILLEY, recounted the steps of the chemical process by which Dr. Maclagan obtained bibirine, as well as another alkaloid, from the wood and bark of the Greenheart. Dr. Maclagan had, however, since ascertained that there was but one alkaloid, although he had originally described two, the one being merely a form of the other. The bibirine was not in combination with an organic acid; it had an atomic composition, very closely allied to quinine. Dr. Lankester pointed out the necessity of the alkaloids for animal existence. Large quantities of theine and caffeine were daily consumed by man, and these alkaloids very closely resembled quinine and this new salt bibirine, in their composition.

Mr. BABINGTON exhibited to the Section specimens of three plants, which had been added to the list of British Plants during the summer of 1844.

1 *Alsine stricta* discovered on Widdy bank Fell, in Teesdale, Durham, by Mr James Backhouse, of York, and a small party of botanists It occurred in small quantity, but from the nature of the locality, and the plant inhabiting the northern parts of Europe, it must be considered as an aboriginal native of England.

2 *Carduus setosus*, growing near the shore of the Frith of Forth, in the neighbourhood of Culross. As it is a native of the countries to the north-west of the Black Sea, there is every reason to believe that it has been introduced from that region to Scotland by accident It has now taken firm hold in that place, where it was detected by Dr Dewar, of Dunfermline

3 *Galium ballantii* —This plant has often, and, perhaps, justly, been considered as a variety of the common *G Aparine* It has occurred to Mr G. S. Gibson, of Saffron Walden, Essex, in cultivated fields near to that town

After the reading of Mr. Babington's notice, Mr. O. A. MOORE read a report on the Flora of Yorkshire, written at the request of the Council of the Yorkshire Philosophical Society, and the drawing up of which was intrusted to himself and Mr. Baines, the well known author of the "Flora of Yorkshire."

He commenced by expressing his regret that owing to the shortness of the time allowed for its completion, it might appear not quite so perfect, in some respects, as it otherwise might have been, especially as regards species peculiar to the sea-coasts All plants, too, were excluded from the list not strictly found on the Yorkshire side of the Tees in Teesdale In this list were included 1117 species, and 138 varieties (many of which latter are considered species by some botanists), exclusive of a few whose claims to be regarded as Yorkshire plants rest on insufficient grounds The list might be regarded as an appendix to the work of Mr Baines, which appeared four years previously, and which contains an accurate and extensive list of habitats for all the principal flowering plants and Ferns of Yorkshire, as well as the Mosses and Characeæ In the present report the subsequent labours of botanists had been noticed, and about 87 species and 81 varieties were mentioned, which had not previously appeared in any general list. Additional localities were given for some of the rarer species, when only two or three had been previously recorded, and those botanists were mentioned through whose assistance much valuable information on the flowering plants and Ferns of Yorkshire was obtained, to which two families the list was confined. They were distributed into the following classes —*Exogens* species 806, varieties 103; *Endogens* species 262, varieties 35; *Acrogens* species 49, varieties 21. To this was appended an analysis of the species and varieties in natural orders. The list, which was of considerable length, was then gone through in a cursory manner, the time only permitting the leading points to be alluded to, and remarks were made on such species as were either very rare or had some peculiarity in their habit or mode of growth. The following were a few of the principal additions mentioned in the list —*Anemone apennina*, *Barbarea stricta*; this species was shown to be common in many parts of the county, especially on the banks of the Don, at Doncaster, at York, Sneaton, &c. Its claims to be regarded a distinct species were also pointed out. *Campilea dentata*, *Alyssum calycinum*, *Lepidium Smithii*, *Dianthus plumarius*, *Dianthus deltoides* var. *glaucus*, *Silene anglica*, *Hypericum perforatum* β. *Hypericum maculatum*, *Viola Orubus*, *Alchemilla alpina*, *Rosa involuta*, *Epilobium virgatum*, *Callitriche platycarpa*, *C. pedunculata* β, *Sedum reposatre*, *Saxifraga geum*, *Asperula arvensis*, *Valerianella auricula*, *Solidago virgaurea* β, *Artemisia campestris*, *Crepis succisæfolia*, *Hieracium diaphanum* α, *H Leyeyrouti*, *H. prenanthoides*, *H. rigidum* α, β, *H bifidum*, *Cuscuta trifolii*, *Orobanche rubra*. This plant was found at Leyburn Shaw, by Mr. Fullelove, and is another instance of the species not being confined to the basalt. *Scrophularia Ehrharti*, *Melampyrum pratense* β, *Veronica triphyllos*, γ, *Buxbaumii*, *Mimulus luteus*, *Mentha aquatica* β *silvestris*, *M. pulegium*, *Stachys palustris* var. β *ambigua*, *Primula farinosa* var. *pumila*. A curious dwarf variety of this plant, from Hawkswell Moor, was exhibited. *Chenopodium olidum*, *C. hybridum*, *C. murale*, *Atriplex littoralis*, *A. patula*, *A. deltoidea*, *Rumex maritimus* var. *paludosus*, *R. palustris*, *R. pratensis*, *R. acutus*; this plant was shown to be the common roadside sheet, at Masons Wensleydale, and grew on dry stony ground, &c. *Polygonum mite*, *Salix rubra*, *S. [illegible]*, *Potamogeton [illegible]*, *P. [illegible]*, *P. [illegible]*, *P. [illegible]*, *Alisma [illegible]*, *Triglochin palustre*, *Orchis [illegible]*, *O. [illegible]*, *Habenaria [illegible]*, *Iris [illegible]*, *Juncus [illegible]*, *J. [illegible]*, *J. [illegible]*, *Luzula [illegible]*, *Eriophorum [illegible]*, *Carex [illegible]*, *C. [illegible]*, *C. [illegible]*, *C.

[illegible] great number of copies of the "Flora Metropolitana" on hand. Such works ought to be known [illegible] as they are of great importance to the botany of a district. He then made some remarks on the rare plants referred to by Mr. Moore, and agreed with him in condemning many of the alterations made in the names of plants published in the Catalogue of a Botanical Society in London.—Professor BABINGTON also pointed out several errors in the list referred to. He stated, with regard to the Orobanches rubra, that he knew that it grew upon the grey wacke, and it could not now be regarded as a plant peculiar to basaltic formations. It was parasitic on the roots of Thymus serpyllum.

(*To be continued next week.*)

REGENT'S PARK GARDENERS' SOCIETY.

THE further discussion of Morphology at the open meetings in the rooms of this Society took place on the evening of the 23d inst. The meeting was very fully attended. Mr. T. Moore moved, as an amendment to the original resolution (which was in opposition to Morphology, as propounded in Dr. Lindley's "Outlines of Botany"),—"That the objections urged against the doctrines of Morphology are neither scientific nor satisfactory, and consequently the principles it maintains are entitled to the further and candid investigation of all those who are desirous of increasing their knowledge of the structure and functions of plants." Mr. Cale seconded the amendment. The meeting was also addressed at some length by Messrs. Sherwood, Maher, Ayres, and C. Moore, in favour of the amendment; and by Messrs. Reid, Fitzpatrick, &c. in support of the resolution. On a division, the amendment was negatived by 18 to 15, about the same number remaining neutral. The resolution was afterwards carried by a small majority.—*M.*

[We are not surprised at this result: the ignorance of the opponents of Morphology has been all along so enormous, that it is impossible to reason with them. They are incapable of comprehending an argument; besides, wiseacres always outnumber men of sense.]

COUNTRY SHOWS.

North Devon Horticultural Society, Sept. 18.—This was the Autumnal Meeting. From the garden of C. Roberts, Esq., was a great variety of plants; among which were—Crinum amabile, Achimenes pedunculata, A. grandiflora, Hibiscus Cameronii, Epacris variabilis, Fuchsia exoniensis, Rondeletia speciosa, Begonia floribunda, Cattleya Forbesii, and Russelia juncea. A fine Ixora bandhuca was exhibited, from Castle-hill. Mrs. Col. Mason sent Brugmansia sanguinea. A specimen of Renanthera coccinea was shown, from the garden of E. Roberts, Esq. Several Prizes were awarded, but we have only been furnished with a list of awards without the names of the flowers for which they were given.

Rebiews.

Lectures to Farmers on Agricultural Chemistry. By Alexander Petzholdt. 8vo. Taylor & Walton. pp. 300.

AMONG the crowd of books which the present demand for information upon the Chemistry of Farming has brought forth this may be recommended as one entitled to attention. The author does not overload his subject with needless details, which is the vice of some such books, but he confines the reader to those points only which he ought to be well acquainted with, and these he explains in a clear and simple way. He has also selected his experiments judiciously, so that a person who desires to master the elements of the subject may do so without assistance, if he can command a small supply of common agents and unexpensive apparatus.

The author's clear way of treating chemistry may be collected from the following extract:—

"With respect to the opinion that the phosphates of the soil owe their origin to manure, and especially to bones, I may first inquire whence do you suppose the phosphoric acid of manure, or rather of animal bodies, to come? In answer to this, some may say that it is derived from the aliments of which animals partake; others may suppose it is actually created in the animal body. If the phosphoric acid of the animal body be derived from the aliments, how does it become a constituent of those aliments? You see we must go back to that contained in plants, or rather in the soil, and this is merely proceeding in a circle. What really happens is this: carnivorous animals (the lion for example) derive phosphoric acid from the bones and flesh of other animals of the herbivorous class which they devour, these from plants upon which they feed, and plants draw it from the soil; and the presence of phosphoric acid in the soil is owing to the disintegration of rocks. Thus you perceive that phosphoric acid, as well as sulphuric acid—essential constituents of organized beings—are derived originally from the mineral kingdom. But that in bone manure you bring phosphoric acid into your fields, does not at all invalidate this conclusion, since all the phosphoric acid of bones once belonged to vegetables, and was by them derived from the soil, and from it into the soil by its separation from mineral masses. If, however, it were granted that the phosphoric acid of the animal kingdom could have had some other origin, this would not explain the circumstance that plants which have never received manure, as are those growing wild upon soil never cultivated, contain phosphoric acid; this must be referred ultimately to the disintegration of rocks.

"Finally, those of your gentlemen should have embraced the notion that phosphoric acid could be formed by the [illegible] that such an assumption is altogether unnecessary. [illegible] phosphoric acid, [illegible] of such a supposition [illegible] of matter, [illegible] soil, [illegible] soil, [illegible] soil

been a great demand for these favourite flowers this autumn, and in the north of England, where Rose-edged Piccotees have not been exhibited, great quantities have been required; as, at most of the principal exhibitions, prizes will now be awarded for them. Refer to the past few weeks for the necessary directions as to potting layers, &c. &c., taking care that when the layers are again struck, or have emitted fresh roots, that they have all the air and sun possible; watering occasionally, but not over the foliage; and at all times keeping a vigilant eye over the stock, removing every spotted or decayed leaf as soon as discovered.—*J. F. W.*

IV.—PINERIES, VINERIES, &c.

Pineries.—Much caution is necessary from this time, to prevent the atmosphere of the pits containing the succession plants from becoming too humid. Syringing should be discontinued, except on fine days, when the sun has power to raise the temperature several degrees. Whenever it is necessary to use the syringe during the winter, it should be done in the early part of the day. Pits heated by means of dung will require covering with mats at night. When covered, let every other light be slightly raised, to allow the steam to pass off. When the covering is off, it will escape through the laps of the glass. Take all opportunities of giving a little air. If it can be done every day, so much the better for the health of the plants.

Vineries.—If the Vines in pots are plunged in warm leaves or dung at about 80°, and the atmosphere kept at a temperature of 50° or 55°, the roots will be kept in advance of the tops, and the buds will break stronger in consequence. Let them be syringed frequently. Pay attention to the late Grapes, and let all decaying berries be immediately cut out. The slight fires made during the day to dry the atmosphere will leave sufficient warmth to prevent injury from frost at night.

Peach-house.—The Peaches in pots intended for the first crop should be either put into the house where they are to be forced, and kept cool for a time, or else placed in an open shed, as it is not good to commence forcing when the soil is drenched with moisture. If worms are in the pots they may be ejected by means of lime-water. No time should be lost in attending to this, if ripe fruit is required by the middle of April.—*G. F.*

V.—HARDY FRUIT AND KITCHEN-GARDEN.

Planting.—At the risk of being charged with repetition, I cannot avoid urging the importance of early autumn planting. If put off till December, scarcely any advantage is gained over planting in March or April; but a great disadvantage will be experienced, if severe weather should set in immediately afterwards. If the leaves are still somewhat greenish, the check given by raising the plants will have a tendency to accelerate the ripening of the wood, and if after watering, the bark of the young shoots should present any appearance of shrivelling, the stem of the trees may be twisted round, with hay or straw bands, and a slight shading given to the top for a few days with fronds of Fern, &c. The straw bands should be twisted hard, so as not to retain much moisture; and for tender trees, they will be as serviceable in moderating the rays of the sun in summer, as in checking the severity of frost in winter. If, in addition, the roots are well mulched with dry litter, they will continue to grow all the winter, and thus be well fitted to supply the expanding buds in spring. In many gardens, an extinction of many of the old trees should be gradually effected. I say gradually, because frequently gardeners ardent after novelty, get themselves into scrapes, by clearing away too much at a time, and thus rendering the supply deficient until their young trees come into bearing. In planting, care should be taken to select the most approved varieties. It would take too much space to particularise these in this place. The improved varieties of Pears should be introduced into every garden, either by planting, or by grafting on established trees. In addition to their other good qualities, most of them are great bearers, and produce fruit when the trees are comparatively young. Such sorts as Marie Louise, Dunmore, Louise Bonne (of Jersey), Duchesse d'Angoulême, Althorp Crassane, Glout Morceau, Knight's Monarch, Passe Colmar, and Ne plus Meuris, &c., will supply the table with delicious fruit from September to the end of February, and in places at all favourable, will succeed admirably as standards, the fruit in general being as well flavoured, though not so large as that grown against walls. The Easter Beurré, and Beurré Rance, will furnish a supply until May, and even later if the fruit is well preserved in jars. Both sorts will thrive in most places as standards, but well deserve an east or west wall. No Pears need be grown in favourable places on a south wall, with the exception, perhaps, of a Jargonelle, to supply early fruit. This, along with the Citron des Carmes, and one or two more varieties, will be quite sufficient for an early supply.

Radishes.—A last sowing may be made on a south warm border, and they will be useful if the weather continue mild. A sowing may also be made on a slight hot-bed, to be defended with a frame, hooped mats, or straw-covers; the same thing may be done with Carrots and Onions, where very young ones are constantly in demand. *Cauliflower.*—The glasses should now be put over the plants intended for the first crop next season, but the tops of the glasses should remain off in all favourable weather. There is more danger of having them coming too forward, and producing mere buttons, than in having them too late. It is better to forward them in spring, than to encourage them to grow much now.—*R. F.*

VI.—ARBORICULTURE.

Old Woods.—Continue to improve these in appearance as well as in value as much as possible, by removing all unsightly trees, and replacing them with others of more value. Lay open to view any particularly handsome trees, as recommended in late Calendars.

Coppice.—Proceed with all necessary works in this department; extirpate all valueless stuff, and replant the spaces with more profitable kinds of trees.

Young Plantations.—Embrace every fine day for forwarding all planting intended to be done before spring. This is much the best time for the general planting of evergreen trees, as in spring they are subjected to cutting, dry, frosty winds, alternately with a powerful sun. In sheltered, warm situations, and with great care, spring planting will, however, succeed.

Hedge-rows.—Continue to plant young trees, and make good any failures.

Nursery Work.—Take up and sort the young trees for planting out where required. Dig and trench vacant ground for replanting and sowing of seeds; put in some kinds now, and others in spring. Let the ground be got ready for them as soon as it is cleared of other crops.—*W. B.*

VII.—COTTAGERS' GARDENS.

As it is frequently the case that a very slight protection will save Dahlias and other favourite flowers until the middle, or even the end of November, each of the cottagers as have time and means might use some light canvas, or other slight covering, to throw over any plant particularly gay; with this several degrees of frost will be harmless. Where frost has taken effect, Lobelias, Salvia patens, and such plants, had better be got up, especially if the flower stems are killed as well as the leaves. The Salvias, in particular, ought to be left in the ground until the stems die down, as the tubers will be thereby much benefited. The best way of keeping these plants is to pot them in pots merely sufficient to hold the roots, using rather dry soil, and set them where they will be dry and cool. A few degrees of frost will be less hurtful than heat; they must get no water until they commence growing. Scarlet and other Pelargoniums for turning out in spring, ought to receive the same treatment; only they cannot be too soon taken up after their beauty is once destroyed by frost. In some cases, where the scarlet or other Pelargoniums planted out in beds are yet fresh, and have formed flower buds, the cottager might, by careful removal, obtain a few good plants for flowering in the window. Rather large pots should be used, and the plants got up with as little disturbance to the roots as possible; if they can be placed in a little close heat for a fortnight they will recover with the loss of only a few leaves. Asparagus beds, where the leaves and stems are brown, had better be cleared, and covered with an inch or two of dung. The refuse will be useful for putting round frames to keep out frost. If it can be applied dry so much the better, as it will be less liable to heat and rot. Next week I shall name a few varieties of Apples, Pears, &c., suitable for a cottage garden.—*J. McH.*

State of the Weather near London for the week ending Oct. 26, 1844, as observed at the Horticultural Garden, Chiswick.

Oct.		Moon's Age.	Barometer. Max.	Barometer. Min.	Thermometer. Max.	Thermometer. Min.	Thermometer. Mean.	Wind.	Rain.

The highest temperature during the above period occurred on the 29th and 30th, 1834—therm. 67°, and the lowest on the 31st, 30th, 1836, and 29th, 1843—therm. 22°.

Notices to Correspondents.

APPLE-TREES.—*A Young Orchardist.*—Perhaps you have planted varieties very subject to canker.‖

BEES.—*J. Argo.*—We have given so much information about Bees in the early part of this year, that we must refer you to former Numbers for the information you search for. If that is not sufficient for the purpose, you had better study some treatise on Bee management, such as Bevan "On the Honey Bee."‡

BIGNONIA GRANDIFLORA.—*H. L.*—Cut this back early in spring to within two or three eyes of the previous year's wood; and as it seldom flowers before the end of October or November, and then the flowers generally get injured by early autumn frosts, and fall off before they expand, and as the plant is also very late before it commences growing in spring, you had better encourage its early growth at that season, by placing some frame-lights over it, and mat the ends up close so as to form a kind of house over the plant; the covering may be removed about midsummer, but must again be put on before the cold nights, or first autumn frosts occur.¶

BOOKS.—*Leyton.*—We have no book on the Botany of the Himalayas, except Royle's Illustrations, in 4to. with many plates. That work is indispensable to botanists in the north of India.——*Z.*—The small edition of "English Botany" contains figures of all our wild flowering plants. There are no plates to Sir W. Hooker's Works, except those which are published with them.——*J. Steel.*—Mackintosh's "Practical Gardener."——*S.*—Petzholdt's "Lectures to Farmers on Agricultural Chemistry."

CHARCOAL.—*A. Z.*—Soft-wooded plants make the best charcoal. Pile the branches neatly in a large heap; cover it over with sods, leaving a hole at the top, and another at the bottom; light it at the latter, and when fairly in a blaze stop the two holes, and watch the heap to see that no flames burst through the sides.

HYACINTHS.—*A Cockney.*—Read what we wrote a few weeks ago about Hyacinths in glasses: keep them in the dark in a warm place till roots appear; a few grains of salt or guano sprinkled in the water can do no harm.

INJURY BY GOATS TRESPASSING.—*A Subscriber.*—You may distrain the goats doing damage on your premises, and impound them. It is very doubtful whether, under the Malicious Injuries Act (7 & 8 George IV., c. 30, s. 24), magistrates can convict a person who, even after notice, merely *suffers* his cattle to wander into the grounds of another and do injury there. Magistrates, however, constantly assume jurisdiction, and convict where a person actually *turns or drives* his cattle into his neighbour's land, and they do damage there. You had better, at all events, apply to the magistrates who sit for your district, and request them to act in the matter.—*W.*

INSECTS.—*J. B. W.*—The active insects on the Ixora are the pupæ and image of a Psocus, and not the males of the Coccus, which you will see represented in Curtis's Brit. Ent., pl. 717.*R*——*J. C. M.*—Your Palmer-worm is the larva of Agrotis exclamationis.*R.*——*R. W.*—Thanks for the flies. As I expected, a vast number of them are a species of Chlorops, and may be one of those whose larvæ have done considerable injury to the Corn crops this summer.*R.*

MELONS.—*A Young Reader.*—The Melons to which you refer, (p. 688) are suspended from the wires to which the Vines are tied. The house is of the common form, with a lean-to roof, having a pit 2½ feet wide running along the centre; this is heated below by means of a hot-water tank, over which the Melons are planted. There is no crop in the house, as the Vines were only planted this season; the foliage, however, extends over as much space as if the Vines were in bearing. If a "Young Reader" wishes to try the plan, let him in the beginning of next July plant out some Melons in a vinery containing a late crop of Grapes. He will find that they will go on well together, as by the time the Grapes are beginning to ripen, the Melons will have done swelling; and then the dry warm atmosphere which must be kept up to ripen the Grapes, is just what is required for the Melons. *G. F.*

MORPHOLOGY.—*A Constant Reader.*—You should use your eyes, and then you would find that the Purslane had flowers, although very small ones; no perfect plants can seed without flowering first. The seed had, no doubt, been mixed in the seed-shop where you bought it—a common trick.

NAMES OF FRUIT.—Our correspondents are entreated to observe that much space and time would be saved if those who send fruit for names would forward along with them a list containing the numbers and such names as they may have for their varieties. In many instances these would probably only require a little correction.——*S. W. G.*—1, Aston Town; 2, White Doyenné; 3, Moorfowl Egg; 4, Golden Rennette.‖——*R. Tatham.*—No. 1, which you had for the Beurré Spence, is the Brown Beurré; and for the Winter Rousselet, No. 2, you have got the Bishop's Thumb. The small ovate pale-yellow sweet Apple, called the Small Stalk, is not known to any other name.‖——*W. S. J.*—1, Norfolk Beaufin; 2, Herefordshire Foundling; 3, Kirke's Golden Pippin; 4, Winter Nelis; 5, Beurré de Capiaumont.‖——*W. E.*—Blenheim Pippin.‖——*F. Darby.*—Not the Colmar, but St. Germain; the other is the White Doyenné. Specimens of both varieties unusually large, doubtless, as you observe, in consequence of having your fruits excessively thinned.‖——*St. M. B.*—1, 4, Lamb Abbey Pearmain; 3, Keswick Codlin; 7, Kirke's Golden Pippin; 8, probably Black Annett; 9, Blenheim Pippin; 10, Yorkshire Greening; 11, Large Hunthouse; 12, Hollandbury; 13, Court of Wick.‖——*A Constant Reader.*—1, Winter Bon Chrétien; 2, Brown Beurré; 3, Passe Colmar; 4, Bishop's Thumb; 6, Uvedale's St. Germain; 7, Marie Louise; 8, Winter Nelis.‖——*H. Y.*—1, Beauty of Kent; 2, Hollandbury; 3, Northern Greening; 4, Gansel's Bergamot.‖——*Thomas Oread.*—Flemish Beauty.‖——*A Subscriber.*—Blenheim Pippin.‖——*T. Barnes.*—Uvedale's St. Germain.‖——*Rhoden.*—Beurré Diel.‖——*Russet.*—Your Apple appears to be Logan's Pearmain, in good perfection.‖——*A Constant Reader.*—1, Minchall Crab; 3, Nonsuch.‖——*S. H.*—Nailing the tickets upon your fruit with iron tacks, is not so secure as might be supposed. The acid juice partially dissolves the iron, exudes and obliterates the numbers, or the nail loosens as the surrounding tissue wastes, and drops out. Of those you sent there were found attached—2, Winter Pearmain; 5, Blenheim Pippin; 8, Downton; 11, Posse Colmar. Some well-coloured Pearn's Pippin and Golden Reinettes were observed.‖——*Miss. W.*—The Seedling Apple is handsome and sugary; but although good it will not bear comparison with the Golden Reinette, which becomes fit for use at the same time.‖——*J. D.*—1, an exceedingly handsome, large, finely-coloured Apple, not known; it deserves particular notice; 3, Hughes's Golden Pippin; 4, Cockle Pippin; 6, Bedfordshire Foundling; 9, Verte Longue; 10, Coe's Fine late red Plum.‖

NAMES OF PLANTS.—*C. D.*—As far as we can judge from flowers jammed to pieces among cotton wool, your plant is Oncidium trulliferum; but it *may* be now. We never saw the fruit of Stephanotus; no doubt it is poisonous.

PEACH-TREES.—*Querist.*—These may be partially pruned as early as October. At Montreuil, such bearing shoots as are not required for the extension of the tree are cut out as soon as the fruit is gathered.‖

PEARS.—*Querist.*—There can be no advantage in raising Pear-trees from cuttings; on the contrary, the wood of cultivated varieties is not so perfect as that of the wild species; consequently, it is not so well adapted for enduring vicissitudes. The varieties of Pears you name, Marie Louise, Napoleon, Beurré Diel, and Glout Morceau, Bergamot, should not be gathered until they readily part from the spur.‖——*H. W. B.*—The Pear you sent possesses all the excellence you ascribe to it, and will be specially noticed as soon as possible.‖

PEAR-TREES.—*W. S. I.*—The spots on the leaves are occasioned by the Pear-tree Blister Moth, on which you will find an excellent article, with a figure and description, by Mr. Curtis, vol. i. p. 260. Sweep up and burn every leaf, carefully remove the surface soil from around the tree, and substitute fresh. With regard to your list of Pears, you will probably find the Beurré Spence to be the same as some of the other varieties you enumerate, all of which are good.‖

SPRUCE BEER.—Will any of our correspondents have the goodness to inform *J. C.* how this wholesome beverage is best made? Is Dantzic Spruce the same?

STOVE PLANTS.—*Aliquis.*—Musa Cavendishii, Mangoes, and Guavas offer you the best chance of ripening tropical fruits. You may procure them of, or through, any of the great London Nurserymen. Among gay stove plants, take Euphorbia jacquiniflora, all the Achimenes, Poinsettia pulcherrima, Bignonia venusta, Passiflora Loudoni and quadrangularis (a fruit), Ixoras, Thunbergias, and Oncidium Lanceanum.

STRAWBERRIES.—*M. A.*—Small round stones will not keep air from the roots; it will find its way freely through their interstices. We recommend them in preference to tiles, when they can be had—1st, because they cost nothing; and 2d, because they look very neatly.

VINE-BORDERS.—*Rusticus.*—The main bulk of the compost for a Vine-border should consist of rich turf; to which may be added bone-dust and cow-dung. You may plant a Vine for each sash, and allow three cubic yards of compost for each plant; this will admit of the border being ten feet wide; or, with 48 cubic feet, you may form it only 6 feet wide in the first instance, and add 6 feet more as the Vine-roots extend, which will prove advantageous. Paving, or any other covering which would prevent the access of rain to the roots in summer, is objectionable. If you have strong and weak growing sorts, and can afford separate beds for each, so much the better. The rod system of pruning is best for large bunches, and for some varieties; close spurring for producing on the Black Hamburgh, and some others, a heavier crop consisting of a greater number of smaller bunches.‖

WISTARIA SINENSIS.—*A Subscriber.*—Prune this about the beginning of March; cut the leading shoots about half way back, and spur the others in rather short.¶

MISCELLANEOUS.—*S. B.* 369.—We regret to say that there is no sort of demand for your talents; the field is a very small one, and is already fully occupied. Teaching is the only mode of turning such talent to profitable account.——*A. M.*—The best season to plant Belladonna Lilies is the beginning of August.——*Querist.*—Cut the strong shoots of your China Roses about half way down. Stop and cut back the long shoots of Climbing Roses, if not wanted to cover a large space quickly. Spruce Firs make an excellent hedge for shelter.¶——*A Lady.*—Your dark cellar is too cold for the Hyacinth roots to show themselves quickly. Can you not wrap the glasses in some old baize, or place them where they get a little artificial warmth; that is essential. Water your turf with lime-water, prepared by steeping fresh lime in water for 24 hours, and draining off the clear fluid. A peck of lime is enough for a hogshead of water.——*A. M. S.*—Your plant of Oleander has probably been allowed to get dirty, which is the cause of white scale forming on it.¶——*A. Z.*—The leaves of Pinus Pseudo-strobus sent are by no means uncommon; most of the strong-growing kinds, if they happen to lose the leading point of the young shoot during the growing season (which is frequently caused by the Pine-beetle), will lose the power of elongating, and consequently to form those monstrous leaves, especially if the plants are young and vigorous.¶——*A Young Beginner.*—Bupbane ciliaris, Trichonema speciosum, and Cyrtanthus odorus are greenhouse bulbs; Griffinia hyacinthina is a stove bulb. You had better not start them till February.‖——*H. D.*—Ipomœa Learii is a perennial. Your plant on the back of your conservatory is perhaps too far from the glass, or shaded by other plants. Train it to a rafter where it will be within a foot of the glass, and it will flower freely.‖——*R. J. W.*—We do not know to whom the Pansy belongs noticed under the initials *Z. A.**——*W. B.*—You can hardly hope to save your Cape plants without better means than you possess. Nevertheless it may be worth trying whether they will not survive where they are by having six inches of sand (sea sand will do) placed well over the roots, and some Spruce branches tucked in among their shoots.

SEEDLING FLOWERS.

FUCHSIAS.—*G. S.*—Your seedling *Junius* appears to much greater advantage on the plant, the foliage of which is handsome, and the habit of the plant good; the flower is stout and handsome, but we are still of opinion it carries too much colour in the tube and sepals for the vermilion corolla.*

PANSIES.—*W. M.*—The Pansy sent is a good specimen of form, but it wants substance, and is common in colour.*

VERBENAS.—*A Constant Reader.*—Your specimen is a good variety; it is not novel in colour, but the size of the light centre makes it attractive.*——*W. W. W.*—Your seedling is a large and handsome variety of a bright rose colour.*——*G. S.*—Your specimen is large, and carries a fine head of bloom, but it appears to want novelty of colour.*

DR. HALLETT'S DRY SOLUBLE FERTILIZER'S are, considering their power, the cheapest Manures in use, for they are entirely composed of the Phosphates and other Salts of Ammonia, and other acknowledged powerful fertilizers. They are fairly before the Public as tried things (see No. 23 of the *Gardeners' Chronicle*, &c.). 1 cwt. of either has been found equal to nearly 30 tons of ordinary horse-manure. They are applicable to all sorts of field and garden crops. No. 1 for heavy top growth, as Corn, Hops, &c. No. 2 is for all roots, and a sure preventive of the Fly in Turnips. Price of each, 16*d.* per ton, or 12*s.* per cwt.

DR. HALLETT'S CONCENTRATED LIQUID FERTILIZER is extensively used by Gardeners for improving the size and flavour of fruits and vegetables, and the colours, and perfecting the seed of flowers. Sold in quarts at 1*s.* 6*d.*, and in bottles, six times the size, at 7*s.* 6*d.* Each quart requires 32 gallons of water, to reduce it for use.

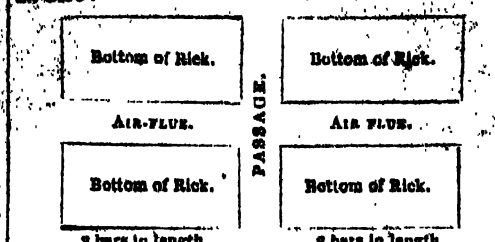
Agents for the above. London—Mr. Fothergill, Thames-street; Mr. G. Hallett, the Factory, Broadwall, Blackfriars; Messrs. Warner & Warner, 26, Cornhill; Hurst & M'Mullen, 6, Leadenhall-street; Wrigtanly, Poultry; Pace & Co., St. Peter's Alley. Norfolk—Bullard and Watts, Norwich. Suffolk—Mr. W. Revans, Yoxford. Leicester—Mott and Co. Gloucestershire—Mr. Betterton, Fairford. Devonshire—Mr. Seward, Plymouth. Wilts—Mr. G. King, Devizes. Glasgow—Mr. D. T. Jackson, Hartlepool. Sunderland, Stockton, and Newcastle—Pace & Co. Dundee—Green and Co. Further respectable Agents wanted.

The Agricultural Gazette.

SATURDAY, OCTOBER 26, 1844.

MEETINGS FOR THE TWO FOLLOWING WEEKS.
THURSDAY, Oct. 31—Agricultural Imp. Soc. of Ireland.
WEDNESDAY, Nov. 6—Agricultural Society of England.
THURSDAY, Nov. 7—Agricultural Imp. Soc. of Ireland.
FARMERS' CLUBS.
Oct. 28 - Chepstow, Wickham Market, Yoxford.

In a former Number we called attention to the numerous crops of Barley which are yet in the field, and endeavoured to point out how such a circumstance might have been prevented. Whatever effect our advice and the experience of the season may have on our management for the future, our present duty is unquestionably to make the best we can of a bad bargain, and to contend to the utmost of our means with the disadvantages which are before us, from whatever cause they may have resulted.



One of these disadvantages—THE DIFFICULTY OF SECURING THE CROP—is now felt pretty generally. The state of the crop, owing to its mixture of ripe and half-ripe straw, is such that it requires much more than ordinary fine weather; and, in the second place, the season is so far advanced that instead of a continuation of the fine warm weather necessary to enable us to secure the crop quickly, we have frequent showers, heavy fogs, and short days. To expose our crop for so long a period with a certainty of fickle, and a *probability* of stormy weather before us, is a matter of such imminent risk that it becomes a question of duty with all who are thus situated to ask, Is there no method of avoiding it?

In our opinion, the following method, which has been often successfully employed, in securing grain in difficult and adverse seasons, will be found capable of diminishing in a very great degree the risk alluded to, and will enable us to harvest our backward crops without the delay and danger of more than a day or two's *fielding*.

Take the first opportunity after the grain is cut, when the straw is dry—*i. e.* free from rain or extraneous moisture—to secure the crop in the following manner:—Place four sheep bars or hurdles in two parallel lines, leaving a space of about 24 inches wide between the rows. This will form a double fence about 6 yards in length. Upon each side of the double fence spread a bottom of thorns, and upon this, place a course of sheaves *with the heads towards* the sheep bars. After a few courses of sheaves have been laid in this manner put an occasional one with the sheaves longitudinally. Continue to build up the wall of sheaves on each side of the bars until you have got 2 feet above the bars; after which lay a course over the passage between the bars, and roof up both sides to the centre. Cover the roof with old thatch or loose straw, and bind it well down. This may be done without treading on the rick, as the more lightly the sheaves lie, the better the work is.

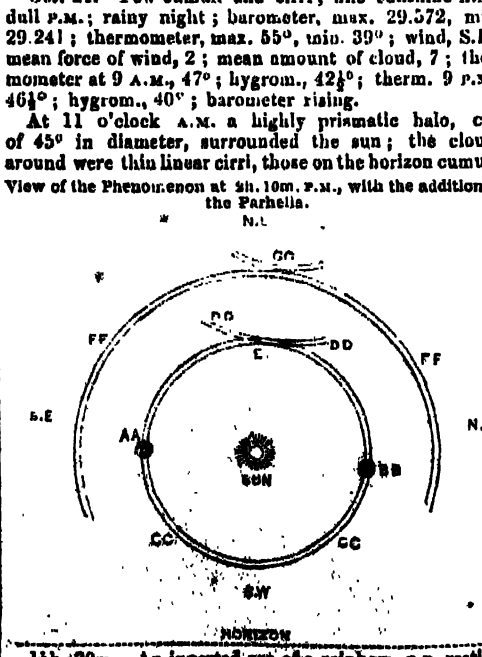
This being done, we have a rick, through the middle of which there is a passage or flue 5 feet deep by 2 feet wide, and as the heads of the sheaves are generally towards the passage, the air has free access to the grain—in fact, there is a continual current of air passing through every part of the rick; for as the sides of the rick are only one course of sheaves in thickness, there is a multitude of flues leading into the main passage, through the whole of which there is a continual draught; by which arrangement the grain gets all the benefit of exposure to the atmosphere, without any of its risks.

The rick which we have now described—two bars in length—will hold the produce of half an acre of land, and when properly built will harden and weather it nearly as soon as if it were in shock. By prolonging the double row of bars a rick of any size may be formed. We should advise, however, that every half acre should be put in separate lengths, *i. e.*, that communication with the other ricks should be broken off by a passage 2 or 3 feet wide, at the end of every alternate bar; this passage, running at right angles with the longitudinal one, would materially increase the circulation of air. The following is a ground sketch of the rick containing the produce of an acre:—

Any number of these ricks, it will be seen, may easily be made, and the air will have equal access to every part; so that in the course of a month or five weeks the grain which has been so secured, *however raw it may have been*, will come out fit for the stack-yard or the barn.

If we claim any merit for this method of securing grain in an adverse season, it is on the score of utility, not of originality. On the contrary, one of its chief recommendations is, that it has in several cases been employed with perfect success, and that there are several modifications of the same principle in common use. Among these we may name the frame-work chimney, which is so generally used in all stacks in Scotland, and that which is used in hay-stacks in England. Perhaps, however, the most original and simple illustration of the principle by which we now propose to secure grain in difficult times, is that of setting *the stack astride of a Quick-thorn hedge;* a practice which has long been honoured by the approbation of our grandsires, and which derives its utility from its admitting a current of air into the stack.—*H.*

PARHELIA, &c.,



Seen by E. J. Lowe, on 20th and 21st October, 1844.

On the days above stated I noticed very rare and interesting atmospheric phenomena, on which the following are my remarks. For two or three days prior to the 20th the weather had been showery with slight frosts at night. 20th—barometer, max. 29.351, min. 29.248; thermometer, max. 53°, min 40°; wind, S.W.; mean amount of cloud, C^{S}_{Cm}; few cumuli; fine sunshine A.M.; nimbus and cirrostrati, dull, with few drops of rain at 5 P.M. At 8h. 30m. P.M. a brilliant halo of 45° encircled the moon; at 8h. 40m. a mock moon, of a pale silvery hue, shone out of the halo on the E. side, and on the horizontal level of the moon; this continued visible till 8h. 50m. P.M.; the lunar halo remained all night. 8h. 30m., noticed a very brilliant and beautiful display of Aurora Borealis: a broad stream of flame extended from the N.E. horizon, through the constellations Auriga, Capella, Perseus, Cassiopeia, Cyghus, Lyra, and disappeared in the horizon in W., near Serpentarius; this band flickered brightly for 15 minutes, when it vanished. 8h. 40m.—a flame crossed (through the broad flame) from the Polar star through Perseus. 8h. 45m.—another stream of light extended through Ursa major, Ursa minor, to Draco: at this time the flame from the Polar star to Perseus was very vivid. During the whole of this display the horizon from N.E. round by N. to N.W. appeared as one continual flame, not glaring upwards, but along the horizon; therefore the chief portion of the light was reflected from below. At 9 o'clock the Aurora Borealis vanished, excepting a slight glimmering now and then, which would scarcely have been perceived had not the phenomenon been noticed before. At 11 P.M. the stars shone through a haze, which gave them the appearance of being surrounded by burrs.

Oct. 21.—Few cumuli and cirri; fine sunshine A.M., dull P.M.; rainy night; barometer, max. 29.572, min. 29.241; thermometer, max. 55°, min. 39°; wind, S.E.; mean force of wind, 2; mean amount of cloud, 7; thermometer at 9 A.M., 47°; hygrom., 42½°; therm. 9 P.M., 46½°; hygrom., 40°; barometer rising.

At 11 o'clock A.M. a highly prismatic halo, C C, of 45° in diameter, surrounded the sun; the clouds around were thin linear cirri, those on the horizon cumuli.

View of the Phenomenon at 2h. 10m. P.M., with the addition of the Parhelia.

11h. 30m.—An inverted arc of a rainbow, D D, resting on the summit of the halo C C appeared. At the point E, where this rainbow cut the halo, it was almost as brilliant as the sun itself. This lasted till 0h. 15m. P.M., when it vanished, together with the halo.

1h. 15m.—The halo C C and inverted arc of rainbow D D again appeared; the latter was very distinctly prismatic, having the red colour next the sun. From this time until a little after 2 o'clock no change worthy of mention, excepting that the inverted rainbow kept increasing and decreasing in brightness, and every now and then so brilliant that you could scarcely look at it.

2h. 1m.—A Parhelion, A A, of a silvery colour, appeared in the S.E. side of the halo C C, and on the horizontal level of the sun.

2h. 5m.—Mock-sun vanished; the portion E of inverted rainbow D D was extremely bright.

2h. 9m.—A halo, or, more properly speaking, a rainbow, F F, became visible, surrounding the upper or N.E. half of the halo C C, at a distance of 15° from it; this was of a silvery hue.

2h. 10m.—Another inverted arc of a rainbow, G G, appeared at the vertex of the rainbow F F. The inverted rainbow D D was brilliant in the highest degree. Both the inverted rainbows, D D and G G, were situated and opened in a direction to the N.E.

2h. 15m.—Atmosphere very dense. Inverted arc of rainbow G G, and rainbow F F, and S.E. side of the halo C C, disappeared. Inverted rainbow D D very brilliant. Few cirrostrati below the sun, and cumuli round the horizon.

2h. 18m.—Halo C C very indistinct. Inverted rainbow D D still very bright.

2h. 26m.—Inverted rainbow D D vanished. A faint parhelion B B was visible in halo C C, on the N.W. side, and on the horizontal level of the sun; this lasted till 2h. 30m., when all vanished. Scud and cirrostrati covered the whole visible surface of the sky, and became more dense every minute. The clouds were evidently formed on the spot, and plainly by the vapours reaching the cold current. Overcast, close evening; rainy night.

Excepting the halo C C and inverted rainbow D D, which were prismatic, the colour was pale silver throughout.

A very similar phenomenon to the one seen to-day was noticed by Hevelius at Dantzic on 30th March, 1660, only this was parhelia, and that described by the Polish astronomer parselenæ.—*E. J. Lowe, Highfield House, Lenton, Nottinghamshire.*

GEO-AGRICULTURAL NOTES ON SOUTH GLOUCESTERSHIRE.

(*Continued from page* 691.)

Mountain Limestone.—This rock occupies a considerable portion of our district. It occurs in a tract of a horse-shoe form, and of considerable breadth, underlying the millstone grit, and overlying the strata of the old red series from Sodbury by Wickwar, Cromhall, and Alveston, as far as Almondsbury. On going southwards from Almondsbury we pass over a district of lias clay, which here appears to overlie the limestone, for, immediately beyond Henbury, we again come upon that rock, forming the range of hills which extend towards the Avon beyond Kingsweston. From this spot it widens out between Westbury and Filton, in a southerly direction. A considerable tract of this rock is exposed south of Bristol, comprising Clifton and Durdam Downs, &c. The rock here is much intersected by wide veins of calcareous spar, which is quarried and broken down to a fine gravel and used for rough-casting buildings. The mountain limestone, more than any other rock in the district, seems to have suffered violence. The fault on Alveston Down, that at Doynton, the extensive ravine at Clifton through which the Avon flows, a similar one between Wick and Doynton, through which the Boyd runs, another at Tortworth Park, and a fourth in the grounds of Blaize Castle, Henbury, all occur in this rock. They are productive of the finest and most picturesque views in the county. The mountain limestone does not form a good building stone, being too splintery for the mason's chisel. It forms an excellent road material, however. The only rock, indeed, which can compete with it in the district for that purpose, is the trap rock of Damory, near Tortworth, but this, though perhaps a tougher and more durable material, does not form nearly so smooth or so excellent a road. This rock is also the best source of lime for building and other purposes in the county; it burns, when pure, as at Cromhall, of a perfectly white colour.

Agricultural Character of the Mountain Limestone.—The surface of this district, with the exception of instances just alluded to, is uniform and regular. It has frequently a bare and bleak aspect, because of the want of hedgerow trees, and because of the frequent occurrence of downs and commons. The general level of the district, too, is higher than that of the surrounding country, and it is thus more exposed to the weather. The Beech and the Ash are the trees of most frequent occurrence on it; the Elm is also occasionally seen. The commons are dry, the pasture on them close but sweet. This district is about one-half under arable culture. The pasture-land is easily burnt; there cannot be too wet a season for the soil where it is shallow. An average crop of about 18 cwts. of hay per acre is cut. The soil on the arable land is full of angular fragments of the rock, and is generally very thin. It is, however, a good calcareous loam when of any depth, and its natural lightness, increased by the numberless fragments of stone occurring in it, renders it an excellent Barley soil. The rotation adopted is one of four years' duration, the same as that adopted on the millstone grit in the neighbourhood; 1st year Wheat, 2d Barley, 3d Seeds, 4th Potatoes. Turnips are sometimes grown instead of seeds, and frequently that crop is omitted altogether. In that case it would be difficult to find a more exhausting succession of crops. Everything is carried off the land, and very little return is made to it. The grain is taken to

Bristol, the straw, sold as litter, or thatch, is taken there too, and the Potatoes also supply the Bristol market. The loads of dung which are brought back in the waggons on their return from Bristol can form no equal return for the crops thus carried away. The average crop of Wheat per acre is about 20 bushels; of Barley 32, and of Potatoes 60 sacks. Eight tons of the latter crop is considered an excellent crop; it is equal to about 80 sacks.

The soil on this rock is sometimes limed by some: this is said to do good; and by others it is said to be of no use at all. It is a general practice on those farms which lie over the clay and slate alternating with this rock near Tythington and Tytherington; the soil is there of a cold clayey nature. The district of this rock between Elberton and Lyttleton differs from that on the hill in being more sheltered; it is covered with the Elm and the Ash in the hedgerow; the soil is also generally deeper, and the land more generally in pasture. With these exceptions it is similar to the rest of the formation.—*M. S.*

ON LIMING LAND.

[The following analyses, for the Monmouth Farmers' Club, by Mr. Phillips, of the Ordnance Geological Survey, show what great variety exists in the composition of limestones within but few miles of one another.]

No. 1.—Limestone, Great Doward, Herefordshire.

Carbonate of lime	56.8
,, ,, magnesia	39.2
Earthy matter and oxide of iron	4.
	100

No. 2.—Limestone, Stanton, Gloucestershire.

Carbonate of lime, with a trace of oxide of iron	54.6
,, ,, magnesia	44.
Earthy matter and oxide of iron	1.4
	100

No. 3.—Limestone, Whitecliff, Gloucestershire.

Carbonate of lime	56.8
,, ,, magnesia	41.9
Earthy matter and oxide of iron	1.3
	100

No 4.—Limestone, Stow Green, Gloucestershire.

Carbonate of lime	98.6
Earthy matter and oxide of iron	1.4
	100

No. 5.—Limestone, Ifton, Monmouthshire.

Carbonate of lime	99.3
Earthy matter and oxide of iron	.7
	100

Result of the use of the Stow Green Lime put on in a caustic state in September and October upon the dry sandy meadows along the bank of the Wye (except No. 5) extending about two miles from Whitebrook to the village of Landogo, Monmouthshire, No. 1 being near Whitebrook, and No. 6 adjoining the churchyard at Landogo. Nos. 1, 2, and 3 were covered with rotten dung at the rate of 20 yards per acre between the years 1830 and 1834; the other meadows have not had any manure in the memory of man. The average produce of hay from these meadows when cut in season (without manure) for the last 20 years has been only from 10 cwt. to 14 cwt. per acre. A part of each meadow was left without lime, that a fair trial might be made, and the whole of the trials (except No. 6) were taken within three yards of each other; indeed many of the trials were within a foot; the line where the lime was put being so strongly marked that a perfect stranger might tell which part was limed and which part not. The best plan is to put the lime in heaps of one or two waggon-loads, covering the heaps with a thick coat of earth till it is slaked, and then to haul or wheel it out in a caustic state, spreading it out of the cart or barrow. If the place where the loads are put down is shovelled out clean, there will in those places be the strongest crop of Grass the following summer. Stow Green is within three miles of these meadows, and the price of the lime being 4*s.* 6*d.* per dozen, or 1½*d.* per bushel, the cost of manuring at the rate of 108 bushels amounts to 27*s.* per acre.

No. of Meadow.	The Autumn when Limed.	Imperial bshls. of Lime put on per Impl. acre.	What year mown after being Limed.	Quantity of hay on the limed part per acre more than on the part not limed.	REMARKS.
				Cwt.	
1	1832	108	1st	42	From this trial it appears the more lime used the more Grass.
		144	do.	102	
		216	do.	196	
2	1833	136	2d	20	The limed part of this meadow may now be traced by a stranger.
			4th	142	
			7th	64	
3	1833	108	2d	106	
			3d	20½	
			5th	11	
4	1833	108	1st	44	
5	1833	136	3d	22	This piece has a turn in it, and adjoins the turnpike-road, near the village of Landogo; although the part limed had the manure drawn from eight small tenements many fold more for the space of years than the part not limed, the limed part being very superior in herbage and produce. By turn, in this piece is a block of Grass between the limed part the length will not touch the other.
6	1833	108	2d	20½	

The lower part of No. 3 was this autumn (for the first time) dressed with lime from Stow Green, varying from 108 bushels up to 360 bushels per acre, and with lime from Whitecliff at the rate of 72 bushels per acre, the quarters of an acre adjoining, with a strip in the centre without anything put on. From a trial made this autumn it appears that lime in these meadows sinks at the rate of about one inch per annum. It is a singular fact that the same quantity of lime per acre, mixed with 30 yards of ditch-earth and road-scrapings, put upon some of these meadows, has not produced as great a crop of hay as the same quantity of lime put on in a caustic state. A trial was made in one of these meadows with 20 cart-loads of unfermented, or raw horse-dung per acre against 20 yards of rotten dung. The result was decidedly in favour of the raw dung the first year; but the rotten dung had the advantage the second year, when the trace of both was nearly lost. A trial has been made in one meadow with scavengers' manure from Bristol, at the rate of 20 tons per acre, and although it was delivered upon the bank at 3*s.* per ton, the increase of hay did not pay half the cost.—*Communicated from the Report of the Monmouth Farmers' Club, by R. W. Purchas, Esq.*

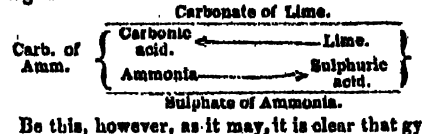
SKETCHES OF EAST LOTHIAN HUSBANDRY.

Oats.—The varieties of this grain commonly cultivated in East Lothian, are the Potato, Hopetoun, Early and Late Angus, Sandy Dun, and several others. The first-named kind, which was, it appears, introduced into this county in 1801, possesses the greatest reputation; and although it is not so well suited to inferior soils and elevated situations as some of the others, its grain is more plump, weighs heavier, obtains a better price in the market, and yields a greater weight of meal than any other variety grown in this quarter. Another very extensively cultivated kind is the Hopetoun Oat, selected and propagated by Mr. P. Shirreff, late tenant at Mungoswells, in this county. It affords a greater quantity of straw than the Potato Oat, but is later in ripening. The Early Angus is also much esteemed, and produces a large proportion of straw, which is an important consideration here. The preceding four varieties are those held in the greatest estimation, and most extensively cultivated in the low and fertile parts of the county. The Sandy Oat is also grown to a considerable extent. The Dun Oat was introduced from Fifeshire; it thrives better than most other kinds upon poor soils, ripens early, and yields a good proportion of meal. It is, as the name implies, of a dun and dirty gray colour, resembling in appearance the white kinds that have been injured by heating. Besides those enumerated above there are several other varieties of the Oat partially grown in different parts of the county, such as the Poland, Blainslie, Flemish, Zealand, &c. The following Table exhibits a comparative view of the result of an experiment made with four different kinds of Oats by Mr. Brodie, Abbeymains, as detailed in the nineteenth Report of the East Lothian Farming Society. The quantity per acre sometimes obtained in East Lothian will also be perceived from the annexed Tabular view of the result of Mr. Brodie's experiment. It will be observed that the Potato Oat produced 90½ bushels per Scotch acre; the Hopetoun, 88 bushels; the Flemish, 86 bushels; and the Zealand, 85½ bushels.

Names.	Acres.	Grain Bushels.	Weight, Imperial lbs.	Straw, lbs.	Per Scotch Acre. Bushels.	lbs.	Per Bushel, lbs.	Straw, lbs.
Hopetoun . .	1.07700	174	7344	11,008	88	3713	42 2	5566
Potato . . .	1.88850	180	7927	9795	90½	3996.14		4927
Flemish . .	1.91300	165	7166	9900	86	3756	43.5	5122
Zealand . .	1.79980	154	6780	7824	85½	3764	44	4350

Oats are most generally sown after Grass, which has lain for one or two years, the land being ploughed the previous winter, or as early in spring as the state of the weather and the labour of the farm will admit, in order that it may receive some of the winter's frost, which materially facilitates the process of harrowing. This is especially the practice on strong clay lands. On the lighter and more friable class of soils, where the furrow-slices are liable to be too much levelled down by the influence of the weather, many farmers defer ploughing a part of the lea until about seed-time; the seed is then sown as soon as practicable after the land has been ploughed. Oats are sometimes, but not frequently, sown after summer fallow, but often succeed Turnips. Oats are also, under particular circumstances, taken after Oats; this, however, but rarely occurs, and may be considered a deviation from the general practice.

Oats are for the most part sown broadcast, either by the hand, or with the broadcast sowing-machine; but where there is a great prevalence of annual weeds, particularly of the Wild Mustard or Charlock (*Sinapis arvensis*), it is not uncommon to sow in rows with the drill-machine, which admits of the land being afterwards hand or horse-hoed, and the weeds destroyed. In this case, the surface is first well reduced by the action of the harrows, after which the seed is deposited in parallel rows across the ridges. A single turn with the harrows is then given, and the land water-furrowed.



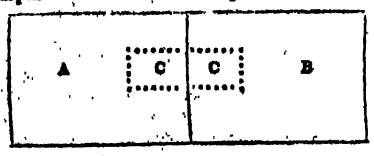
The period of sowing Oats is usually from the beginning of March to the middle of April; but this, of course, is mainly regulated by the weather. In some seasons the sowing of the Oat crop is concluded by the end of March, whilst in others comparatively little is done till the month of April. The quantity of seed varies according to the quality of the land, variety of seed, and other circumstances, from 3½ to 4½ bushels of the Angus kind, and from 3 to 3½ bushels of Potato Oats per acre. The latter variety tillers better than the former, or indeed any other kind, which renders a small allowance of seed sufficient.

The produce obtained per acre varies very much with the season. In 1832, which was a very productive year in this county, many farms averaged upwards of 7 qrs. per acre. A field in one farm which was summer-fallowed and sown with late Angus Oats at the rate of 2½ bushels to the acre, yielded, as I have been told by the tenant, 13 qrs. per imperial acre. These are, however, altogether extraordinary crops; 5 qrs. are regarded as a good crop, but 4½ bushels are reckoned to be a fair average produce per acre throughout the county. In the low and fertile parts, the average is generally greater, but in the upland districts it is considerably less. Angus Oats weigh generally about 43 lbs. a bushel, and Potato Oats from 44 to 46 lbs. A bushel of Potato Oats usually yields 3 pecks of meal of 6½ lbs. each.—*T. Sullivan.*

ON THE ACTION OF GYPSUM.

The Number of the *Agricultural Gazette*, for Oct. 13, contains a communication from Prof. Henslow, qualifying the statement which it was asserted he had made respecting the fixation of ammonia by gypsum. No very strong recommendation of gypsum appears to have been given, and, in the absence of some expected returns, Prof. Henslow contents himself with directing the attention of practical men to this important agricultural experiment. The theory—for such at present, perhaps, it must be termed—will scarcely be looked upon as very plausible, since Sir J. Herschell says of it, "I never tried the experiment, and have even some small doubt of the fact that carbonate of ammonia in a liquid or vaporous state will decompose solid crystallised sulphate of lime, though I do not deny that it may."

In order to arrive at some practical conclusion on the subject, I placed about a tenth of a grain of gypsum and an equal quantity of carbonate of ammonia, with two or three drops of distilled water, on the stage of my microscope, and the result leads me to think that we may safely go even beyond any measure of praise which gypsum has hitherto received. A double decomposition of the two bodies was immediately effected. The sulphuric acid of the gypsum took up the ammonia, and after a few minutes prismatic crystals of sulphate of ammonia were abundantly formed, while the carbonic acid, liberated from the ammonia, formed minute crystals of carbonate of lime, which thickly clustered round the dissolving portion of carbonate of ammonia. Is it right to infer from this position of the crystals, which the microscope discovers, that ammonia has a greater affinity for sulphuric acid than carbonic acid has for lime? or, if the reverse were the case, should we not find the newly-formed crystals of carbonate of lime congregating round those of the sulphate? This state of things may be illustrated by the following diagram:—



Be this, however, as it may, it is clear that gypsum may be most successfully used for the fixation of ammonia. I have tried the experiment on a larger scale, by placing 100 grains of each of these compounds in 3 oz. of distilled water for about 30 hours, and on evaporating the filtered supernatent water to dryness, I obtained 67 grains of sulphate of ammonia. I find, also, that sheep-dung, incinerated, and then similarly treated with sulphate of lime, yields a soluble sulphate at the expense of the gypsum; and I therefore only add, that the result of these experiments has induced me to order three tons of gypsum for my glebe farm, though but a few days ago I refused to make a purchase, under the impression that the advertisements of dealers are, like American stories—remarkable if true.—*J. B. Reade, Stone, Aylesbury.*

Home Correspondence.

Scotch and English Farming.—I have seen several attacks on English Farming in the *Chronicle*. Will you permit a Scotchman who has been over the greater part of Scotland, and lived many years in the south of England, to make a few remarks relating to the subject? Your correspondent, Mr. Russell, says, if England were to be cultivated the "same as Scotland, the land is capable of yielding double the increase;" and he contrasts Sussex with the "high lands of Scotland." Now, to any one who has studied the soil and climate, with the art of cultivating the high lands of Scotland and south of England, the comparison is absurd; and I will venture to say, that if Sussex were cultivated the same as the "high lands of Scotland," instead of returning double the increase, its produce would be greatly diminished. The "Strathern Farmer" very fairly says that he does not pretend to know English farming thoroughly, or enter into its minute details; and we also learn from him that it was at railway speed he saw the defects for which he points out the remedy. He complains that "there is only one-third of the land in crop, if so much," meaning a Corn crop, as if a crop of Hay or Grass for beasts was of little value. True, there are few good meadows in Scotland, and their pasture is generally the most inferior kind, but in the south of England it is the contrary;—meat is more in demand, and we can have Corn transported from Scotland or Ireland more economically than we can have meat or hay for the great metropolis. Good marsh lands in Kent and Essex can be let at 3*l.* per acre, besides paying rates, tithe, and taxes, which may amount to 20*s.* more; and I would ask, Could such land be more profitably employed in growing Corn? There is, no doubt, a great deal in every district that might be improved, but there is nothing in the "Strathern Farmer's" route system particularly new; and if he goes South he will learn more of the best farmers in their own neighbourhood,

they would improve their own farms more than by adopting the customs of a distant county. [This is unquestionably true.] for a very great deal, I find by experience, depends on locality. Scotland in most seasons will grow the heaviest root crops, while England will grow the best Wheat and Barley; Oats will generally, also, be found best in Scotland, because the climate is cooler and more moist; they are too thirsty for the dry lands in Surrey, and it is found better to buy Oats and grow Barley. As to Turnips, if we were to sow them as early as they do in Strathern, on our warm land, they would get rotten before winter; but then we have the advantage of growing a good crop of Turnips after Peas. As to broad hedge-rows and waste land much might be said, but I will only remark at present, that if there were more hedges on the "high lands" of Scotland, they would be found very useful for shelter; but the fact is, it is a hard matter to contend against a high climate, and because hedges grow but very slowly they build there stone dikes (walls) when they can afford it! I may also add that the probability is, while England retains her wealth and game laws, we shall have warrens near the metropolis paying better than Corn fields. I thought Scotchmen knew as well as anybody that the nearer court the more play! As, to ploughs, I doubt whether the Scotch swing-ploughs be fit for all soils and situations; I once thought so, and had one direct from one of the best Perthshire makers, but found it not altogether unexceptionable on Weald clay. The implement described by your correspondent as a "large, clumsy, wooden article," certainly did its work better in certain states of the land. I might here remark that I do not think there is any land in Scotland so difficult to move as the district called the Weald of Kent and Sussex. Mr. Morton says, in his book on Soils, that "the peculiarity of this soil is the minuteness of its parts; the silicious matter being so very fine, and the clayey particles being equally minute, they form a close firm paste, which dries into a substance almost as hard as bricks." Small inclosures and deep ditches are almost essential to get the surface-water off this soil, and old meadows and high hedges are found in practice almost necessary in the cultivation of good Hops. However, these is no doubt as tiles get cheaper, and thorough-draining can be done at less cost, we shall have fewer open ditches; but 6*l.* or 8*l.* for draining an acre of land that is not worth more than 15*s.* to let, is a serious affair even to the landowners, who are sometimes as poor in their way as tenant-farmers. —*J. A. F.*

Game.—We have, in works on Agriculture, a great many useful statements respecting the cost per annum of horses, oxen, sheep, &c. There is, however, one kind of stock reared by us in great quantities, on the annual cost of which per head I can gain no information from any work that I have read. Now, correct knowledge on this point is of the greatest importance; it could be easily obtained at a moderate expense, and is in every way deserving the attention of the Royal Agricultural Society, and of every one feeling an interest in farming pursuits; and I hope and trust that the Society, or some patriotic gentleman, will bring the matter to the test of experiment. This might be done as follows:—Let two adjoining fields, A and B, be selected, and carefully protected from being trespassed upon by any of this stock. Let A be a Wheat-field, autumn-sown; B, a field of Grass or Clover. From each field let half an acre, C C, making together one acre, be fenced with wire lattice; then, immediately after the Wheat is sown, let *one hare* be turned into C C; at harvest, let the crops on C C be accurately weighed, and measured and compared with the other portions of the fields.

If, in consequence of your allowing this letter to appear in your valuable Paper, the above-mentioned or any other experiment is tried, and the cost per head ascertained, you will have conferred incalculable benefit on the farmer.—*A Constant Reader.*

Potato Crop Failure.—It is the generally received opinion among Potato-growers, that a Potato plant should be hoed very deep. Do you not think this has been in a great degree the cause of the failure this season, it being such a dry one? Around this neighbourhood many persons stop till the plant has arrived to a certain height before they hoe them; after this it is general to stay from three to six weeks before they mould them; this, in my opinion, is very much against the growth of Potatoes, for in the first place hoeing them deep (and in many cases when they ought to be moulding them), in dry weather the fibres will get stinted, or will lose most of their youthful vigour; in moulding, I think, great mischief must be done, in a dry season like our last. My plan is, whether it be a dry or wet season, for my Potatoes to be hoed one inch deep, when half of them are above the surface, and moulded when half of them will fairly stand against the moulding, which is a short time after hoeing. I have six different plants this year, at six different places, and not one failure. My moulding ground I dig up in winter, and for common second Potatoes, I dig and plant in the beginning of March, and end about the latter part of April. I have experienced, to my sorrow, the effects of hoeing deep in a dry season; my plants have gone off—and what have remained, the fibres have got stunted in their growth. I have both, like some of your correspondents, plenty of birds, scarcely any Potatoes; by my present plan my Potatoes are not the least injured in their growth; I get abundance of blade, and very fair crops of Potatoes, quite proportionate to their blade.—*Frederic.*

Preservation of Implements.—Amongst the useful information contained in your Paper, I have not, during the six months I have been a reader of it, met with a word on a subject of great importance to the agriculturist: I mean the means which he should adopt to preserve his implements from the decay which is speedily induced by their constant or frequent exposure to sun and rain. I have found paint a poor protection—indeed I am inclined to think that to wood it affords none; for however well my carts, &c., have been painted, exposure to the sun cracks the wood in a thousand places, and opens so many doors for the wet to get in and rot it. My hurdles, when not in use, are carefully stowed away, but I find that before their second winter's work is done, the feet of the larger portion of them are rotten, and the hurdles, in consequence thereof, are comparatively useless. Kyan's solution of corrosive sublimate, Burnett's, of chloride of zinc, and Margary's of sulphate of copper, and other anti-corrosive preparations, have been mentioned to me by their respective advocates as a sure means of preventing rot, and preserving timber; but, having little knowledge of chemistry, I am unable to determine their respective merits, or which of them—taking all things into consideration, especially expense*—I should try. Perhaps, Sir, you will favour me with your opinion on the subject, or request some one of your scientific correspondents to do so, which will greatly oblige—*A Bucks Farmer.*

Stall-feeding.—I find it impossible to read the accounts in the agricultural publications of the day, of the malady which is now proving so destructive to horned cattle, without feeling a desire to contribute towards its abatement. I take the liberty of suggesting whether the immediate adoption of housing and stall-feeding of cattle may not prove a preventive, particularly if steamed food be used. The apparatus necessary for steaming, and its advantages and use, are now well enough understood to be easily set in operation. In 1812, and from thence to 1818, that extensive and excellent agriculturist, the late John Christian Curwen Esq., M.P. of Workington Hall, Cumberland, in communications to the Society for the Encouragement of Arts, Manufacturers and Commerce, demonstrated, and corroborated by the testimony of other agriculturists and dairymen who followed his plans, from having witnessed their success with him, the advantages of stall-feeding and steam-feeding both for cows for dairy purposes and cattle for fattening; with respect to cows, those advantages were, a great improvement in their condition, health, and milking; and their state after becoming dry, when a few weeks' feeding makes them fit for the shambles with very little loss from the first cost; with respect to stock, there were early maturity, diminished risk in rearing, a saving in the cost of feeding, besides the creation of an additional quantity of manure. In 1814 seventeen calves were reared—11 short-horned or Durham, and 6 Ayrshire; not one was lost, nor were they subject to any complaint; in size they were little inferior to those of double their age; so good was their condition that one of the Ayrshire heifers of 18 months old was butchered. The live weight was 55 stone, of 14 lbs. to the stone. The carcass was 31 stone 9 lbs., and the loose fat 2 stone 9 lbs.; it was killed at the meeting of the Workington Society, the carcass esteemed particularly beautiful, and the meat highly approved by the members who saw it. The Durhams were in much better condition, and would have killed 46 stone at least; all costly food was rejected; the produce of two acres, divided between Turnip and Clover, abundantly sufficient to support a beast till 2 years old; the manure created was considerable. Believing the facts here mentioned to be correct, as I find them printed and well authenticated in the volumes of the Society's Transactions, if the suggestion I have ventured to make should prove useful, I shall be much gratified, and only ask the result and details of any trial to be made known through your paper.—*J. S.*

Inorganic Constituents of Plants.—At page 676, you gave an abridged report, from the *Dumfries Courier*, of a lecture delivered by a Professor Johnston, at Castle Douglas; and in a table given in col. *b*, showing the quantity of inorganic matter in 100lbs. of hay, the Professor is represented as stating the amount in Rye-grass hay at 52.8 lbs.; Red Clover, 74.8 lbs; White Clover, 91.1 lb.; and Lucerne, 95.6 lbs. Here, I presume, there is an error in placing the mark denoting the decimals, and that the table really given by the Professor would be for Rye-grass hay, 5.28 lbs.; Red Clover, 7.48 lbs.; White Clover, 9.11 lbs; and Lucerne, 9.56 lbs. Correct tables of this nature are valuable to the intelligent farmer, for he is enabled, by them, to calculate the amount of each inorganic constituent removed from the soil by his crop, and by a corresponding analysis of manures, knows what is most proper to apply to restore his field to its previous fertility. In this lecture the Professor draws the attention of his audience to the disappointment which must follow the trial of any manure which is expected to prove a general specific; and from his remarks on this head, several of your contributors may also profit; as, in many articles I have read, a manure is lauded or condemned, according to the result of a given experiment, without at all taking into account the previously-existing composition of the soil. The difficulty of obtaining a correct analysis of the soil of the different fields of a farm, and the consequent expense, likewise, will effectually deter the majority of farmers from the attempt; and although this knowledge would be valuable, particularly in the improvement of naturally sterile soils, yet, with all fertile soils, the farmer may secure their fertility by restoring annually to the soil, in the form of manure, the same inorganic constituents which he has removed by his crop. It would be a useful plan, as has been suggested by Liebig in his "Chemistry of Agriculture," for the farmer to keep a farm-book, in which, devoting a certain portion to each field, he might systematically note the inorganic ingredients annually removed and restored. Land is honest, and will amply repay any judicious outlay; if a previously fertile soil has become unfruitful, such a book would clearly show it had been unfairly treated.—*G. B.—C.*

Expenses of Horse Labour.—In your last Number a comparison between the value of horses and oxen for farm work is made; but the calculation is based on a stock of horses declining in value. Perhaps many of your readers may not have read the work from which I offer the following extract: It is entitled "A Review of the Corrected Agricultural Survey of Lincolnshire," by Thomas Stone, London, 1800:—

Calculation upon a Stock of Horses declining in value, for a term of 21 years.

Dr.	£	s.	d.	*Cr.*	£	s.	d.
Ten horses, purchased at 15*l.* per horse, at 3, 4, and 5 years old	130	0	0	Value of ten horses at the end of the term of 21 years	150	0	0
Decrease of the value of each horse after 3 years of the term, at 1*l.* per head, for 8 succeeding years, with simple and compound interest on each sum	100	1	10½				
Purchase of one horse every year, for the last 10 years of the term, on account of losses through age and decay, at 15*l.*, with interest, simple and compound, thereon	197	16	0½				
Admitting that, for the last 10 years of the term, a horse is every year purchased, at 4 years old, to supply the place of one dead through age and decay, there will be 10 horses losing 1*l.* per head each, in the 12th year; 9 losing 1*l.* per head each, in the 13th year; 8 losing 1*l.* per head each, in the 14th year; 7 losing 1*l.* per head each, in the 15th year; 6 losing 1*l.* per head each, in the 16th year; 5 losing 1*l.* per head each, in the 17th year; 4 losing 1*l.* per head each, in the 18th year; and 3 losing 1*l.* per head each, for the remaining 3 years; with interest, simple and compound, thereon	79	11	5½	Balance against the farmer	377	9	4½

Agricultural Facts.—A farmer in this neighbourhood put a large Potato, at the proper season of the year, into a heap of mould and ashes left the preceding autumn when the weeds and leaves of the garden had been burnt. It grew with great vigour, and at my request the plant was moulded up and was allowed ample room. In the autumn I took up the plant in the presence of several friends. The diameter of the branches was 8 feet; the number of Potatoes, without counting the very small ones, was 320; they more than filled a bushel basket, and weighed 63 lbs. The largest of the bulbs, 80 in number, were on the south side of the plant.—Some years since

* I observe that the expense per pound of the three articles recommended above, differs very considerably, as does the expense of the brushes to use them; but, perhaps, the expense is according to the efficacy of the article as a preventive of rot and decay.

my servant emptied the brine from a pickled pork tub, undiluted, upon the Grass lawn in my garden in the autumn. The lawn was originally laid with turf, taken from a wet unproductive heath adjoining Mr. Mechi's farm, just now of great celebrity. The consequence was the entire destruction of all appearance of vegetable life for the following summer, the patches looking like brown paper. The second summer a scanty show of feeble blades of Grass came up. The third year the patches were covered with a crowded plant of white Clover! and nothing else; and so vigorous was the growth, that I had them mown four or five times. Fifteen years have elapsed, the lawn has been regularly mown, and the Grasses have now overcome the Clover, but not entirely. The heath or waste from which the turf was taken, never shows a Clover plant, and probably has not for ages. I wish the lord of the manor would let this waste to Mr. Mechi; I think that gentleman would try to develope its productive and hidden mysteries.—*Henry Dixon, Witham.*

Stones on Land.—Pray, sir, may I be allowed to ask, in contradiction to the opinion of some of our would-be-thought farmers here, what utility stones are to the land? A farmer adjoining me will not allow one to be touched, whereas I have sufficient, which I rake off annually and cart away to supply the roads with. My crops are as good as ever—my friend's mostly weeds; in fact, his farm seems, to a casual observer, cropped with both weeds and stones.—*Verax.* [In shallow soils they preserve the moisture which in dry weather would otherwise soon evaporate.]

The Proper Direction of the Traces in Harness.—It is universally admitted that the best way of applying the power of horses is by means of shafts or traces, to carriages. The best position of the traces, or shafts, when a horse is made to exert himself to draw in a carriage, is so well known and understood by those who are daily in the habit of "hanging to," that it needs scarcely be noticed. The trace, when a horse leans forward to draw, should become perpendicular to the collar, and parallel to the plane of the road on which he is moving. In moving up a hill, the trace should become parallel to the plane of ascent. When he is standing at ease, the direction of the trace should be a little upwards; because, when urged to draw, he leans forward, and in doing so, he lowers the forepart of his body, which will tend to bring the trace parallel to the plane when his power is fully applied. If any deviation from the parallel be admitted, it is desirable such deviation should incline upwards rather than downwards. If the direction were downwards below the parallel, the power of the animal would have a tendency to increase the friction, by pulling the wheels into the cavities of the road. After contemplating on these remarks, the following suggestions present themselves:—The radius of the fore-wheels should be less than the height from the road to the point of draught on the shoulder of the animal. The shaft or pole should be hung on a level with the centre of the wheel. The least horse, or rather the horse of lowest stature in a team, ought to be selected for the shafts, and he ought not to be so low as to cause them to incline downwards towards the road. In selecting a team, the tallest horse should be placed first, and the others ought to be so placed as to descend regularly down to the stature of the shaft-horse, in order to preserve a continued ascent in the line of traction. If a regular line of ascent be not preserved, as it will not, by placing a low horse between two tall ones, it is not difficult to show that a portion of their power will be lost in acting against one another, and thus render their united effect not so powerful as it might be by a different and proper arrangement. To individuals acquainted with the elementary principles of Mechanics, these suggestions will appear natural and obvious; but, in practice, it is known that the temper, age, and steadiness of the animal mostly regulate the situation in which we find him placed in the team; and therefore deviations from the rule laid down respecting stature will often be necessary, and perhaps desirable. In teams of perfectly well-trained horses, the rule may be adopted with advantage. [From "Elements of Road Engineering, by a Practical Surveyor."]—*J. B.*

Cheese.—May I ask of you why is Dutch cheese always inferior in flavour, &c., to our English—has a bad sale always, and is at last driven out of the market by the American, the flavour and richness of which is so superior! I fancy the reason to be that their method of soiling their cows in house always, is the main cause of their ill-flavoured cheese and butter. Cut food given to cows never answers so well as the natural pasturing of the animal—so I have found, after several years keeping cows. Soiling cattle for the butcher is one thing, and the soiling of cows for their milk is another; although the animal lives and does well, and is quite healthy—for I have had them 5 years constantly in house.—*Delta.*

Manures.—I perceive in the wholesale prices of manures inserted in the *Agricultural Gazette*, the first article is alum 12*l.* per ton. Pray in what manner is this used as a manure, and to which crop? I have on my farm several lodes or veins of fullers-earth, particularly one in a coppice wood, which is very rich and good in appearance; but on dissolving it, it has too great a proportion of sand or silex I suppose in it, and therefore does not suit the fullers of cloth. Now, if alum be adapted for manure, there being so great a proportion of it in fullers-earth, could not the application of this I have so much of, be of service in agriculture? If so, pray do me the favour to say how it should be applied, and to which crop.—*Delta.* [Fuller's earth does not generally contain alum; see the notice of it in "Jameson's Mineralogy."]

Plantation on Sand-hills.—In an article dated Inverness, and apparently contributed by Mr. Anderson, Secretary to the Farmers' Club in that district, an interesting account is given of the attempt of R. Grant, Esq., of Kilcorth, to clothe his sand-hills with wood, and it seems in a great measure to have succeeded in spite of many obstacles. One great difficulty is fixing the sand, another is the ravages of rabbits, both common to all lands so situated. The best plant to grow is Sea Buckthorn—the botanical name I do not at this moment recollect. It is a native of the North East coast of Britain, and grows plentifully on the sea shore in East Lothian, where many acres of fine Wheat land in that rich district have been saved from being covered with sand, as may be seen near Lord Wemyss's, at Gosford, from whose liberality no doubt plants can be procured. It may also be propagated by seed, which in some seasons is very plentiful, but being once planted the difficulty is keeping it within bounds, as it spreads itself by runners and off-sets—rabbits will not touch it. The Sea-Buckthorn grows quite high enough to shelter young trees, as may be also seen at Gosford.—*M. D. P.*

Magnesia.—In the "Oxford Encyclopædia," article "Agriculture," I read—"By the application of magnesian earth to ground producing Sorrel, both the acid (oxalic) will be neutralised, and the oxalate of potash decomposed, by which means the alkali will be disengaged, and put into a situation to act upon and dissolve the inert vegetable matter in the soil. The salt formed by the combination of the magnesian earth with the oxalic acid will, as well as the vegetable matter dissolved by the alkali, be found to promote vegetation in a very high degree. By the application of alkaline salts to Sorrel, there results a salt fully neutralised, which also highly promotes the growth of more valuable plants and grain." Will you kindly assist me to apply these principles? 1st, What is this magnesian earth, and how am I to obtain and apply it? 2d, I hold a field overrun with Sorrel, which I have just ploughed; am I to harrow out and take off the Sorrel, or leave it to the operation of the magnesian earth? It is a Barley stubble, having previously had Wheat. 3d, The land is a sharp gravel, which has been exhausted by overcropping without manure, and is therefore very poor. I had thought of chalking the field about 4 acres, but I wish to try magnesia, which is said by the above authority to have a better effect, if you will inform me how to proceed.—*Tyro.* [Most limestones contain magnesia; some of those occurring in central England contain it in large quantities. You can use 50 or 60 bushels per acre of such limestone, burnt, and in a caustic state; let it slake under a thickish cover of your soil, and then spread it abroad and plough it under. We do not know how far the views of the writer you quote are correct: he means apparently that the plants should be allowed to live, but this is incompatible with good husbandry. You had better plough it all down together, and any potash salts which it contains, if they come in contact with the magnesia, will be decomposed. Manure well in spring, and grow some root-crop. About guano, see "Notices to Correspondents."]

Tile-draining.—The following observations were made at the Lytham Agricultural Association, by Wilson France, Esq., of Rawcliffe-hall. He said that, so far had he succeeded in making the pipe-tiles by Clayton's machine, that he could sell at 15*s.* per thousand, and might be able afterwards to sell them at 12*s.* Two men and three boys were able to turn out 5490 in one day. He now had at work at Rawcliffe one of Mr. Clayton's machines, and had made a few thousands with it. The length of the tile was 14 inches when burnt, and dried about a foot. Mr. Hammond had formerly used 1¼ inch bore, but now used only an inch bore in all parallel drains; and he says that it is the opinion of all the farmers who have used them in the Weald of Kent, that a bore of an inch is abundantly large. Mr. Langston, of Sarsden, near Chipping Norton, in a Report on the number of pipe-tiles made in ten hours by a 7-inch cylindrical machine, says, that of 2½ inches there were 4686, of 1¾ inch bore 5490, of 1½ inch 7570, of 1 inch bore there were 15,240. The work was done by two men and three boys. Taking into account the expense of labour and coals, if they would be satisfied with tiles of an inch bore, he would make them at 12*s.* per thousand. The weight of 1000 1-inch tiles was 1313 lbs.; that of those 1¼-inch in the bore, 1500 lb. He burnt 22,000 of them in a kiln 12 feet long by 9 feet broad. He had taken 1500 in a one-horse cart; being of so small a bore, no vermin could injure it; neither mole nor water-rat could get into it. This was of great importance.—*Facile.*

Societies.

AGRICULTURAL CHEMISTRY ASSOCIATION.

The Highland Agricultural Society's Seed Wheat Competition taking place on Wednesday last week in Glasgow, a number of gentlemen, members of the Agricultural Chemistry Association, met at a public breakfast, when the following topics were arranged for discussion.—1st, the Smut in Oats; 2d, Why Seed-corn must be changed; 3d, Of the Steeping of Seed-corn. Professor Johnston said, by examination through the microscope, the smut was found to be a species of Fungus, and had obtained the name of Urido segetum. When nearly ripe, if they took a single grain of smut, they found it full of little round puff-balls or sporules, so minute that it required 2800 of them to cover an inch. These minute balls ascended through the plant, and if they looked at a section of a stalk of Barley, they could easily distinguish where they had come up—the tubes of the stalk were filled with black matter that came up through the vessels, affecting, of course, first the straw, and then getting into the ear, where it spread itself all over. After passing through the stalk, the smut fixed itself under the root of the flower, which it rendered barren, and as the grain approached perfection, the puff-balls became ripe and burst, showing black dust of very minute particles, so minute as to require about 1,100,000 of them to lie across a single inch. Such was the smut; it ascended through the circulation of the plant, fixed itself on the flower before it came forth, and finally took the place of the whole ear, and destroyed completely the grain. Now, how was the smut propagated? In the first place it was sown along with the seed. Very often it was so minute that thousands of the particles might attach to a grain of Corn, and yet not be visible to the naked eye; and it would at once be seen how easily these minute particles could be sucked in by the moisture and grow up with the plant. But another way of propagating smut was by the soil itself, so that in many cases where no smut was attached to the seed itself, it might yet be produced from being in the soil. Rye was never attacked by it, and Wheat seldom; Barley was frequently injured; and Oats most frequently of all. The Grasses in the hay-fields, and in the Corn-fields were also attacked and destroyed. Now, this being the case, they would easily understand how sound seed might be sown and yet smut produced. It was considered by some farmers who studied this question, that it would be impossible to extirpate the smut from this cause; but he considered that if all other sources of smut were removed, that cause of it which lay in the soil would not be a very formidable one. Some kinds of Oats were said to be more affected than others. It had been observed in every part of the country where he had been, that new seed was most liable to be attacked, but that the seed sowed the second year was not so much affected. He had seen a field sown with seed purchased in the Dalkeith market, and another field beside it sown with seed of the second year; and the first field was attacked with smut, while the second was free from it. A variety of important questions then came before them, on which information was exceedingly desirable. Had it, for example, been proved that the home seed exhibited less smut than imported seed? How was it that the evil affected so much so important a crop as Oats? Had the soil anything to do with it? Had the seasons any influence in producing it? Some people held that it prevailed only in dry seasons. Then, had the altitude of a place any effect? or was the evil influenced by drainage? Had the severity of the winter anything to do with the matter? Again, did the smut affect the quality of the crops? It was said in England that the wheaten flour was not injured in quality by it; were Oats affected in quality or were they not? Cattle did not like the straw affected with smut; were they from this to draw the inference that it was obnoxious? The great evil to the practical farmer arising from smut was, that it destroyed his crop. In some cases this season one stalk in every ten was affected. This was, of course, a matter of great importance to the farmer; but in addition to that, there arose the question, Was the quality of the grain affected? It was to be observed that before the grain was cut, almost the whole of the smut was blown away; but still there must be a good deal that inevitably adhered, though not visible. Rye and Wheat were naked grains, and therefore the smut was easily carried away; but in Oats and Barley, which were covered with a sheath, it was not so easily blown off, and some of it necessarily adhered. These were all matters on which it was hoped gentlemen present would supply every information in their power. He now came to the question how smut was to be prevented? They were aware that the ordinary method pursued was to make a good selection of seed—to take such seed as from experience was found least likely to be affected. The seed, too, was often washed, and by that means certain portions of the smut were got quit of. The third mode of prevention was by steeping, in which there were two objects in view, only one of which it was necessary to consider at the present moment. One object of steeping was to kill the black dust, so that it would not germinate; but another object was to make the grain grow better. Now, to kill the black dust, or smut, steeping in sulphate of copper, or blue vitriol, was widely adopted; also arsenic, old urine, common salt, lime-water, &c. An important question here arose. For instance, if Wheat was steeped in certain substances, it was found that the smut was prevented, and that the grain grew better and more rapidly; but the question was, Did the extinction of the smut arise from the fact that these solutions killed it, or was the plant made so healthy that the smut could not affect it? Some people believed that insects would not attack trees till they grew weak. Was this the case, and did the same thing occur with regard to crops? With regard to steeps, he might mention as a result of his own observation, that he was in Wigtonshire some time ago, and that at Ballindalloch there was a large field of Oats divided into several parts, and the seed doctored in different ways, some not being doctored at all, other portions being dressed with guano, &c., and others steeped in a composition which he had made up.* On looking at that field it was found that the grain to which nothing had been done was smutted, that which was dressed with

* The following Table is the composition referred to by Professor Johnston:—

Phosphate of soda, Sulphate of magnesia, Nitrate of potash, Common salt, Sal ammoniac, or a Sulphate of ammonia.	One pound of each in 10 gallons of water, to steep 200 lbs. of seed; the moist seed to be dried with gypsum or quick lime.

guano was also omitted, as was likewise a portion where Campbell's steep had been used; but there were only two or three stalks affected with smut in the grain steeped in the composition which he had employed. This was certainly not conclusive, but it was a matter worthy of consideration by farmers.—Mr. Rigby Wason said, when he first began the improvement of Moss-land he found the crops nearly destroyed by smut; by improving the soil, by collecting good seed, and by steeping, he got quit of the smut, and he had no smut for six years until the last, the cause of which he would explain. He submitted the seed to a strong steep of salt, strong enough to float an egg, and never permitted it to remain there less than twelve hours; sometimes he retained it in the steep from 16 to 17 hours, and never found any injury to arise therefrom to the seed. This year he was induced to try Campbell's mixture, wishing to ascertain the benefits derivable from it; he also used common salt, and a portion not steeped at all; when he found that which was not steeped had a few ears of smut, while the other two portions had no smut at all. He did not think Campbell's mixture any better than common salt.—Mr. Alexander, of Southbar, had never experienced so much smut as this year. All his seed Oats were affected; the sandy Oats were, however, worse than the Potato Oats, these being affected one in seven, eight, and ten, up to twenty.—Mr. M'Lintock, farmer, Lochinch, near Pollock, had steeped Oats in guano and water, and had no smut. He used 2½ gallons of water, and 5 lbs. 10 ounces of guano, to 1½ bushel of Oats. He steeped it 72 hours, and dried with ground charcoal. All his Oats were smutty, with the exception of the two lots steeped with guano. They were the sandy Oats.—Prof. Johnston in conclusion said, it appeared that it had not been the custom generally to steep Oats; again, where steeping had been tried by Mr. Wason and Mr. M'Lintock, it had prevented smut; it therefore just came to this, that the practical man in future must steep his Oats, just as he steeped his Wheat, in guano or in salt, or in that steep which he had himself brought before them, and which had proved successful in Wigtonshire. The learned Professor then referred to other important questions relative to the steeping of seeds, &c., but observed that they could not enter upon them on the present occasion, though he trusted other opportunities for doing so would arise.—Mr. M'Lintock said he fully intended to follow out the guano steep. He had tried five or six other steeps, but all had smut but the guano.

FARMERS' CLUBS.

Cardiff.—At the last meeting of this Club, Mr. David, the chairman, made the following remarks on the Deanston, or Frequent Drain System, as compared with Mr. Elkington's system. Mr. Smith, who had devoted so much attention to this system of draining, resided at Deanston, from whence it has taken its name, and, having brought it to such perfection, he may be considered the author of it. He was the manager of a cotton manufactory, which is driven by a stream of water running through this farm, and to secure which he was obliged to take the farm attached to it for a term of years; the extent is from 150 to 200 acres. After completing his cotton mill, his attention was directed to the improvement of the land attached to it, which proved to be a poor tenacious clay of very little value. Mr. Smith, therefore, became a farmer from necessity. He ascertained that his soil was wet from rain-water and not from springs, and he determined upon adopting a system of draining adapted for the occasion, which answered. The chairman's son had visited Mr. Smith, and examined his farm, which he found was now dry, and produced good crops, and he had ascertained that the land had been increased in value from about 15*s.* per acre to from 30*s.* to 40*s.* per acre. Draining was not new even in this part of the country, for he had seen a short time ago some draining tiles at some depth from the surface, in land cut up for a railway, which must have been there many years. In England draining had for some time been extensively practised, and had produced beneficial effects; but it appears their ancestors thought land was only wet from springs, and their attention was directed entirely to that object, cutting the drains in such a manner as would "catch the springs," as it was termed. They did not appear to have considered that the rain which fell had much to do with it, for all their operations were directed to the water from below and not from above. Almost the only authority on draining, which they had about 40 years ago, was Mr. Elkington, who published a work on the subject. He recommended, as the most effectual method of drying low-lands, to sink deep wells upon the system now termed the Artesian system, which was stated to dry up the adjoining springs. He also advised deep drains to be made into the adjoining high land, wherein it was considered that large reservoirs of water had accumulated. These were the principles of draining advocated by Mr. Elkington. Mr. Smith, on the contrary, considered that most of their land was wet from the rain which fell, and not from springs. The quantity of water which falls annually is far greater than is generally imagined. This has been recently proved in the clearest manner by experiments carried on, he believed, in Hertfordshire. It was ascertained by an ingenious contrivance what portion of the rain which fell was required to promote vegetation, and what was the extent of the surplus. The total quantity of rain which fell in the same situation averaged during the last eight years 26¼ inches annually; a body of earth 5 feet deep was so placed as to admit the surplus rain-water which fell on it to run into another rain-gauge, and the result was that out of the 26¼ inches which fell, the average amount which filtered through this body of earth was 11½ inches, and was not required by the vegetation on the surface, which consisted of a thick covering of Grass, the remaining 15¼ inches having proved sufficient for this vegetation and for evaporation. This surplus of 11½ inches must therefore be conveyed off, unless the subsoil is open and sufficiently friable to allow it to pass through it. One inch in depth of water was, he believed, equal to 100 tons per acre. If there is a surplus of 11½ inches to be taken away when the fall is only 26½ inches, the surplus in this country must be far greater with an annual fall exceeding 40 inches. He, the chairman, had kept a register for about 25 years, and he had found that the average depth exceeded 40 inches; it had often exceeded 50 inches in some years, and in assuming 40 inches it would be below the mark. If, therefore, 15¼ is sufficient for vegetation and for evaporation, their surplus would be 34¾ inches to be drained off, but as it is probable that evaporation is greater when the earth is more saturated, perhaps 20 inches would be a fair average, which leaves 20 inches to be drained off from all their clayey soils or those the subsoil of which is impervious to water, otherwise it must stagnate in the land, and prove highly injurious to vegetation. Every inch of water being equal to 100 tons per acre, 20 inches would be 2000 tons. He believed a gallon weighed 10 lbs., consequently this would exceed 7600 hogsheads as the amount of surplus water which fell in this country upon every acre in the course of the year. He therefore thought that they would agree with him that the evil was from above and not from below, and consequently their attention should be directed to the best and most effectual mode of taking off this surplus, in preference to making deep drains at very wide intervals for the purpose of catching the springs. As the rain falls evenly over all the field one large deep drain was not so likely to remove the evil as numerous smaller ones. There are no doubt various situations where land is wet from springs, but his opinion was that by far the largest portion was otherwise, and that nine-tenths of the wet land in this country is so from the subsoil being impervious to water, and will not admit this surplus to pass through it. Again with regard to the last mode of removing this surplus, let them copy nature as closely as they can. In dry friable soils, the apertures below are small and innumerable, and so ought to be their artificial apertures, and placed at some depth from the surface. If they took a section of the land after it is drained with drains 20 feet apart and 27 inches deep, and allowing 7 inches for cultivated land, the drain would be 21 inches below the surface of the subsoil; this would give a fall of only 1 in 6 from the centre of the space between the drains, but if the drains were 31 inches below the subsoil, the fall would be 1 in 4. Again, if the distance between the drains was extended to 30 feet apart, a cross section will show the fall to be only 1 in 9, which is not sufficient to draw off the water through the soil as quickly as it should be; it has also been found that drains at 40 inches deep will drain off more water from the same land than shallow drains at 27 inches, which must arise from the greater fall, but at all events they must not be too far apart. With regard to the expense, he was sorry to say, that it has formed a serious obstacle, for if done properly with tiles and soles the expense has not been much less than 8*l.* per acre; this would be for drains at 18 to 20 feet apart, which is near enough for the wettest land. He had paid more himself in some instances, where he had added about 6 inches of broken stones on the tiles. The tiles were procured from Bridgewater, and the carriage formed a serious item. The invention of pipe-tiles he considered to be a mode of reducing the expense very considerably, which renders soles unnecessary, but they ought to be made on every farm, or very near, to save haulage, and he hoped soon to find that the wettest land might be well drained for about 4*l.* or 5*l.* per acre. Draining should be up and down the land, as it would drain much quicker. If cut, according to the old system, in a slanting direction, the water must travel from the edge of one drain across the whole space into the other; but up and down the slope the water would be divided, and get into the drain in half the distance.—The Rev. James Evans said that he did not think the two systems of draining—viz., the Deanston and Elkington—had been sufficiently contrasted. Elkington had recorded in his work astonishing effects of some drains he had made, and of springs which were tapped. They probably had heard of a coal-pit sunk in Gellygare, which had dried all the springs in the neighbourhood. The effect of frequent drains is very trifling in comparison to these. But he contended that there was no one system of draining applicable to this county. There was in the neighbourhood wherein he resided, and through the vale of this county in general, a large extent of the lias formation, which consisted of alternate beds of clay and rock. He found from some surface and deep drains which he had cut, that the water did not penetrate the first layer of rock; he was, therefore, satisfied that it was quite useless on such soils to make any but surface drains. He had a deep gutter passing through his garden, on the side of which he had holes made for fixing posts; these holes became filled with water, and continued so until absorbed by the atmosphere, although within 4 feet of the drain alluded to. The soil in dry weather cracked extensively.—Mr. Goddard thought that the two systems in question were for totally different objects. He had seen that morning in a field which was kept wet by a spring at its upper side. In that case one drain on Elkington's principle would most effectually dry the field than any number of frequent drains; and in draining it on the Deanston system, the whole field would be intersected by drains, although with the exception of the part where the spring showed itself, the soil was naturally dry. Now he was convinced that dry land would be injured by being drained, as the manure applied to the surface would be washed into the drains.—Mr. Booker observed that no one system of draining could be with success universally adopted, especially in this county, on account of the variety of causes which contributed to the wetness of their soils. The chairman had stated that the quantity of rain which fell in Hertfordshire, on an average of 8 years, was 26½ inches, and that it amounted in this county to 40 inches. Now, this quantity—it appeared from the experiments that had been referred to—was so much greater than was required by cultivated plants, that it became requisite to adopt some means for conveying off the superabundance which fell in every case where the soil and subsoil were not sufficiently porous to admit it to pass freely beyond the roots of plants. The consequence of not attending to this was fatal to a proper system of cultivation, and ruinous to the soil. It was eminently necessary, in determining what system of draining to pursue, to discover the origin of wetness.—Mr. Williams considered the Deanston system applicable to all descriptions of soils. He could not agree that injury would arise from drains being continued even through the driest soils, as in such cases no water would reach them, till the soil was well moistened, if made 30 inches deep. Frequent drains he thought more certain of drying lands affected by springs, at a depth from the surface sufficient for agricultural purposes, than a deep drain on Elkington's system. Part of the Deanston system was to subsoil the land after draining to the depth of 16 or 18 inches at right angles with the drains; this operation materially assisted the draining, as the water at once sunk that depth from the surface, and was gradually admitted into the drains through cracks or worm-bores.—After a desultory conversation among other members, it was determined to resume the subject at a future meeting.

Miscellaneous.

Report of the Thorough-Draining executed on the Estate of Edward Lucas, Esq., Castle Shane, Monaghan, by Fitzherbert Filgate, Esq.—The next field drained was done at the same rates, exactly as the preceding; and the observations made with respect to the one apply to the other, excepting that in this case the main drain was cut for 3½*d.* per perch.

No. of acres in field.	No. of perches of small drains.	Price per perch.	No. of perches of main drains.	Price per perch.	Total cost of field.	Cost per acre.
A. R. P.		*s. d.*		*s. d.*	£ *s. d.*	£ *s. d.*
5 1 2	949⅔	0 4½	6⅔	6 3½	19 9 8	3 14 0

The water from these fields is carried away by the flagged sewer already mentioned. The next field, containing 2A. 2R. 13P., is part of a field adjoining one of the approaches to the house, which was exceedingly wet, and covered with rushes. It was necessary to make a great length of main drains to carry off the water to the stream at the bottom of the field, which makes the expense much more considerable than it would otherwise have been; but if the remainder of the field should be at any future time taken in hand, this length of main drain would become available for it. The prices paid were, cutting, filling, breaking stones, &c., 3½*d.* per perch for small, and 7½*d.* for main drains. The stones were quarried in the demesne for 1½½*d.* per perch, and drawn to the field by the farm-horses. The money paid was:—

No. of acres in field.	No. of perches of small drains.	Price per perch.	No. of perches of main drains.	Price per perch.	Total cost of field.	Cost per acre.
A. R. P.		*s. d.*		*s. d.*	£ *s. d.*	£ *s. d.*
2 2 13	448⅘	0 4½	110⅘	0 7½	11 18 5	4 12 4

Parts of two fields, lying near a stream, containing 1A. 3R. 11P., were drained: the stones laid down by the farm-horses. As the ground was very soft, the main drains were cut at the same rate of small ones, 3½*d.* per perch. The outlay was as follows:—

No. of acres in field	No. of perches of small drains.	Price per perch.	No. of perches of main drains.	Price per perch.	Total cost of field.	Cost per acre.
A. R. P.		*s. d.*			£ *s. d.*	£ *s. d.*
1 3 11	393	0 3½	—	—	3 16 11	2 2 6

We finish with the field containing 5A. 1R. 2P. The soil is a rich heavy *loam*, of great depth; so deep, that in many places at the bottom of the drains we had not come to the subsoil. The price paid for cutting and filling drains and breaking stones was the same as before, 3½*d.* per perch; the stones were bought at 3*d.* per ton, 210 tons being used. They were carted more than one Irish mile, in carts hired at 2*s.* 6*d.* per day for cart, man, and horse. The cost of the stones when laid down in the field was 4½*d.* per perch. This and a preceding field were the only cases in which, under peculiar circumstances, the stones were attempted to be provided otherwise than by contract, and, as appears from the table, with an increased expense of from 25*s.* to 30*s.* per acre. The main drains cost for cutting, &c., at the rate of 3½*d.* and 5*d.* per perch, according as they required to be cut unusually deep or not.

No. of acres in field.	No. of perches of small drains.	Price per perch.	No. of perches of main drains.	Price per perch.	Total cost of field.	Cost per acre.
A. R. P.		*s. d.*		*s. d.*	£ *s. d.*	£ *s. d.*
5 1 2	966	0 7½	{ 82 / 36	0 9½ / 0 6 }	29 1 9	5 10 6

It may be observed, generally, that the circumstances attending the execution of the several works have been more unfavourable than might be calculated on, if compared with other localities, all the stones used having been quarried, with the slight exceptions mentioned. The nature of the country being hilly, has in many cases made it necessary to provide for the discharge of water, unconnected with that to be voided from the field drains; for which reason the main drains have been of larger dimensions than would otherwise be required, while the smallness of the inclosures has also occasioned additional outlay. The great expense being the drawing and procuring of stones, the cost will depend chiefly on the difficulty or facility with which they may be provided. In some cases when the drawing of the stones was performed by the farm-horses, the value of their labour and that of the men employed must be added to the amount stated. It would not be possible to name the exact sum, charging the man and horse at 3*s.* per day, or any other sum, as the stones were laid down at intervals as suited our convenience. There is in all farms where there is not much summer fallow, a period at that season, during which all the horses are not employed at the ordinary routine work of the farm; if this opportunity be taken, being the best season for laying down stones in the fields to be drained, no expense is entailed by their employment. A calculation may, however, be made by adopting the prices of any one, or taking the average of those fields, where the stones were provided by contract, deducting the amount paid for quarrying for those fields to which the stones were drawn by the farm-horses. I have thought it better, however, to state all the cases as they actually occurred, rather than make any speculative return. I subjoin a tabular statement of the whole—

No.	No. of Acres in field.	No. of perches of small drains.	Price per perch.	No. of perches of main drains.	Price per perch.	Total cost of field.	Cost per acre.
	a. r. p.		s. d.		s. d.	£ s. d.	£ s. d.

				36	0 8		
	57 3 13	9895½	—	969½	—	269 11 4	—

In addition to the above, there have been 3528 perches of small drains, and 302 perches of main drains made on Mr. Lucas's estate, in the years 1842 and 1843, for which the tenants were allowed 1-½*d.* per perch for the former, and 2½*d.* per perch for the latter. The drains were all finished as before described, and made eighteen feet apart. There being 186 perches to the acre, exclusive of main drains, when the drains are eighteen feet apart, it will appear there have been nineteen acres drained by tenants. —*Signed, F. Filgate, for E. Lucas, Esq.* [*From the Report of Agricultural Imp. Society of Ireland.*]

Notices to Correspondents.

Agricultural Gazette.—*Ed. M.*—Thank you for your suggestion; it would moreover be difficult to classify such mingled matter as we receive. We must depend on our Index at the end of the year for a classification of the contents of our volume.

Allotment System.—*L. C.*—We have received your papers, and are much obliged.

Alum.—*Delta.*—We are not aware that it is an ingredient, to any extent, of fuller's earth. The properties of this substance as a cleanser of oily cloths depends on the peculiar condition of the alumina it contains. We never saw alum used as a manure, and cannot believe that it can be economically applied; for any of its ingredients may be had more cheaply in other substances. Thanks for your offer about Potato-culture, which we gladly accept.

Books.—*A Watchman.*—Hillyard's "Practical Farmer and Grazier."

Campbell's Breeds.—*W. C. S.*—Upon the whole, the experience of farmers and others this year, so far as has been reported to us, has *not* been favourable to their use. How far this is a consequence of the season we are unable to say. We shall have a few remarks to make on this subject shortly.

Chalkings, &c.—*Landlord.*—Chalk may be most beneficially applied to clay soils; and, even in the small quantities to which its use on the dunghills, in the manner you propose, will amount, it will probably do good. It is a good plan to have farm-yards with slightly basin-shaped and impervious bottoms; a tank considerably larger than what you name, should be dug in the centre, and by means of a pump you can spread its contents over manure heaps when fermenting, and just before carrying to the field. See Hannam on "Waste Manures." One of the most practical works on Drainage is a tract by Mr. Smith, of Deanston, on "Thorough Draining." We give our farm horses Carrots, Oats, and Hay. Will Carrots do for carriage horses? If so, they will help to clear out your stock of hay.

Coal-ashes and Sea-sand.—*J. B. T.*—Asks for the results of experience in the use of these two substances.

Cows.—*M. D.*—The best root to give them, so as to make them yield rich milk, is the Parsnip. Oil cake is the best food you can give them in addition to this and hay; and in small quantity, say 2 or 3 lbs. per day, it might be profitably used: him with 25 or 30 lbs. of Parsnips and hay *ad. lib.* would be as good feeding as a dairyman could desire.—*Sidcup.*—The case is uncommon, but now and then occurs. We believe that it arises from the wants of nature not having been satisfied, through the usual signs of this want not having been observed.—*W. C. S.*

Disease in Pigs.—*A. E.*—The loss of the tail in pigs is generally confined to those of the pure Chinese variety, or pigs in which this breed strongly prevails. It arises from imperfect development and want of vigour in these appendages, which is in keeping with the thinness of the skin and fine hair peculiar to this breed. With regard to the case of palsy, try as an experiment, quarter of a grain of strychnia, in addition to the medicine previously given, once a day. *W. C. S.*

Diseased Wheat.—*W. Jones.*—The disease of which your ear exhibits a specimen, is called Bunt, Smut-balls, or Pepper-brand. Its cause is a parasitic fungus, the seeds of whose action is similar to that of the fungus which produces smut. See report of Ag. Chem. Assoc., and Professor Henslow's report on the Diseases of Wheat, second vol. of the "Agricultural Society's Journal." Your remedy is theoretically to cleanse the seed; and this is done by soaking it in a strong solution of salt, and afterwards drying with lime.—*Breadsley.*—Your specimen contains what are called Pepper-corn grains. See Professor Henslow's Paper on Diseases of Wheat, in the second vol. of the "Agricultural Society's Journal." If you moisten a grain for half a minute in your mouth, and cut it in halves on a strip of glass in a drop of water, a very low power of the microscope will suffice to show the white substance it contains to be a mass of the *vibrio tritici*—a curious eel-shaped animalcule, which will gradually revive and twist about.

Farmers' Clubs.—*A Subscriber* asks What are the nearest Farmers' Clubs to Fulham and Putney?

Fibrilay as Manure.—*A. H.*—The results of this experiment were certainly (looking at its composition) not the consequence of the manure employed. The experiment was too small in extent to inspire confidence. In such limited trials co-existent circumstances are frequently erroneously understood as standing to one another in the relation of cause and effect. Perhaps it might have been as well not to have published this experiment; but it is impossible that one ignorant of the circumstances in which the various experiments which are reported to him were tried, can be qualified to select or reject; he must hope, in the number of facts he publishes, that opposite errors will neutralise one another.

Guano.—*Tyro.*—You had better plough and sow Wheat now, and sow 3 cwt. mixed with its weight of earth, broadcast, over the young plants in April, and harrow it in.

Harvesting Carrots.—*H. S.*—See Leaders of next and last week.

Inundation.—*M. D. P.*—Your Grass-land that has been inundated from the sea, might, perhaps, be benefited by a coating of lime. In this we do not speak from experience; perhaps some of our readers can help you.

Plough, &c.—*Q. Q.*—Your safest plan is to employ the best constructed implement already used in your neighbourhood. The Scotch swing-plough, in the hands of a man accustomed to swing-ploughs, is a most efficient implement, but it will not do to put it into the hands of any wheel plough man. Etheridge's tile machines are excellent, but there are now so many copyists from him, that we cannot presume to select from them. It is probably your interest to use foreign oil cake; it may be crushed by the common cake-crusher, and so mixed with Barley-meal. How would it answer your purpose to feed your cattle on Mr. Warner's pudding? See former papers on the subject by Mr. Sproule.

Potatoes.—*Woodstock.*—When these have been left in the ground for seed, it has been done simply by not disturbing the drills in which they were grown. Harvest the tubers in February or March, instead of in October, and use them as seed in the usual manner, at the usual time.

Samples of Oats.—*G. M.*—Your samples are so nearly alike in appearance that we cannot judge between such small quantities. Weigh *a bushel* of each, and let that be considered best which weighs heaviest.

Scab in Sheep.—*R. L.*—Amongst a variety of applications which have been employed for this disease (see Spooner's "Treatise on Sheep"), the following will be found as efficacious as most of them, and extremely safe:—Take sulphur powdered 1 lb., oil of tar ½ lb, palm oil 2 lbs.; the two former ingredients to be gradually mixed, and the latter then rubbed down with them. To be well rubbed in to every affected and suspected part, and repeated every three or four days till the disease disappears. With regard to *prevention*, all we can say is—avoid contagion and poverty; watch narrowly, and separate the diseased from the sound sheep as soon as the least itching is exhibited.—*W. C. S.*

Sea Mud.—*M. D. P.* asks How he is to bring land, newly inclosed from the sea, into cultivation? We think he had better give it a summer fallow, ploughing it deeply into narrowish ridges, manuring it well with half-rotten dung; he may sow Wheat in the autumn. We should be glad of the experience of our readers on this subject.

The Barbadran.—*Subscriber.*—Your articles are skilfully compiled, and seem calculated to do good. We think they deserve publication.

To Readers.—*A Constant Reader* asks where the following quotation originated?—"The man who makes two blades of Grass to grow where one only grew is a benefactor to his country."

Wheat.—*T. S.*—Guano is the best substitute for farm manure; you had better apply 3 cwt. in April, mixed with an equal quantity of dry earth. Sow it broadcast over the young plants, and harrow in. Do this in showery weather if you can.—*Broadchalk.*—We prefer sowing our Wheat when the soil is wet, i. e. when it is so damp that a horse will leave a good deep footstep in it. Our soil is sandy; on clay soils it may not be advisable to sow so wet as this. When we have not so much matter on hand as at present, we may perhaps give information on the analysis of soils; meanwhile we may direct you to a chapter in "Johnston's Lectures on Agricultural Chemistry," on the Analysis of Soils, and to a work by Mr. Parnell on the general subject of Chemical Analysis.

*** As usual, many communications have been received too late.

Markets.

SMITHFIELD, Monday, Oct. 21.—Per stone of 8 lbs.

Best Scots, Herefords, &c.	3	6	to	3	8	Best Downs & Half-breds	3 6 to 3 8
Best Short Horns	3	6		3	10	Best Long-woods	3 6 4 0
Second quality Beasts	3	8		3	4	Ewes and second quality	3 4 3 8
Calves	3	4		4	4	Pigs	3 4 4 4

Beasts, 3313; sheep, 20,310; Calves, 297; Pigs, 348.

Although we have an increased supply of Beasts, the demand is fully adequate; indeed the best qualities in many instances are making more money; several of the first-rate Beasts, &c., realised to 3*d*, and Shorthorns as per 8 lbs, yet these are quite the extreme prices and cannot be quoted as averages; inferior Beasts are more readily disposed of, but they still make very little money; very few remain unsold. The quantity of Sheep being not quite so large to-day, there is a brisk trade at an advance of about 2*d* per 8 lbs on the best qualities. Calves are less in number, yet the trade is not much improved—it must be very superior quality to make 4*s* 4*d* per 8 lbs. Pork trade is steady.

Friday, Oct. 25.

Our supply of Beef to day is rather larger; there is not much business doing, and it is difficult to maintain Monday's quotations, although it is 2*s* per 8 lbs for the best qualities, which make about 4*s* per 8 lbs; middling Beasts at 3*s* 8*d* to 3*s* 10*d*. The late brisk sale in the Scotch trade has caused rather a larger supply to day; the prices are a little lower than on Monday; best Downs, Half-bloods, Wethers and Long-woods rather more than 3*s* 6*d*; Ewes are not very saleable they make from 3*s* to 3*s* 6*d*. Veal trade is very heavy, the best Calves cannot be quoted at more than 4*s*, and middling quality as low as 3*s* 6*d*. Pork trade is worse; it has been sold at very low prices in the dead market this week.

Beasts, 200; Sheep, 4600; Calves, 209; Pigs, 270.

E. Weir, Smithfield.

POTATOES.—Southwark Waterside, Oct. 21.

Trade is reviving in this Market at present that requires attention; every description of goods is going off briskly at the following quotations. The supplies at the close of the week were considerable, and it is to be feared that they will occasion a further depression in our prices.

York Reds	75	80	Kidneys	90	95	
Do. Whites	85	90	Wisbeach Giants	80	85	
Early Purples	70	—	Do. Reds	90	95	
Early Dwarfs	75	—	Do. Whites	90	95	
Cornwalls	85	90	Gosbeary Reds	75	80	
Fluke	85	90	Do. Whites	75	80	
Do. White	85	90	Private Regents	90	95	

COVENT GARDEN, Oct. 23.—There has been little variation in the prices of most articles during the past week: the market has been well supplied, but trade continues dull. Pine-apples are rather on the rise; among them there are many handsome fruit. Grapes are also slightly advanced in price. Melons are becoming very scarce. The supply of Pears and Apples is quite sufficient for the demand; of the former the best sorts at present in the market are—Louise Bonne (of Jersey), Marie Louise, Beurré Diel, and Gansel's Bergamot; among Apples we noticed some fine specimens of Blenheim Orange. Walnuts, Filberts, and Nuts, are tolerably plentiful, and are good in quality; Cob-nuts are selling at from 90*s.* to 100*s.* per 100 lbs. A few Plums are yet to be met with, but they are becoming scarce. Oranges of every kind are now nearly, if not quite over, and Cucumbers are also getting scarce. Among vegetables the supply of Cauliflowers is decreasing; but Brussels sprouts, Savoys, and other winter greens are becoming more plentiful. French Beans are nearly over. Onions are good, and fetch nearly the same prices as last week. Some fine specimens of Celery, clean and well blanched, are in the market. Turnips and Carrots are excellent in quality, and are quite sufficient for the demand. Endive and Lettuces are well supplied. Sallads and Scorzonera are selling at nearly the same prices as mentioned in our last Report. Radishes bring, also, nearly the same prices as last week. Cut Flowers chiefly consist of Rondeletia speciosa, Cupressus purpureum, Pentas carnea, Cactus Jenkinsonii, Gloxinias, Heaths, Chrysanthemums, Lupines, Scarlet Pelargoniums, Mignonette, Fuchsias, Camellias, and Roses.

FRUITS.

Pine Apple, per lb., 4*s* to 6*s* 6*d*	Chestnuts, per peck, 3*s* to 4*s*
Grapes, Hothouse, p. lb., 1*s* 6*d* to 3*s*	Walnuts, per bushel, 8*s* to 9*s*
— Spanish, per lb., 1*s* to 2*s* 6*d*	— — shelled, 12*s* to 16*s*
— Portugal, per lb., 1*s* to 2*s*	Barberries, per half-sv., 2*s* 6*d* to 3*s* 6*d*
Melons, each, 1*s* to 2*s*	Oranges, bitter, per 100, 6*s* to 12*s*
Plums, per half-sieve, 2*s* 6*d* to 3*s*	Lemons, per dozen, 1*s* to 2*s*
— Imperatrice, per punnet, 1*s* 6*d*	— per 100, 6*s* to 16*s*
— Coe's Gold. Drop, pun., 1*s* to 1*s* 6*d*	Almonds, per peck, 6*s*
Damsons, per half sieve, 1*s* 6*d* to 2*s* 6*d*	Sweet Almonds, per lb., 2*s* 6*d*
Apples, Dess., per bush., 2*s* 6*d* to 3*s*	Cob Nuts, per 100 lbs., 80*s* to 100*s*
— Kitchen, 2*s* to 4*s*	Nuts, Barcelona, 24*s*
Pears, Dess., per hf.-sv., 3*s* to 3*s*	— Brazil, 16*s*
Quinces, per half-sieve, 1*s* 6*d* to 2*s*	— Cob, 12*s*
Filberts, per 100 lbs., 70*s* to 80*s*	

VEGETABLES.

Cabbages, per dozen, 6*d* to 1*s* 3*d*	Leeks, per doz., 1*s* 6*d* to 2*s* 6*d*
Cauliflowers, per doz., 1*s* 6*d* to 4*s*	Garlic, per lb., 4*d* to 6*d*
Broccoli, per bundle, 6*d* to 1*s*	Onions, per bunch, 3*d* to 6*d*
Brussels Sprouts, hf.-sv., 1*s* 6*d* to 2*s*	— large, per bushel, 3*s* to 4*s*
Sorrel, per hf.-sieve, 6*d* to 9*d*	— Spanish, per doz., 3*s* to 4*s*
Artichokes, per doz., 2*s* to 4*s*	Shallots, per lb., 4*d* to 6*d*
— Jerusal., p. hf.-sv., 1*s* 6*d* to 1*s* 6*d*	Tomatoes, per half-sv., 2*s* 6*d* to 4*s* 6*d*
French Beans, hf.-sv., 3*s* to 3*s*	Capsicums, Ripe, per 100, 4*s* to 6*s*
Scar. Runners, per hf.-sv., 1*s* to 2*s*	— Green, per 100, 1*s* to 2*s*
Potatoes, per ton, 80*s* to 90*s*	Radishes, per doz., 6*d* to 1*s*
— new, 2*s* 6*d* to 4*s*	Lettuce, per score, 6*d* to 1*s* 6*d*
— bushel, 1*s* 6*d* to 2*s* 6*d*	Celery, White, per bunch, 3*d* to 1*s* 3*d*
— Kidney, per bush., 3*s* to 4*s*	— Red, per bunch, 1*s* to 1*s* 6*d*
Turnips, per doz. bch., 1*s* 6*d* to 2*s* 6*d*	Endive, per score, 1*s* to 1*s* 6*d*
Red Beet, per doz., 3*d* to 1*s* 6*d*	Mushrooms, per pottle, 10*d* to 1*s* 6*d*
Carrots, per doz. bchs., 2*s* to 3*s*	Small Salads, per punnet, 3*d* to 6*d*
Basil, per bunch, 3*d* to 6*d*	Watercress, p. 12 sm. bun., 3*d* to 6*d*
Horse-Radish, per bundle, 3*s* to 6*s*	Parsley, per doz. bunches, 1*s* to 2*s*
Savory, per bunch, 3*d* to 6*d*	— Roots, per bundle, 3*d* to 1*s*
Cucumbers, Frame, each, 3*d* to 6*d*	Tarragon, Green, per bunch, 3*d* to 6*d*
— Ridge, dou., 3*d* to 3*s* 6*d*	Green Mint, per bunch, 3*d* to 6*d*
Spinach, per sieve, 1*s* 6*d* to 2*s*	Marjoram, per bunch, 3*d* to 6*d*
Scorzonera, per bunch, 1*s* to 1*s* 6*d*	Chervil, per punnet, 3*d* to 6*d*
Salsafy, per bunch, 1*s* to 1*s* 6*d*	Chilis, per 100, 1*s* to 2*s*

WOOL.—British, Friday, Oct. 25.

South-down Fleeces	1 0	1 1	James Fenner, Wool Broker.	

MARK-LANE, Monday, Oct. 21.

The supply of Wheat from the adjoining counties was small this morning, which enabled Factors to realise the same prices as last week. The demand for Foreign continues limited, and its value unaltered.—Malting Barley finds ready buyers at an advance of 1*s.* per qr. above the quotations of this day se'nnight; Grinding remains without alteration.—Beans sell freely, and are 1*s.* to 2*s.* higher.—Peas are also 1*s.* dearer.—In Oats there has been a good business doing, at fully 5*d.* per qr. over the rates of last week.

British, per Imperial Quarter.	s.	s.		s.	s.

Friday, Oct. 25.

We are without any fresh arrivals of Wheat for this morning's market, and its value consequently remains unaltered. In Foreign, business is limited, but Monday's prices are fully maintained.—Fine Barley fully supports our quotations, but grinding qualities sell slowly; there is a good arrival from abroad, a large proportion of which continues to come out of condition.—Beans and Peas are scarce, and inquired after.—We have a good supply of Oats, including several cargoes from abroad; holders are firm at Monday's prices, but the extent of business doing is small.

ARRIVALS THIS WEEK.

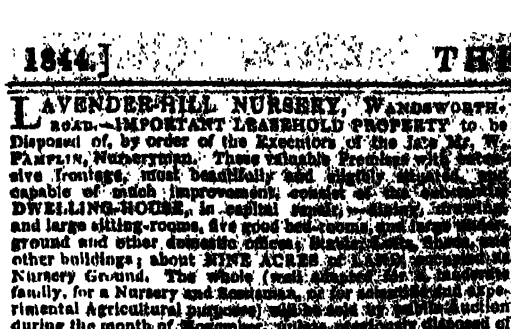
LAVENDER-HILL NURSERY, WANDSWORTH-ROAD.—IMPORTANT LEASEHOLD PROPERTY to be Disposed of, by order of the Executors of the late Mr. W. FAMPLIN, Nurseryman. These valuable Premises, with extensive Frontage, must beautifully laid, highly cultivated, and capable of much improvement, consist of the commodious DWELLING-HOUSE, in capital repair;—dining, drawing, and large sitting-rooms, five good bed-rooms, and large cellarage; ground and other domestic offices; Stabling, Sheds, and other buildings; about NINE ACRES of LAND, principally as Nursery Ground. The whole (well adapted for the occupation of a family, for a Nursery and Seedsman, or for extensive and experimental Agricultural purposes) will be sold by Public Auction during the month of November, unless previously disposed of by private Contract.

For particulars apply to Mr. W. J. LEAN, Clapham-Common, or to Mr. W. FAMPLIN, Bookseller, &c. Fifth-street, Soho.

TO FARMERS.

TO BE LET on LEASE, and entered upon immediately, Two good Farm Houses, with FARMS, containing about 200 acres—in a most highly productive Hop Plantation, 61 acres Meadow, and the remainder Arable. A convenient Farm-house stands on the Premises, as well as Oast-house and other Farm buildings. The Farm is situated near a Terminus, and the journey to London is accomplished by Railway in 1 hour and 47 minutes; it is also near a good market-town.—For further particulars apply to Mr. ARTHUR SMITH, 6, John-street, Bedford-row.

HOT-WATER APPARATUS FOR HEATING HORTICULTURAL BUILDINGS, DWELLING-HOUSES, CHURCHES, and MANUFACTORIES, upon improved principles, and at very moderate charges, erected by DANIEL and EDWARD BAILEY, BIA, HOLBORN.



D. and E. BAILEY having devoted much time to the consideration of this subject, and their much experience in the erection of apparatus for the above-mentioned purposes, have, by improvements suggested in their practice, rendered their mode of heating not only very efficient, but very simple, and have combined durability in the apparatus with economy in the charge. They have erected apparatus in England, Scotland, and Ireland, for many noblemen and gentlemen, and have had the honour to be employed by the Horticultural Society of London, in executing the works of their splendid Conservatory, lately erected at Chiswick.

D. and E. BAILEY also construct in metal all descriptions of *Horticultural* Building and Garden, and invite noblemen, gentlemen, and the public to an inspection of their various drawings and models, at 378, Holborn, where they have the opportunity of exhibiting, amongst other metal works, an extremely complete and convenient Kitchen apparatus, or range, adapted for the continued supply of hot water, and an arrangement of tin oven more complete than has hitherto been brought before the public.

D. and E. BAILEY were the first to introduce metallic curvilinear-houses to horticulturists, and can refer to the Conservatory attached to the Pantheon as one of their works, besides many others in this country and on the Continent.

D. and E. BAILEY have prepared a quantity of the Galvanic Plant Protectors, which are now ready for immediate delivery; they beg to introduce to public notice a new Trough Pipe, for Orchidaceous or other Houses where vapour is constantly, or at intervals required, and which may be seen at their Manufactory.

COTTAM AND HALLEN, ENGINEERS, IRON-FOUNDERS, &c., Nos. 2 & 3, WINSLEY-STREET, OXFORD-STREET, LONDON, and 21, CORNWALL-ROAD, LAMBETH.

HOTHOUSES & CONSERVATORIES, &c., made upon the most improved principle, either of iron or of iron and wood combined, which can be fixed complete in any part of the Kingdom, at very low prices.

HOT-WATER APPARATUS for heating Hothouses, Conservatories, and Greenhouses; Churches, Public or Private Buildings, &c., with COTTAM'S PATENT or ROGERS'S BOILERS. After 18 years' experience, and having fixed upwards of 2000 Apparatus for the above-mentioned purposes, and by various improvements which they have made during that time, C. and H. can with confidence undertake the erection of similar Apparatus upon the most extensive scale.

Materials may be had for those who wish to fix their own Apparatus.

THE TANK SYSTEM on an improved principle, that will heat the house at the same time, without pipes.

IRON HURDLES, best Wire for Strained Fencing, Ornamental Iron and Wire-work, Garden Chairs, &c., &c., and every description of Implement for AGRICULTURAL and HORTICULTURAL PURPOSES.

Show Rooms at their Manufactory, 2, Winsley-street, Oxford-street, where a large assortment of the above can be seen.

STEPHENSON AND CO., 61, Gracechurch-street, London, and 17, New Park-street, Southwark, Inventors and Manufacturers of the Improved CONICAL and DOUBLE CYLINDRICAL BOILERS, respectfully solicit the attention of scientific Horticulturists to their much approved method of applying the Tank system to Stoves, Propagating Houses, &c. by which atmospheric heat as well as bottom-heat is secured to any required degree without the aid of pipes or flues. S. & C. have also to state that at the request of numerous friends they are now making their Rollers of Iron as well as Copper, by which the cost is reduced. These Rollers, which are now so well known, require no further description, but to those who have not seen them in operation, circulars will be forwarded as well as references to the highest authority; or they may be seen at most of the principal Seedsmen's and principal Nurseries throughout the Kingdom.

S. & Co. beg to inform the Trade that their Manufactory in New Park-st., every article required in the construction of Horticultural buildings, as well as the Apparatus, may be obtained upon the most advantageous terms.

Conservatories, &c., of Iron of the most approved and elegant ornamental designs, Balconies, Verandahs, Rustic Garden Fences, Wire Work, &c. &c.

GUANO (GENUINE PERUVIAN) ON SALE, BY THE ONLY LICENSED CONSIGNEES, ANTONY GIBBS AND SONS, LIMITED.

WM. J. MYERS sole Agent.

And by their Agents,

COTESWORTH, POWELL, AND MANNING, LONDON.

GIBBS, BRIGHT, & CO., LIVERPOOL AND MANCHESTER.

47, Lime-street, Oct. 26, 1844.

WIRE-WORK, HOT-WATER APPARATUS, GREEN-HOUSES, &c.

ST. THOMAS-BAKER, MANOR-HOUSE, MANOR-PLACE, KING'S-ROAD, CHELSEA, Manufacturer of PATENT WIRE-FENCE, to resist Cattle, Poultry, Game, Rabbit-proof. WIRE-WORK in Trellis, Screens for Vineries, Fruit-trees, Flower Stands, Fire-screens, &c. HORTICULTURAL BUILDINGS, Green and Hothouses, Conservatories, &c. The same heated by HOT-WATER APPARATUS, on improved and economical principles.

Parties waited on in Town or Country, and Drawings and Estimates free. Work for the Trade as usual.

Ward's Cases, or Domestic Greenhouses.

GUANO for SALE, in Bags of 1 cwt. each, just landed, with a succession of cargoes to arrive. Twenty years' experience has unquestionably proved that genuine Guano is the simplest, cheapest, and best Manure within the reach of the Agriculturist. The only reasonable anxiety which now remains is to procure the Guano unadulterated, and to obtain such practical directions for using the Manure as shall fully develop its productive powers. To secure to buyers these indispensable requisites, with each purchase will be given a warranted chemical analysis of quality, and also a copy of the recently-published Pamphlet, "Practical Instructions for using Guano as a Manure, illustrated by Practical Results."

Large parcels will be delivered direct from the ship or waterside premises; smaller quantities may be had at the warehouse, 20 and 21, Billiter-street, or delivered within any reasonable distance in a trifling additional cost. Apply to JAMES CLARK, 20, Billiter-street.

WHEAT-SOWING.

GUANO; Genuine Peruvian, Bolivian, and Ichaboe, on Sale; also Potter's Guano, Gypsum, Sulphuric Acid, Sulphates of Iron and Copper, and all other manures. Synopsis of prices, and mode of use, on application, &c.—Apply to MARK FURGUSELL, 40, Upper Thames-street.

GUANO, IMPORTED BY WILSON AND VAUSE, HULL,

Who have now on Sale a selected Cargo of superior quality, per "Britannia," direct from Ichaboe, with a succession of Cargoes to arrive. Samples, with instructions for use may be had at 19, Bowl Alley Lane.

MR. LAWES' MANURES.—Mixture for Wheat, 7l. per ton; Super-phosphate of Lime, 7l. per ton. To be had at the Factory, Deptford Creek, near London.

Super-phosphate of Lime, in a concentrated form, may also be procured at Messrs. WARNER'S, 26, Cornhill, in 7lb. packets, price 1s.

WHEAT-SOWING.

FREDERICK BRAIN begs to call the attention of the Agricultural world to his GUANO MANURE, prepared expressly for Wheat crops: it abounds in all the ingredients that are necessary for a good grain crop. He particularly solicits persons who found the Foreign Guano a failure last season to give his a trial, it being much more powerful, and free from adulteration, so justly complained of in the Foreign by Agriculturists, as well as by all the leading Agricultural Journals.

Testimonial to Brain's Guano Manure.—"5 A, Hawley Road, Kentish Town, London, Aug. 15, 1844.—This is to certify that we have subjected Brain's Guano to a most patient and rigorous analysis, and find it contains all the necessary constituents of a good manure, and is well calculated to give fertility to a soil which is either naturally barren, or has been exhausted by over-cropping, by supplying the land with those substances which are absolutely requisite to a healthy vegetation; (it is not adulterated, and can always be depended on being of uniform composition.)—(Signed) JOHN MITCHELL and FREDERICK FIELD, Analytical Chemists, late of the Royal Polytechnic Institution, London."

Also, BRAIN'S highly concentrated LIQUID GUANO, for Grass Lands, Gardens, Shrubberies, Hothouses, and Conservatories, price 1s. 6d. per quart bottle, with full directions for use, (enough for 60 gallons of Liquid Manure), to be had of most respectable Florists, Seedsmen, and Chemists in town and country.

Works, Thomas-st., Duke-st., Stamford-st., Blackfriars-road.

IMPORTANT TO AGRICULTURISTS, &c.

ANALYSES of SOILS, MANURES, and all AGRICULTURAL PRODUCTS, are conducted by Messrs. MITCHELL and FIELD (late Mr. Mitchell), Analytical Chemists, with the view of ascertaining whether the Soil, in which it is proposed to grow any particular crop, contains all that is necessary to produce a luxuriant vegetation; also to estimate the relative value and purity of Manures, and the comparative worth of Farm Produce in general. Gentlemen instructed in Agricultural Chemistry. The course will comprehend the Elements of Analysis.—No. 5 A, Hawley-road, Kentish Town.

LIQUID MANURE.

ENGLAND INDEPENDENT OF THE WORLD FOR CORN.

THE Attention of the Agricultural Interest, at this momentous crisis, is requested to the great importance of LIQUID MANURE, and the ease with which it may be appropriated, by the use of FOWLER'S PUMPS, made expressly for the purpose, either portable or fixed; Garden, Ship, and Barge Pumps; also those for Distillers, Brewers, Soap-boilers, and Tanners, for hot and cold liquor. Pumps kept for hire, for Excavations and Wells. Buildings heated by Hot Water, for Horticulture, and every variety of manufacturing purposes.

The Trade supplied on advantageous terms, by BENJAMIN FOWLER, Engineer, &c., 63, Dorset-street, Fleet-street, London.

CHEAP AND DURABLE ROOFING.

BY HER MAJESTY'S ROYAL LETTERS PATENT.

TO GARDENERS, NURSERYMEN, AND OTHERS.

F. M'NEILL & CO., of Lamb's Buildings, Bunhill-row, London, Manufacturers, and only Patentees of IMPROVED PATENT ASPHALTED FELT, for Roofing Houses, Sheds, Verandahs, &c., and for Protecting Plants, and Covering Garden Frames, beg to call the attention of Gardeners and others to their superior article, which has been exhibited at the Great Agricultural Shows of England, Scotland, and Ireland, and OBTAINED the PRIZE for being the best and cheapest article for roofing, &c. It has been tested in the gardens of several noblemen and gentlemen in the neighbourhood of London, and in different parts of the country, to many of whom reference can be made. The Felt is impervious to rain, snow, and frost, and a non-conductor of heat and sound. Its advantages are Lightness, Warmth, Durability, and Economy.—Price Only 2½d. per Patent 100 Square Foot. Samples, with directions for fixing, and testimonials as to its having kept free from leakage for a number of years.—Patent Felt Works, Lamb's Buildings, Bunhill-row, London.

AGRICULTURAL [illegible] the DERBY LEVEL.—The Proprietors of Lands desirous of draining their land [illegible] to this Level, are requested to [illegible] forthwith, addressed to the Clerk of the Commissioners, [illegible] Derby, stating the number of Acres they intend to be drained, and its price such Lands [illegible] within the Level, per Acre, at the end of the Maker; J. DAVIS, Engineer, Derby.

TANNER'S VITREOUS CLOTH, a SUBSTITUTE for GLASS for HORTICULTURAL PURPOSES.—The above recommends itself to the notice of Florists and Horticulturists, as producing effects superior to Glass, at a less expense. The support the Proprietor has received from very many highly respectable Florists encourages him to consider that his labours have not been misapplied in bringing before the public an article so generally required. Price of cloth, 9 yards of a yard wide, thin, 2s. 6d. per yard., stout, 3s. 1 yard wide, 3s. 6d. Price of Fluid (for renewing the cloth after lengthened service), 1s. 6d. and 2s. 6d. per bottle. Manufactured only by W. TANNER, Chemist, Exeter: and Sold by Messrs. Sutton and Mackley, Covent-garden, London; Mr. Cunningham, Paradise-street, Liverpool; Messrs. Lucombe and Pince, Exeter Nursery.

TO LANDOWNERS, AGRICULTURISTS, BUILDERS, &c.

MCKERROW'S PATENT ROOFING FELT is peculiarly applicable, as a substitute for Slate, Zinc, Tiles, and other preparations for Roofing, from its ECONOMY, LIGHTNESS, and DURABILITY.

The disadvantages attending other materials used in roofing, preventing, to a great extent, many useful houses and sheds being erected or rendered habitable, it is submitted that the improved Roofing Felt will in a great measure—and in some instances altogether—obviate them, and appears most serviceable from its lightness, durability, and impermeability to water and damp, in covering Houses, Cattle-sheds, Granaries, Ropewalks, &c., and for the slopes as well as roofs of glass structures for plants, being likewise a non-conductor of heat; besides its economy in repairs, the timber where it is used may be so light as to save its whole expense; it requires no other coping, and may be applied by any person of common ingenuity; being flexible and portable also, it is free from breakage, the expense of carriage is inconsiderable in comparison with slates, tiles, &c., and it is not liable to contraction like zinc.

Sold in sheets 32 inches by 20, at 5d. each (being less than 9d. per square of 100 feet), with printed directions for applying them, same as adopted at the Government Dock-yards and various other public buildings.

Orders will meet with prompt attention if addressed to H. C. BOWMAN, 16, East India Chambers, Leadenhall-street, London, or to the following Agents:—Liverpool, Messrs. Gruebar & Co., 11, Mapperly-lane; Plymouth, Thomas Stevens, Esq.; Birmingham, William R. Loyd, Esq.; Sunderland and Newcastle-on-Tyne, Messrs. John Rhson and Sons; Hull, William Ward, Esq.; Bristol, Messrs. Moor and Hewitt; Ramsgate and Deal, Messrs. Edward Hodges & Co.; Whitehaven, William Todd, Esq.; Glasgow, Malcolm Carmichael, Esq., St. Enoch-square; Cork, Messrs. Richard Wallis & Co.; Belfast, Messrs. Gruebar & Co., Donbar's Dock; who have also on sale McKERROW'S improved SHEATHING, BOILER, RAILWAY, and other FELT.

*** The "IMPROVED ROOFING FELT" will be found much more durable than the Common Felt made in lengths, and not subject, like it or continuous sheets of other material, to be stripped by storm; *it does not require to be either painted or coated*, can also be more easily repaired, and from the simple mode of application recommended, the wet cannot percolate through nail-holes, being only fastened down at the overlaps.

BURBIDGE AND HEALY'S COOKING APPARATUS, combining Sylvester's Patents.—This Cooking Apparatus is believed to possess greater general advantages than any yet submitted to the Public, both as regards strength of material and workmanship; in fact, the laws of heat are so applied as to produce the greatest effect with the least consumption of fuel, without destruction to the Apparatus; and B. & H. can safely recommend it, from experience, as unquestionably superior to anything of the kind hitherto made. A Prospectus can be forwarded, upon application, detailing particulars and prices, to 139, Fleet-street.

LEA AND PERRINS'S WORCESTERSHIRE SAUCE. Prepared from the Recipe of a Nobleman in the County.

"*Great Western Steam-ship, June 6, 1844.*—The cabin of the Great Western has been regularly supplied with LEA & PERRINS'S Worcestershire Sauce, which is adapted for every variety of dish, from turtle to beef, from salmon to steaks; to all of which it gives a famous relish. I have great pleasure in recommending this excellent Sauce to Captains and Passengers, for its capital flavour, and as the best accompaniment of its kind for a voyage. (Signed) JAMES HOSKEN."

"One of the most piquant inventions of this luxurious and epicurean age is Lea and Perrins's Worcestershire Sauce, adapted to fish, flesh, fowl, and soup; giving a zest far superior to the long-established favourites; more wholesome and of less cost —*Naval and Military Gazette*, April 8, 1843.

Sold Wholesale by the Proprietors, Messrs. LEA and PERRINS, Worcester; Messrs. BARCLAY and SON, Farringdon-street; and the principal Oil and Italian Warehousemen in London; and Retail by the usual venders of Sauces.

HEALTH, LONG LIFE, AND HAPPINESS.—EXTRAORDINARY CURE OF SCORBUTIC HUMOUR.

I, WILLIAM WOOD, of Rockwell Green, in the parish of Wellington, Somerset, hereby certify, that for about seven years I was afflicted with SCORBUTIC HUMOUR on my nose, with a continued discharge, rendering me almost unfit for society; I tried several medical men, and various medicines for curing the same, but all proved of no avail, producing no beneficial effect; at last I was persuaded to try PARR'S PILLS, and after taking two small boxes and part of a third, I was completely cured, and I now feel no pain or inconvenience as before. Many parties in the neighbourhood, and your Agent for Wellington, Mr. GREENWAY, can bear witness that my testimony is correct, and I wish it to be made known, that others similarly afflicted may be encouraged to try the same medicine, which under the blessing of God has proved so serviceable to me.

Witness my hand this 6th day of August, 1844. WM. WOOD.

In the presence of JOHN GREENWAY, Wellington.

From DR. C. STEARNS, 181, Fulton-street, sole agent for Brooklyn.—An instance of the singular efficacy of PARR'S LIFE PILLS, which merits particular notice, occurred in the person of a lady residing at Brooklyn, of consumptive make, who had been afflicted for upwards of six years with very great and general debility, headache, dizziness, faintings, and all the effects originating in an impaired constitution. Country air was tried, but to little advantage. She complained of weariness and pain on the least motion: her bowels were sometimes constipated, and at others lax, and never regular. At this period, she was recommended to try PARR'S LIFE PILLS, when no less astonishing than true, before she had finished two boxes, an entire and perfect cure was the result. To such nothing can equal this antidote, as it imparts tone and strength to the stomach, and operates so mildly, that the most delicate of either sex can take them with the greatest safety.

To T. Roberts and Co., April, 1844. Yours truly, C. STEARNS.

These, and hundreds of other cases of DECIDED CURES, attested on the highest authority, and already published, occupy upwards of 150 pages of letterpress. These Testimonials are published periodically, and may be had on application at any respectable medicine warehouse. The cures, in many instances, were effected after the most eminent had failed, and they thus establish the claims of PARR'S LIFE PILLS, in being considered the best medicine in the world.

CAUTION!! TO THE PUBLIC.—Beware of Spurious Imitations of the above medicine. None are genuine unless the words "PARR'S LIFE PILLS" are in WHITE Letters on a RED GROUND, engraved in the Government Stamp pasted round each box. Sold by all respectable Medicine Venders.

SUBSCRIPTIONS

NATIONAL TESTIMONIAL

TO MR. ROWLAND HILL,

UPWARDS OF FIVE THOUSAND PERSONS,

WILL CLOSE ON THE 15TH NOVEMBER NEXT.

On all the heritage of income stated in the recently published Quarterly Returns of the Public Revenue, some [illegible] a proportionate increase; the *Post Office*, on the contrary, the Revenue the Customs have increased 4½ per cent., the Excise 3½ per cent., the Property Tax 4 per cent., while the *Post Office* revenue, under its almost nominal rate of a penny, has increased eleven per cent., and the increase on the quarter has been even somewhat in excess of that.

These cheering results have been effected through the plan of *Penny Postage* in fact but *imperfectly tried*; the complete *celebration* of the Post Office Revenue to its amount before the Penny Postage was adopted is not an event, for distant, if it be fully and honestly carried out, and the *City of London Mercantile Committee on Postage* have it in their power to impress these satisfactory results most emphatically upon the Public, in announcing the approaching close of the National Testimonial to Mr. Rowland Hill. All parties, for unanimous upon this great commercial and economical triumph of the Post Office, the efficiency, as a *Financial* step, that even the most sanguine question have since acted, with the most decided success, to [illegible] it, or relinquish that the Old Postage Revenue had been absolutely stationary for twenty years,—retrogressive, in fact, if we consider the increase of population, education, and commerce during the period. The change which Penny Postage has effected, is to make the Post Office [illegible] the most frequent source of National income, bidding fair to become more profitable than it has ever been. The Committee, therefore, call upon the Public to respond, with [illegible] gratitude the Author of this great [illegible] benefit.

The Committee have no hesitation in announcing that the [illegible] Public, including the [illegible] political parties and of [illegible] [illegible] £10,000 [illegible] [illegible] every single [illegible] only a single [illegible] [illegible] [illegible]

KENNINGTON NURSERY
UNDER THE SPECIAL PATRONAGE OF HER MAJESTY THE QUEEN

RICHARD FORSTER AND Co., Successors to William Marsden, have much pleasure in offering the public an entire and correctly named Collection of FRUIT TREES of every desirable kind introduced to the country. These grounds, so highly favoured for the growth of every description of Nursery stock, and so long and so justly celebrated for its superiority, will well repay the visit of those who intend making a selection, for either autumn or spring planting, and their esteemed favours shall meet with prompt and correct attention.

GAINES'S SPLENDID FIRST-RATE SEEDLING PELARGONIUM, "Princess of Lapstone," was considered by all who saw it [illegible] one of the finest [illegible] which it obtained the Prize. Also the following Seedlings raised by Mr Gaines: "Alice Hawthorn" 1st, "Trafalgar" 1st, "Gaines's Alice Hawthorn" 1st, "Gaines's King of Bavaria" 1st, Gaines's Sir Wm. Manry Stanley" 1st; Gaines's "Marchioness of Lorne" 1st, Gaines's "King of the Frenchmen" 1st, with many first rate Seedlings raised by other cultivators. A good Collection of Pelargoniums, Pansies, Calceolarias, Camellias, Cinerarias, Fuchsias, Verbenas, Chrysanthemums, Carnation Picotees, Auriculas, &c., may be obtained of Mr Gaines, Surrey Lane, Battersea.

P S The collection of Seedling Cotees raised by Mr Milner are now in blossom, and may be seen at the above Nursery

LYNE'S NEW GERANIUMS.

WILLIAM L. RENDLE can execute a few more orders for the following

Lyne's Prince of Alice	each	21s
" Redworth		21s
" White Perfection		21s
" Confidence		21s
" Imogene		21s

Plants will be delivered after 15th November "Jaffino" cannot be sent out this season; no more orders can be received for "King of Saxony"

LYNE'S "PRINCES" 10s 6d each.

*** The stock of the above is limited to about 2 plants of each; early orders are therefore necessary to insure a supply.

Union road Nursery, Plymouth, Nov 2 1843

TULIPS, HYACINTHS, RANUNCULUSES, ANEMONES, RANUNCULUS, AURICULAS, CARNATIONS, and LILIUM LANCIFOLIUM.

HENRY CROOM, Clapham Rise, near London (removed from Walworth), by Appointment Florist to Her Majesty, begs to recommend to the attention of the Nobility, Gentry, and Public his extensive assortment of the above flowers which, from the exceeding skill he has in their cultivation he can offer at very moderate prices. He particularly wishes to call attention to the highly-flattering remarks on his Exhibition of Tulips and Lilium lancifolium in the various papers. He is also desirous of reminding the Nobility, Gentry, and Amateurs, who may wish to add to their collections or ornament their parterres with these beautiful flowers, that this is the best season to make a selection. The varieties of the splendid Lilium lancifolium are particularly adapted for pots, as, besides being quite hardy, they flower at a time when the Nobility and Gentry are at their country seats, and which flowers are so much wanted. They only require to be known to be universally cultivated. Catalogues may be forwarded by post on application. Foreign orders executed.

DOUBLE ROMAN and PAPER-WHITE NARCISSUS, 4d. per dozen. The above Bulbs, the flowers of which is so justly esteemed for its early blooming and delightful fragrance, and the latter for its purity and elegance, have just received at A. Constable's, late Mr. Barnard's, Old Foreign Warehouse, 18, Pall Mall. Also Dutch Hyacinths, Crocuses, Tulips, Anemones, &c. &c.; Prize Catalogues which may be had per Post.

GREAT YARMOUTH NURSERY NORFOLK, 1844

UNDER THE ESPECIAL PATRONAGE OF HER MOST GRACIOUS MAJESTY THE QUEEN DOWAGER, H.R.H. THE DUCHESS OF KENT, THE RIGHT HON. LORD COLTENHAM, THE EARL OF ORFORD, THE EARL OF RADNOR, AND THE HORTICULTURAL SOCIETY OF LONDON, &c. &c.

A Letter, of which the following is a copy, has been received from the Hon. Wm. Ashley, Treasurer, to the Queen.

SIR, PAVILION, February 22, 1837

I am commanded by the Queen to acknowledge the receipt of a basket of Tobolsk Rhubarb sent by you for Her Majesty's acceptance, and to say that its excellent qualities fully justify the high character you had previously given it.

I remain, Sir, your obedient humble servant,

To Mr WILLIAM YOUELL (Signed) WILLIAM ASHLEY

Horticultural Establishment, Yarmouth

YOUELL'S TOBOLSK RHUBARB.—This highly-esteemed variety will be found to be the earliest of all early sorts as well as the most hardy. As a proof of its extraordinary precocity it has been ready for tarts as far the 20th of February on the open garden in a very exposed situation, and continued to produce its fine large stalks till September.

How could we be useless to eulogise its merits further than the great demand for it, together with the many high testimonials of approbation received, claim for it a decided superiority.

The TOBOLSK RHUBARB may be grown in boxes or pots in any common garden mould or even exposed in damp Moss and placed in a cool dark cellar, the back fire recommended, where early in October, under the same treatment as Sea Kale and will be ready, when it will produce its tasks of a beautiful transparent delicate pink containing a rich vinous juicy pulp entirely free from the disagreeable acid flavour objectionable in all cases with and when cooked retains its beautiful colour, which renders it an elegant addition as well as delicious dish to the table of a season when vegetables are unattainable. It splendid for the early part of the month will read for cutting in January. A few boxes will be sufficient for every three weeks will afford a regular supply and the plants, when done with, may be planted out in the garden in the summer, and replaced in the cellar, as in Sea Kale.

It will be observed that the prominent features in this variety is the tender manner in which it may be cultivated with certainty from seed by the aid of a hot-bed, a little attention to the early stage of its growth, and will be a desideratum to the cultivator of the kitchen garden.

Also, Myatt's Queen Victoria Rhubarb 12s per dozen

Youell & Co., Great Yarmouth Nursery, October 31st

THE NEW SUPERB SEEDLING PICOTEE "DURROUGHES'S DUKE OF NEWCASTLE"

WOUELL & CO. have much pleasure in announcing that they will send out for the present season this splendid light edged purple Picotee raised by the Rev. Burrough Durrough and named in honour of the Duke of Newcastle. With just claims to surpassing Purple Picotee that has yet been raised. Without comment we further upon its superiority, but beg to refer to a report in a late No. of the *Gardeners' Chronicle* as follows —

"The *Duke of Newcastle* is a flower of first rate properties; the bright edged purple the petals are large, and of good form and substance, even on the edge the colour running the whole round will be a desideratum to the exhibitor." It gained the first prize as the best seedling at the Norfolk and Norwich Horticultural Exhibition. Price 21s per pair. The stock being limited to prevent disappointment early orders are respectfully requested. Y and Co are also enabled to supply the following superb Picotees, raised by the same gentleman all of which are first rate properties and have been exhibited and obtained first class prizes at several of the metropolitan exhibitions this present year. The names will

Duke of Wellington		5s 0d
" Lady Alice Peel		5 0
" Miss Revell		5 0
" Mrs Revell		5 0
" Lucy		2 6

CARNATIONS AND PICOTEES

Youell & Co's collection of these beautiful flowers is known to be one of the finest extant containing every known variety of merit. The plants are remarkable strong, and healthy, and will be found to answer to the title Bizarres, Flakes, Rectes, &c. &c. as described in their Catalogue, which will be sent on application.

The selection being left to Youell & Co

Great Yarmouth Nursery, Oct. 31

SPERLING begs to refer the Readers of the *Gardeners' Chronicle* to his Advertisement of PETUNIAS, DOUBLE VERBENAS DAHLIAS, &c., of the 14th October Dancroft Nursery, Stowmarket, Suffolk.

CARNATIONS AND PICOTEES.

JOHN DICKSON, Acre-lane, Brixton, Surrey, has prepared for the flowers of these splendid flowers a Catalogue, enabling them to judge of their qualities, with the prices annexed, which they may be had as the Nursery, and on and after Wednesday next, October 4, [illegible]

J. DOIG begs respectfully to inform the Nobility, Ladies, and Gentlemen that his CATALOGUE of Hardy Herbaceous Plants, Alpines, Trees, Shrubs, Greenhouse Plants, &c. is now ready for delivery, and will be forwarded Gratis on application. [illegible] Catalogues when they are thus applied for.

Langley Nursery, Nottingham, Oct. 26, 1843.

TO THE LOVERS OF ROSES.

WOODLANDS NURSERY, WORTHING, UCKFIELD, SUSSEX, AND AT PARIS.

WILLIAM WOOD and SON have the honour of submitting to the notice of their Nobility and Amateurs, the undermentioned truly magnificent Collection; it has flowered here this season in great perfection, and Plants were forwarded to Dr LINDLEY, whose opinion appeared in the *Gardeners' Chronicle* page 684:

MARGARET MARY (Wood's).—"Your seedling, Gillian, is a handsome variety, fine in form, being compact and well double, outside petals finely cupped; in colour it is of a purple rose, of a peculiar and beautiful tinge; it is fragrant, and it its best when fully expanded."

Plants of the above are now ready for immediate delivery at Standard and Dwarf at 5s each. The usual discount to the trade when not less than six plants are ordered at once.

W. W. and Son further beg leave to state that they have on hand a very extensive stock of Roses at the following prices, when the selection is entirely to them —

	Per doz	Per 100
Superior selected Standard Roses	18s	£ 5 0
Superb do do	9 or 12	10 0
Select Dwarf budded do	12	15 0
Superb do do	18	5 0
Superior dwarf Roses (on own roots)	9	7 10
Superb do do fine show varieties	12	2 15
Fine Climbing do	9 and 12	2 10

Catalogues of Roses and Nursery Stock will be sent gratis on application.

A List of this will be presented GRATIS, in order to compensate the expense of carriage. A remittance, or reference will be required from unknown correspondents.

TO THE PLANTERS OF ENGLAND—TRUE HIGHLAND PINE.

JAMES GRIGOR, NURSERYMAN, Norwich, begs to remind such of the Planters of England and Scotland as wish to enhance the beauty and value of their estates, that he is now sending out plants of this recently introduced and very valuable timber tree at the undermentioned prices —

Single plants, strong and well rooted	6d. each.
8 strong plants, 10 inches high	2s per doz.
Do 12 do do	3s. per doz.
Smaller sized plants	from 10s. to 20s. per 1000.

For introducing this tree Messrs Grigor, of Moray and Forres, were awarded several premiums by the Highland and Agricultural Society of Scotland, where it is rapidly superseding the Scotch Pine. In its old age it assumes in a great measure the appearance and grandeur of the Cedar of Lebanon, and therefore is valuable for planting in masses throughout the Park or pleasure ground, or for distant landscapes. The young trees might be confounded at a little distance with the Silver Fir, but it is at once distinguished from it by the leaves growing in pairs, instead of singly as in the Silver Fir. It is also distinguished from the Scotch Pine by the leaves growing in pairs, instead of three together as in the Scotch Pine.

TO PEAR GROWERS

RENÉ LANGLIER, NURSERYMAN and FLORIST, CLARENDON NURSERY, ST HELIER, JERSEY, begs leave to draw the attention of Pear growers to his new PEAR named LANGLIER'S HEURIEL, of first rate merit, perfectly melting ripe in January; shape of Napoleon, but larger in size; standard tree very vigorous; one of the best flavoured Pears known, otherwise it would not be recommended by R. L., as he gives for advertising is not for the sake of publishing, but for the good of the public in general, to whom he is happy to have the opportunity of rendering himself useful; of which, "A Man I am in Glass," will be a sufficient guarantee, having proved itself as it was represented, and given universal satisfaction. The stock of this superb New Pear is small and limited in number, and the price will be 21s; if 6 trees are ordered, 7 will be sent; no discount will be allowed to the trade. As the trade only will 6 plants be sent for 10, the number is very limited. R. L. also takes this opportunity to state that to those numbers of "A Man I am in Glass" remain unpaid for on account of some will be sent to unknown correspondents, except for ready cash, or post office [illegible]

As this is unexpected for plants, R. L. wishes to draw the attention of the public to his well-selected and unrivalled Collection of which a list may be had by pre-paid letter, and begs to state, that nothing is sent from his Establishment except proved fruit and [illegible] R. L. also wishes to obtain a few thousands of small plants of EVERGREEN OAKS, among which will be [illegible] rear varieties, they are fine and healthy, 2 years old and [illegible] inches to 24 feet high, fit for planting or potting, price 2 per 100. Also the KIDNEY POTATOES, superior in [illegible] equal to the Ash leaf, the sample, extra fine, as [illegible] sold weight, as not [illegible] that quantity will be sent.

HARDY SHRUBS AND HERBACEOUS PLANTS, &c.

WILLIAM MAY, Hall, cultivating the above in large quantities is enabled to offer them on the very most reasonable terms, a few of which are respectfully begs to call the attention of [illegible] about to make new or add to old plantations. He can recommend them as being all very fine varieties, well adapted for display, and not for mere botanical curiosity. The plants are strong and healthy and will be correctly named. Hardy Shrubs, two each, 4s per 100, if 100 taken at once; 100 or more sorts will be sent, the 500 for 10l. Hardy Herbaceous Plants, 100 sorts for 4s or 200 sorts for 8s; the selection left to W. M. Victoria late Red Currant, 10s. a dozen; Hollyhocks, fine double sorts at 4s per 100. (See Advertisement, *Gardeners' Chronicle* Oct 5.) Remittance or reference from unknown correspondents.

Hope Nursery, Thorne, Yorkshire, Nov 1

The above superlative bulbs may be depended on as of first-rate quality, and may be had at the low prices annexed, delivered free in London from Messrs. SUTTON and SONS, Reading Nursery, Reading, Berks.

A SPLENDID NEW LATE PEACH.

MORTON'S "WALBERTON ADMIRABLE."—This splendid variety was raised at Walberton House, in Sussex, the seat of R. Prime, Esq. It is a Seedling from the Noblesse, which it much resembles, both in size and flavour. It possesses all the fine qualities of its parent, but its great merit arises from its ripening full five weeks later. A specimen of the fruit was sent to Dr. LINDLEY, in 1841, from whom were received the highest testimonials of approbation. The tree is a fine, free, and hardy grower; the fruit is full-sized, melting, and excellent-flavoured, rendering it a truly desirable variety, and one which no good garden ought to be without.

Good one year's trained plants can be obtained of ALEXANDER WEBB, Nurseryman, Westergate, near Arundel, Sussex; at Messrs. HAY, ANDERSON, and SANGSTER'S, Newington Butts; and also at Messrs. HURST and M'MULLEN'S, 6, Leadenhall-street, London, at 18s. 6d. each; a few strong plants at 21s. each. The usual allowance to the Trade when three or more are taken, and carriage paid to London. Remittance from unknown correspondents is required.

WOODLANDS NURSERY, MARESFIELD, NEAR UCKFIELD, SUSSEX; and at PARIS.

WILLIAM WOOD AND SON beg leave to offer their extensive Stock of CAMELLIAS, fine Stocky Plants, well furnished with Flower-buds, at the following prices, the selection of sorts being left to themselves.

F. likewise begs to inform his friends that his extensive collection of PANSIES are at this time particularly fine and healthy. Catalogues of which, including Florists' Flowers, Greenhouse and Herbaceous Plants, &c, &c., are now ready, and will be forwarded on application.—Clarendon Nursery, Camberwell, Nov. 1.

"GENERAL TOM THUMB" SCARLET PELARGONIUM.

PHILIP CONWAY, NURSERYMAN & FLORIST, &c., Old Brompton, through the kindness of Mr. Ayres, is enabled to let out a few plants of the above, which is thus described in the *Gardeners' Chronicle*, page 580:—

"Unquestionably the finest Dwarf Pelargonium out is that which has this season been exhibited under the name of 'General Tom Thumb.' It grows almost prostrate, is exceedingly rich and dense in foliage, and produces with the greatest profusion large trusses of the most dazzling scarlet flowers imaginable. I have a plant at this moment nine inches high and six feet in circumference, studded with 27 trusses of expanded bloom, and some of the trusses six inches in diameter; and on five plants there are upwards of 120 trusses of flowers."

For both pot cultivation and bedding out this plant is unequalled. Plants 3s. 6d. each, or 36s. per dozen, with the usual discount to the trade if six are taken at one time. N.B.—At the June Exhibition of the Regent's-park Society a prize was awarded to the above; also to the following desirable variety of scarlets, viz.:—

Frost's Superb, a splendid pot plant	2s. 6d.
Mrs. Mayler, a very superior variety	2 6
Cooperii dwarf, for bedding	1 6

JOHN CARTER, Seedsman and Florist, 23B, High Holborn, London.

CHAPMAN'S KIDNEY POTATO.—Messrs. C. and T. CHAPMAN, of Brentford End, are desirous to supply others with their POTATO at 12s. per bushel; any parcels desirous of seeing the quality and the yield can do so by applying to Mr. T. CHAPMAN, Sion Hill, Brentford End, when instructions for their preservation and culture will be given.—Nov. 2,

ELIGIBLE ESTABLISHMENT IN BUSINESS, IN KELSO, ROXBURGHSHIRE.

MR. LOCKIE, SEEDSMAN, finding it expedient, from his other occupations, to relinquish the Wholesale and Retail Seed Trade, &c., conducted by his late father and himself for upwards of 57 years, is ready to dispose of the BUSINESS and STOCK in TRADE; as also to let the Shop and House in the Market-place, and Granary in the Horse Market, to any party wishing to obtain so eligible an opening.

Mr. Lockie will continue the business as usual until an arrangement is made; but the party intending to succeed to it may have immediate entry to the whole premises.—Apply to Mr. GEORGE MAIN, Writer, Kelso.—Oct. 26.

EDWARD BECK informs the Public that in consequence of the greatly increased demand for his SLATE TUBS, he is enabled to reduce the price of the following sizes about 10 per cent. He regrets the too frequent delay which has occurred in the execution of orders. This he hopes to avoid in future by keeping a supply on hand. Their suitability to the growth of every description of plant is fully established, and their imperishability and consequent economy is beyond dispute.

The following plants have been exhibited by E. Beck in slate:—Orchideæ, Heaths, Pelargoniums, Calceolarias, Stove-plants, Specie, Fuchsias, and Roses. The prices obtained by him last season at the Horticultural and Botanical Society's Exhibitions, were, 7 Gold medals; 3 Silver-gilt; 9 Silver; 4 Certificates of Merit. Prices for Cash or Post-office order:—14 in., 11s. each; 18 in., 12s. 6d.; 18 in., 15s.; 18 in., 19s.; 20 in., 22s. 6d.; 22 in., 25s.; 24 in., 35s.—Slate Works, Isleworth; Middlesex.

WHITNEY'S PATENT CLOTH for COVERING GREEN-HOUSES, CUCUMBER or MELON PITS, &c. This Cloth is made expressly for the purpose of applying Whitney's Composition upon, and is much more durable than any other material; when coated it is beautifully white and transparent. The perfect success of Whitney's Composition for all Horticultural purposes cannot be more fully established than by stating, that, on the 1st of April last, a Black Hamburgh Vine was set in a border, the stem introduced into a house covered with Calico, and coated with Composition. On the 1st of Sept. a bunch of Grapes was cut weighing 16½ ounces, the fruit was finely coloured, and the flavour pronounced to be excellent. A sample was sent up to the Editor of the *Gardeners' Chronicle* for his inspection. The tree grew very luxuriantly, the foliage very fine, and the wood ripened exceedingly well. As a winter protection it is infinitely warmer than glass.

The PATENT CLOTH and COMPOSITION can be obtained of Messrs. Bother & Muckley, Covent Garden Market; Hurst & M'Mullen, Leadenhall Street; Warner & Warner, Cornhill; Barclay & Sons, Farringdon Street; and Hannay & Co., Oxford Street.—Wholesale and Shipping Agent, Mr. Bailey, Wolverhampton.

ST. ALBAN'S, HERTS.

UNRESERVED SALE OF NURSERY STOCK.

MESSRS. PROTHEROE AND MORRIS are instructed by the Executors of the Mortgagee (in consequence of the Estate having been disposed of), to submit to public competition, on the premises, the Key Field Nursery, St. Alban's, on Monday, Nov. 18th, 1844, and following days, at 11 o'clock, the whole of the valued NURSERY STOCK, comprising Fruit and Forest-trees, Evergreens, Ornamental, Deciduous, and American Plants of every variety, and about 3000 Standard and Dwarf Roses, consisting of the choicest varieties; 1,000,000 Quick and Oaks, of different ages; Seedling Beech, Ash, &c., 8cb Kale, Asparagus, and Rhubarb, Dahlias, and Herbaceous Plants. The lots will be arranged to suit large and small purchasers. May be viewed one week prior to the Sale. Catalogues 6d. each, returnable to purchasers, may be had on the premises, of A. A. DOSSETT, Auctioneer and Land Surveyor, St. Alban's; of the principal Seedsmen in London, and of the Auctioneers, Leytonstone, Essex.

BROMPTON-PARK NURSERY AND SEED ESTABLISHMENT.—ESTABLISHED 1681.

MESSRS. GRAY, ADAMS, AND HOGG have much pleasure in directing the attention of their numerous customers to their extensive NURSERY STOCK, consisting of Dwarf and Standard Maidan and Trained Fruit-trees, Figs, Vines, &c. &c., all of which are this season of a very superior description, and will fully maintain the reputation this establishment has for such a long period of years enjoyed for producing these articles. The peculiar nature of the soil renders the removal of all ornamental trees and shrubs almost certain, of which there is a select and extensive collection; together with everything that is desirable in the class of Greenhouse and Herbaceous Plants.

MARKET GARDENERS are invited to inspect a fine stock of Half Standard Apples, Pears, and Plums, which they will find well worthy their attention.

The SEEDS of this season that have come to hand are generally of a very fine quality, and of which Catalogues will be issued in due course.—Kensington-road, Nov., 1844.

TO GENTLEMEN, NURSERYMEN, AND OTHERS.

LAVENDER-HILL NURSERY, WANDSWORTH-ROAD, NEAR LONDON.

During the present month, will be sold, by Auction, unless previously disposed of by private contract, the valuable and healthy NURSERY STOCK of the late Mr. W. PAMPLIN, by order of the Executors, consisting of about Nine Acres of general NURSERY STOCK, particularly abounding in the Finest HARDY EVERGREENS, of all sizes; FRUIT-TREES, SHRUBS, and PLANTS; Large and Small CAMELLIAS, an extensive Collection of FERNS (some of extreme rarity); Erection of Greenhouse, Garden Frames, and Lights; Garden Implements, Shop Fixtures, quantity of Vegetable and Flower Seeds of the present Harvest, including a half-cwt. of best White Spanish Onion, Early Cauliflower, &c. &c.

Due notice of particulars will be given in a future advertisement. Meanwhile, parties contemplating purchasing the Leases of the Premises will be treated with at once, and may learn full particulars, and may inspect the Leases, on applying to Mr. W. J. LOAT, Clapham Common; or to Mr. W. PAMPLIN, Bookseller, 45, Frith-street, Soho.

LAVENDER-HILL NURSERY, WANDSWORTH-ROAD.—IMPORTANT LEASEHOLD PROPERTY to be Disposed of, by order of the Executors of the late Mr. W. PAMPLIN, Nurseryman. These valuable Premises with extensive frontage, most beautifully and eligibly situated, and capable of much improvement, consist of the substantial DWELLING-HOUSE, in capital repair,—dining, drawing, and large sitting-rooms, five good bed-rooms, and large underground and other domestic offices; Stable, Lofts, Sheds, and other Buildings; about NINE ACRES of LAND, occupied as Nursery Ground. The whole (well adapted for a moderate family, or a Nursery and Seedsman, or for scientific and experimental Agricultural purposes) will be sold by public Auction during the present month, unless previously disposed of by private Contract.

For particulars apply to Mr. W. J. LOAT, Clapham Common, or to Mr. W. PAMPLIN, Bookseller, 45, Frith-street, Soho.

HANTS.

TO BE LET, with immediate possession, a most desirable TENEMENT FARM, containing about Six Hundred statute Acres of Arable and Pasture Land, surrounded with good Markets. Also, a good WATER CORN MILL, adjoining the above Farm.

For particulars apply to WILLIAM PADWICK, Esq., Manor House, Hayling, Havant, Hants.

CATALOGUE of ROSES, FRUITS, TREES and SHRUBS.

T. RIVERS, of the Nurseries, Sawbridgeworth, Herts, has the following Catalogues now ready for delivery on receipt of postage stamps as follows:—

Catalogue of Roses, No. 1, Edition for 1844	2d.
Supplement to ditto, containing the new varieties of Roses, with lists of Roses in extra-sized pots, for Exhibition, Forcing, and Greenhouse Culture	2d.
Catalogue of Roses, No. 2, containing the old and esteemed varieties, and Climbing Roses	2d.
Descriptive Catalogue of Fruits	2d.
Descriptive Catalogue of Trees and Shrubs	2d.
Descriptive Catalogue of Pears, with directions for root pruning, three engravings of Pear-trees, trained conically and en quenouille; with supplement to Catalogue of Fruits	1s.

The latter is sold also by Messrs. LONGMAN and Co., and Mr. KERNAN, 4, Great Russell-street, Covent-garden.

The Gardeners' Chronicle.

SATURDAY, NOVEMBER 2, 1844.

MEETINGS FOR THE TWO FOLLOWING WEEKS.

TUESDAY,	Nov. 5	Horticultural	2 P.M.
		Linnean	8 P.M.
SATURDAY,	Nov. 9	Royal Botanic	4 P.M.
WEDNESDAY,	Nov. 13	Microscopical	8 P.M.

Now that the POTATO-CROP is gathered in, and the result known of any experiments that have been made upon its growth, we shall be obliged to our friends for such data upon the subject as their experience may furnish. The subject is too important to be consigned silently to the ordinary columns of correspondence, and we are anxious to have the opportunity of making some editorial observations introductory to the experiments. As soon as time has been given for the communication of the returns we solicit, the matter shall be taken up and disposed of.

A FORTNIGHT since we described the French method of forming TULIP-BEDS: we now continue the translation by giving their system of planting them, their diseases, &c.

"From the 10th to the 25th of November, (supposing the beds to be properly prepared,) is the best time to put the bulbs in the earth. This is accomplished by stretching strings from one end of the bed to the other, causing them to make slight depressions, thus forming five longitudinal lines at equal distances on the surface. The most expeditious way of crossing these with transverse lines is to take a piece of wood, the exact width of the bed, pressing it down lightly on the soil as often as required at the distance of 6 inches apart.

"The section of these lines indicates the exact point where the bulb ought to be planted. At each of these points a hole is made with a trowel, about an inch and a half in depth, into which is poured about a wine-glassful of very fine sand, on which the bulb is placed. It is then covered with a similar quantity; this permits the wet to filter through it, and is a preventive against too much moisture. Each bulb is then gently pressed down, and covered with a little hillock of earth. It has been clearly demonstrated by various experiments, that the plan of many people, who make the holes for the bulbs with their fingers or with a planting-stick, is altogether preposterous and absurd: by the pressure, the soil is rendered much more compact, and less suitable for the proper development of fibres, as well as preventing a proper drainage."

The above coincides very much with our own practice; and to the latter assertion of the impropriety as well as impolicy of using a blunt setting-stick, we can, from experience, add our own testimony, as we well recollect a bed of Tulips being nearly ruined by planting the roots in stiff loam when rather wet; the holes were made with a blunt dibber, and the bulbs placed carelessly in them. We saw the bulbs removed, and discovered that the bottom of the holes, as well as the sides, had been so compressed, that they actually retained the rain-water which fell on the bed, and in most instances, the roots, unable to penetrate, had turned upward by the side of the bulb in search of nutriment.

Our Author then proceeds with the necessary directions for covering the bulbs, "which ought to be with fine loam, of an equal thickness, of about four inches; the earth round the bed is then gently sloped off, and beaten hard, so as to render it as solid as possible, and afterwards covered with a thin layer of a sort of mortar made of peat-soil, Grass seeds, and water, well beat up together. Peat-earth is preferable for this purpose, as it is not so liable to crack as loamy soil in drying, and the Grass seeds are enabled to vegetate more quickly in it, giving consistency to the edges of the bed, speedily forming a beautiful turf, and contributing to the beauty of the whole. A stone curb or border has certainly many advantages, affording no protection to snails or noxious insects, as well as economising time in the formation of the beds, but the cost is great."

We agree with the writer that the first outlay is considerable in having beds edged with stone or with slate, which latter description of curbing we should prefer; still we think the expense would soon be saved in the labour, &c., which Grass borders must necessarily require to keep them neat and trim, independently of the cleanliness and durability of slate, &c. We find, however, that the system adopted by the most extensive Tulip-growers, of surrounding the bed with Oak or red deal planks, about 12 inches in depth, appears to give satisfaction; and when these are surmounted with a slight rail about 18 inches high, and the whole painted white (contrasting with the foliage, &c.), it has a very good effect. And as a preservative, and at the same time contributing to the *finish* of the Tulip bed, we would always recommend a neat lattice-work, about 4 feet high, fastened to the upright pillars of the shed, and completely surrounding it. The protection afforded by it is invaluable at that trying of all seasons, March, in breaking those fearful blasts which sweep over undefended beds with untiring energy, and often with serious consequences to the ensuing bloom.

"Exposed to sudden changes of weather, Tulips are liable to injuries which it is necessary to prevent. From the 15th of February to the 15th of April they are generally exposed to snow, frost, and heavy rain, at which time the leaves, just rising from the ground, form a kind of funnel, at the bottom of which is the flower-bud; these retain the water, which filters down, either destroying the root, or so far affecting it as to seriously injure the advancing bloom; the extent of the injury depending on the time more or less that the bud has been enveloped in water. Hailstones often cause great damage, wounding the petals, and defacing their beauty. Many other accidents to which Tulips are exposed might be enumerated, but the limits of this article would be too far extended, were I to enter into further details in this respect."

We are sorry that our Author does not enter more largely into the diseases, &c., with the precautions necessary to be observed, as great attention ought to be directed towards the Tulip. As soon as it makes its appearance above ground; those who would successfully exhibit will hoop their beds, and defend them from frost with mats; but a most excellent precaution, and one which we would strongly recommend, is to put fine sand on them, as soon as the plants appear above ground, and before the leaves have advanced so far as to separate, enveloping the rising plant in a complete cone; this is preferable to covering with soil, as it excludes frost better, does not retain wet so long, and is a preventive against canker.

Should the latter disease, however, attack the foliage, we immediately remove the soil below the affected part, and with a sharp knife cut it away altogether. Exposure to the air soon heals the wound, and the bulb is saved. We imagine that the most serious injury which the bloom sustains is when the hollow formed by the rising leaves gets filled with water (as noticed above), which, when it becomes frozen, imbeds the bud in a solid mass of ice, proving highly detrimental. To prevent this, the water must be removed, either by blowing it out, or drawing it up with a syringe. Should the buds escape injury in this manner, they must be carefully defended from hailstorms, which come on so suddenly as sometimes to preclude the chance of protecting them; small-meshed net, or damaged lace, spread over the hoops, will prove an efficient preventive.—*W.*

WE doubt not that a LETTER, in another column, from NEW ZEALAND, written by a gardener there to the late Mr. LOUDON, and received since that gentleman's death, will prove highly interesting to our readers, who have to thank Mrs. LOUDON for the kindness she has shown in allowing it to be made public. It is so difficult to judge correctly of the condition of a distant colony from the representations made by interested parties, that documents of this sort are invaluable. To us, the letter in question is the more acceptable, because it completely confirms all that we have constantly asserted regarding the climate and capabilities of that colony, which has nothing to dread except the mismanagement of the British Government.

ENTOMOLOGY.

AMMOPHILA SABULOSA (*the Grave-digging Sand-wasp*).—The economy of insects is so marvellous and interesting, that the introduction of the histories of those which may not be directly concerned in the destruction of our crops, needs, we hope, no apology; and as it is absolutely necessary that the gardener and farmer should be as well acquainted with their friends as with their enemies, we shall from time to time treat of the parasitic insects—most extraordinary agents which are employed by the Ruler of the Universe to subdue those plagues which without His interposition would despoil this fair earth of its beautiful vegetation, in spite of the best efforts of man.

I have therefore much pleasure in recording the history of a Sand-wasp, which labours incessantly and with incredible perseverance in the destruction of caterpillars and spiders, which it buries underground to support its offspring; and as one egg only is laid in each victim, and the Sand-wasps are very numerous, the amount destroyed by them must be very great.* About the 10th of June my friend Dr. Macleun pointed out to me a female Ammophila busily engaged in removing the earth from a hole in a south border, in order to bury a caterpillar, previous to laying an egg upon it. She kept entering the hole, vibrating her wings with apparent delight, which caused a distinct buzzing, like a large blue-bottle fly in a spider's web; every second she brought out a morsel of earth or a little pebble, which she threw down several inches from the hole, whilst on the wing; having at last excavated so far that we lost sight of her, we left the place, and found it so admirably closed the following day, that it would have been utterly impossible to discover the spot, if previous observations had not been made; two or three pebbles had been laid near the aperture, one of which, being flat and white, my friend very happily designated the gravestone, for upon digging we found a cell about two inches from the entrance, where a fat green larva, probably of some Noctua, was entombed; and on one side, close to a spiracle, upon the segment preceding the first pair of abdominal legs, was attached by one end a long elliptical egg, looking like a little fish's bladder, without any appearance of segments. In all probability it is not long before the trophi are developed, and the larva perforating the blackened end of the egg, the organs of manducation are inserted, like the seta of Scolia flavifrons, into the caterpillar, after which it rapidly increases in size, the extremity first dilating, the segments becoming visible in a few days, and in a week the spiracles, at which period it was about ¾ of an inch long, cylindrical, shining, and of a whitish colour (fig. 2); the viscera were constantly in motion, undulating like yellow waves; the head was small, round, and armed with jaws and minute palpi; at this time scarcely anything but the skin of the caterpillar was left, with the exception of the anal legs, which remained of a green tint; but the animal was alive a few days before, and evacuated several pellets of dung after it was buried. The extremity of the maggot is conical, and I could not detect the slightest deposit from it. On the 19th every vestige of the caterpillar, not excepting the horny head, had disappeared; the head and thoracic segments of the maggot became attenuated, the sides exhibited a thickened margin, and a limpid drop exuded from the tail; it now began to spin an oval cocoon of the finest texture, shining, and resembling oil-case or gold-beater's skin, of an ochreous colour, and having a few loose woolly hairs on the outside, adhering to the surrounding particles of earth; within this was a narrower detached case forming the pupa, of a substance resembling the inner bark of a fir-tree, and not unlike it in colour; it was wrinkled longitudinally, but very smooth inside, appearing varnished, and of a rust colour, the exuvia lying at the lower extremity, which was pitchy externally.

On the 30th of July, a *female* Sand-wasp issued from the case, and it proved to be the Ammophila sabulosa of Linnæus (fig. 1). It is dull black, clothed with soft brownish hairs; head and thorax covered with shallow punctures; the former is large and furnished with long, powerful jaws, the maxillæ and labium forming a beak, with four slender palpi;† the eyes are large and lateral, the ocelli placed in triangle on the crown; the antennæ are rather short, curved at the apex, and 12-jointed; the trunk is oval; the scutel and metathorax are finely striated; the extremity of the latter and a spot on each side of the medipectus are of a yellowish satiny hue; abdomen long and clavate, forming a very long, slender pedicel at the base, and a stout oval mass at the extremity; the second joint of the petiole is red, except at the base; the following segment and the basal margin of the fourth are of the same colour; the four wings have a smoky tinge, forming a border at their extremities, and the third submarginal cell is not pedunculed; the legs are powerful, the four hinder elongated; the tarsi are spiny, especially the anterior. It is 10 lines long and 12 in expanse. The *male* is much smaller, has 13-jointed antennæ; the face is silvery; the third abdominal segment has an elongated black spot on the disc, and the tarsi are much less spiny than in the female.

I wished to have entered upon a comparison of our larva with that of Scolia flavifrons, of similar habits, and so ably illustrated by Professor Passerini; but I can only observe that the Scolia egg is laid upon the larva of Oryctes nasicornis, and that the head of the maggot is furnished with a long seta. The curiosity of the reader may be gratified by a reference to the two Memoirs lately published at Florence.—*Ruricola.*

† Vide Curtis's Brit. Ent., pl. 604.

THE ROSE-GARDEN.—No. XX.

(Continued from p. 684.)

The choice of scions is regulated by the same rules as the choice of buds, only that in choosing scions some reference must also be had to the size of the wood, which should have a sufficient thickness to keep it from getting dry easily, and to facilitate the operation of cleaving the stock. The best buds are generally near the base of the shoot than the summit, but two or three scions may sometimes be obtained from a single shoot. No scion should be used when the buds upon it appear to have shrunk and lost their fullness from having been laid by, although care should be taken, on making their selection, that the wood of the stock for the scion bears a sound bud. The chief purpose of using the scions, that a piece of the bark be brought between them and the stock in such a manner as serves to protect the cleft in the centre of the scion from the air, and to leave the vacuum to be filled up with cells of living [illegible] stock from the [illegible] and to leave the [illegible] vacuum to be filled up with cells of living [illegible] stock.

Should any grafts fail, which will be seen in a longer or shorter space of time according to the weather, in moist, dull, growing weather it will soon show, as that which is dry, wind, or heat during will be dried, the resource is still left of looking for the buds and observing for any the fresh buds which may spring from the stock in which case the stock should be cut immediately above them, and budded in the following month as usual. Grafting the stock, however, is never to be used to heal over the wounds, in which the scion should be nearly the same size as the stock, as two or three scions of free-growing sorts be entered in the same graft; there are also these disadvantages, that the portion of the scion which is entered in the stock is useless, and consequently does not form that to time further new wood (whereas in budded stocks shoots occasionally spring from the buds of the scion, and after the first year it has taken, thus vesting the tree in perfect form, and handsome appearance), and also that grafted Roses, without great care, are liable to have their heads destroyed in very exposed situations, because it is generally below the long tongue of the graft, where it has a long hold of the stock, and where the wounds are well covered, it is liable to split itself in the cleft, and thus expose the end of the ligature, and [illegible] the [illegible] stock. After the first year, [illegible] we should be quite safe from [illegible] grafts once cannot be considered [illegible] satisfactory [illegible] to clean the garden [illegible] grafts, provided the [illegible] success, [illegible] [illegible] [illegible]

would draw far more heat from the bed (that is, ultimately from the hot lining) than none at all would: that is, it would facilitate its escape into the cold soil around the pit; and small gardeners will leave three cool linings, even when they put one fresh one. I must add a few words about the position of a pit:—Muck must be thrown together twice for most garden purposes, and must be wheeled into the garden. Muck once thrown together is fit for the pit, so that the mere supplying the hot muck to the pit entails no expense, where it is all required for the garden, and has not to be wheeled out again; but where there is a farm-yard, I would build the pit about 4 or 5 feet from the wall on the south side of it; and for the brickwork by the wall have a pair of large doors folding inwards, opposite the middle of the pit or pits. The common farm-labourer would through the gateway throw the muck at once to heat against the pit, and when it cooled, would give it its regular turning to heat again. On again cooling, the muck-carts would, through the opening, cart away the old muck, or part of it, for Grass, Turnips, Wheat, as the case might be, and fresh be thrown up as before. If thought necessary, two pits could be placed side by side, with an additional trench between them; there would be no expense at all here, and only the slight inconvenience of carting a few loads for Turnips from a distance instead of from a heap on the field, at a time when horse labour is in demand. Even this would not be the case when mucking Grass or for Wheat; also, it is clear that any gentleman having a couple of horses, or even one, might work a pit close to his stable in the same way, although not quite so free from trouble—that is, expense.—*G. U.*

Cabul Melons.—If Messrs. White and Co. had read attentively my remarks at p. 684, on Mr. Cuthill's advertisement, they would have seen that it was the Cabul Melon which I denied having distributed seeds of. I certainly had no intention of saying I had not supplied Messrs. White and Co. with the seeds of the Hoosainee in 1843. As many people seem to confound the above two Melons, perhaps a short explanation here may be of use. The Hoosainee Melon, of which Messrs. White and Co. had seeds (or, as Mr. Cuthill would call it, the Trentham Hoosainee), was raised here from the striped Hoosainee impregnated with the Ispahan. It is a large Melon, a free bearer, exquisite in flavour, and I believe inferior to scarcely any Melon in cultivation; and I feel not a little proud of its having been raised here. The Cabul Melon is one of recent introduction. The seeds were brought to England by the officers engaged in the Affghan war. It was first grown in this country, I believe, in 1843. With regard to its properties, it attains about the same size as the Hoosainee, is a very free grower, and bears abundantly. It is a handsome thickly netted Melon, with a very sweet melting flesh.—*G. Fleming, Trentham Hall.*

Strawberry-plants.—In the Calendar, p. 703, under the head Pineries and Vineries, directions are given for protecting from rain during the winter Strawberry-plants in pots or boxes, intended for forcing. "G. F." seems to think that rain is detrimental to the plants in pots. Under some circumstances I do not doubt its evil effects; but plants that have been properly prepared, and grown as they ought to have been previous to the arrival of the rains of autumn, require no such injurious treatment as boarding them in, which dries both leaves and roots. The best system that ever came under my observation, and which is adopted in many places where large quantities are forced, and that to the greatest perfection, is to keep them, from the time of being finally potted, plunged down to the rims of the pots in beds of sand—a south aspect is preferable; and where the ground will allow, the beds should have a fall of eighteen inches or two feet, but this must be regulated according to the length of the beds. By this method I have seen thousands of plants kept through the winter in fine health, and not half a dozen pots or plants damaged, either by rain or frost. If fine Strawberries are wanted, the potting off the plants should be completed early in August, so that the pots may be filled with roots before winter, as on that the success of forcing solely depends.—*Memet.*

Strawberries.—I herewith send you a sketch (full size), of a Keen's Seedling Strawberry, that was picked this morning with some others in an open bed in my father's garden in this town. Its being of an unusual size, viz. 7¼ inches in circumference, and 1¼ oz. in weight, of a handsome heart-shape, full coloured and flavoured, has induced me to thus notice it. I also beg to remark, that myself and a younger brother have had the entire management of the garden for some 10 or 12 years past, and we have succeeded in obtaining finer crops of Strawberries than most of our neighbours, which I attribute principally to not cutting off the leaves in the winter.—*J. W., Ashbridge, near Wells, Somerset.* [The drawing represented a very fine specimen.]

Gardening in Italy.—A friend who is on a tour in the north of Italy writes to me that since his last visit, twelve years since, he has found considerable improvement in the care taken by Italians of their gardens, in the construction of plant-houses, and especially in the beauty of the specimens cultivated. The great gardens of the Borromean Islands, of Monza, and of Padua, are much better kept and richer in species. The gardener of the Borromean Islands has succeeded in ripening the seeds of the Hydrangea hortensis by artificial impregnation, and by carefully cutting away all the large sterile flowers. The 9th vol. of De Candolle's "Prodromus" is almost ready, and the printing the 10th is to commence in January.—*

Pelargoniums.—The nurserymen's catalogues are now out, with abundance of flowers at a guinea and guinea a-piece. The descriptions abound as usual with splendid, matchless, indispensable, novel, magnificent, and words of dazzling import without end. Amateurs believed it all once, and with reason, for every season's advance was a stride. But now we wait a bit to see them in their true colours, and if we neither find them in letter A at Chiswick, nor in the seedling tent among the two-years-old, we shall put them down as good for nothing—unfit to exhibit—in fact, all that our note-books remind us too many of them are. Let nurserymen, therefore, do what they ought; respond to the liberality of the Society offering such liberal prizes, and serve the public and themselves by exhibiting the objects of their advertising praises at the Shows of the ensuing season. There is abundance of time, and nothing but want of merit can excuse their absence.—*A Purchaser.*

Morphology.—It is not a little amusing to notice the very awkward predicament in which a person places himself, by speaking in disparagement of a theory merely for the purpose of insulting those who have propounded it; but when we find that such an individual knows nothing about the theory itself, and is determined to learn nothing respecting it, then his remarks are too ridiculous to be either amusing or insulting to any excepting those who are as ignorant as himself. A striking exemplification of this came under my observation at the last meeting of the Regent's Park Gardeners' Society, in a discussion on Morphology. After much had been said, and several specimens exhibited in support of the claims of that science to the regard of horticulturists, and nothing intelligible proved against it, the last speaker, whose speech applied about as much to Morphology as it did to the planet Mercury, held up a well-formed Dahlia bloom, and asked if Morphology could produce that! It being understood that no one else was to speak on the subject, of course Morphologists had no opportunity of answering the question, which to me was cause of regret, because the same speaker on another occasion remarked that "The Dahlia was, in the recollection of many persons, a single flower; a row of five or six petals was all that could be seen. A large yellow eye, which delighted botanists, and the five, six, or seven single flat petals, possessing no other novelty than colour, were all that there was to admire." Now that the Dahlia has at least ten times as many petals as formerly, quilled instead of flat, and the "large yellow eye" has disappeared, a proof is given that a change of organs has taken place in it; to what cause, then, may we attribute the production of a double Dahlia? The same authority remarked that "The Dutch florists outran us in the production of double Dahlias; and while we were trying hard in this country to improve the flower, or, as botanists call it, spoil it, our Dutch brethren produced them fairly double." No doubt they did. But did our Dutch brethren set themselves to work in the first place to create a principle in the plant, that would admit of being wrought upon by artificial appliances, so as to change the structural formation and habit of its progeny to a wondrous, but as yet unknown extent? Or did they find that such a principle was inherent to the plant, ready to yield obedience to the skilful operations of man, for the gratification of his wishes, as in a thousand other instances? To assert the former is to make man a creator, to admit the latter is to admit the truth of that which harmonises with every known process through which matter passes from the simple elements to the highest compounds in organic nature, namely, the doctrine of Morphology. Whose opinion, then, savours the most of atheism—that of the Morphologist, who believes that the various organs of plants are convertible from one to another, and that they were made by nature susceptible of receiving modifications from external influences; or the anti-Morphologist, who ascribes every transformation in the vegetable kingdom to either chance or the art of man? Common sense will answer the question. I should not have made these remarks had I not been informed that four or five out of the 18 persons who voted against Mr. T. Moore's excellent motion for farther inquiry into the principles of Morphology were respectable gardeners. I trust that those persons will, for the sake of their own credit, and that of their Society, look a little more closely into the subject before they allow a blind scepticism again to associate them with parties whose object has always been to degrade the character of gardeners.—*W. Sherwood.* [If we had any influence with those persons in the Regent's Park Society who have shown themselves on this occasion men of intelligence, as many of them have, and very much to their credit, we should recommend them to separate from the blockheads with whom they are now associated. It is a pity that gardeners should waste their time in discussions with gardenasses; for thus we translate the terms *Eucepurus* and *Asinocepurus*, which distinguish the two great divisions admitted by Dr. James Bradley, in his amusing and instructive *Cepurologia*; a monograph which we may possibly republish some of these days, when we have collected a sufficient number of portraits to illustrate the numerous species distinguished by Bradley under each head. In the meanwhile, the following extract from one of the admirable articles in "Chambers's New Edinburgh Journal," should be committed to memory by all the parties concerned. "There is, on the other hand, a scepticism which does not strictly follow reason, but depends in a great measure upon ignorance, prejudice, self-conceit, and other unworthy feelings. We are apt to pronounce an unfavourable opinion of a new hypothesis without any examination, merely because it does not agree with ideas already established in our minds, when, if these ideas were rigidly tested, they might be found either erroneous, or far short of the full measure of the truth. It has been remarked by Adam Smith, as the cause of the feeling of wonder, that we lack something to connect our ordinary ideas with the new one presented to us: not seeing the whole chain of natural causes, we marvel. Now, marvelling is so agreeable to some minds as to form an inducement to their believing in novelties; while with others, of a more rigorous or cautious character, it presents only a ground of suspicion. Thus to great novel doctrines may be well so far; but if it be allowed to operate beyond the extent of a salutary caution, if we invariably shut our ears against new hypotheses, and persist in refusing them all opportunity of showing evidence in their own favour, merely because some weaker, wonder-loving persons receive them too readily, we obviously incur the risk of repressing the advance of truth. And it cannot be doubted that if those who receive all without discrimination are reprehensible, so also are those who reject all without discrimination. When their doing so is partly, as often happens, a result of mean personal feelings, it is certainly worthy of the strongest reprobation. It is impossible to imagine a sincere lover of truth acting in such a manner."

Seedling Cereus.—I herewith send a bloom of a seedling Cereus, raised in all probability from longissimus crossed by truncatus; the habit is decidedly pendulous, and it makes shoots of about a yard in length or more in one season, presenting a very handsome appearance. It is edged round the petals, and has a faint stripe down the middle of each petal. I may add that this flower was produced by severe ringing, by which mode I am inducing a number of seedlings to flower.—*Robert Errington.* [The bloom sent was very double, and measured fully 3 inches across. The colour was a delicate pink, with a slight tinge of purple, and having a darker stripe of pink up the centre of each petal. It is a very pretty and desirable variety.]

Foreign Correspondence.

Wellington, Port Nicholson, New Zealand, May 18th, 1844.—After a very fine passage I am happy to inform you that I and my family are all quite safe and well in New Zealand. You know that we originally intended to go to Nelson, to Captain Wakefield; but owing to his death, of which you will have heard by the time that this reaches you, we stopped at Wellington, where we all got good employment. I have been all day moving fruit-trees in Mr. Stokes's garden, which, although they were very badly arranged, and had only been planted eighteen months, had thrown out such roots, shoots, and fruit-buds, fully equal to those that had been planted five years in England. The climate beats all I ever heard of, and I have no doubt that it will in a short time be one of the finest countries in the whole world. The Wheat, even on the tops of the mountains, of which there are plenty round Port Nicholson, yields from 45 to 50 bushels per acre. The flour for the consumption of the settlers has been mostly supplied from Sydney and Valparaiso; but from the continual motion of a windmill which has lately been put up very close to some gardens which I have been working in, I consider in a very short time we shall be obliged to send some of our own New Zealand flour to the above-mentioned places to get rid of it. I was up at the valley of the Hutt, which is eight miles from Wellington, last week, to prune some fruit trees for Mr. Molesworth, one of the principal settlers here, and I slept at Burcham's, who has a very fine public house up there, and is doing extremely well: both he and his wife send their best respects to you. I am happy to inform you that they are both good friends to me and mine. My eldest daughter is stopping with them at the present time. I have taken a few acres in the valley of the Hutt, a short way above Burcham's, where I intend to establish a fruit garden and nursery; it is one of the sweetest spots that ever was beheld by the eyes of man. The beautiful River Hutt encloses one part of it, and the other is belted by a range of mountains, which are crowned with the most splendid trees from 50 to 150 feet high; and out of respect to you, my dear sir, I have called it "Loudon's Vale." I am afraid the Wellington gentlemen won't much fancy me leaving them; but I shall be obliged now and then to come and prune their trees for them. I have had capital success with Snow's Cucumber and Green-fleshed Melon. They seem to beat anything of the sort that was ever in this part of the world. We have had two Horticultural Shows since I have been here, at which I was one of the judges both times, and it would surprise you to see what the place produces, although as it were only four years old. I am glad to say that your friend Mr. Stokes, who desires to be kindly remembered to you, has carried away all the head prizes. I am collecting seeds of all the best New Zealand plants to send you, and by the next ship that sails from this port you may expect a small box of them. I have got on the table now before me a parcel of berries of the New Zealand Yew, which I am drying for you. You will please to write to Mr. Brooks, and remember me kindly to him, and tell him that I will send him a few things for his Arboretum, and also in course of time some New Zealand curiosities for his Museum. My family are all well satisfied with the country, and never express the least wish to return to England again. My eldest son is employed in a large store, and my youngest is in the Medical Hall with Dr. Dorset, the gentleman off whom I have taken the land, and who has been very kind to all my family, and indeed, I have met with nothing but kindness since our arrival here. My two daughters have been working at plaiting straws for bonnets, the first that has been done in the colony; it was exhibited at the Horticultural Show, and is greatly in demand by every one as

much superior to the most delicate imported kind. There is a beautiful native Ribes here which grows 6 or 8 feet high, on which I have budded both the Gooseberry and the Currant, both of which have taken well and are growing amazingly. I have budded also the Plum upon the White Thorn, which is also doing well. In fact, budding and grafting may be carried on here all the year round. All kinds of vegetables are cheaper here than in England, and bread, beef, &c. &c. I am sorry to inform you that high wages have caused a great deal of drunkenness and idleness in the colony. I am keeping a journal of the weather, which I will send to you by-and-by. We have had several earthquakes lately; one of them was a tremendous shock. There is a great deal of rain here in the winter season; but often we have as fine days as in the middle of summer. Our winter is just beginning now; but vegetables grow better in some instances in the winter than in summer. I shall embrace every opportunity of writing to you, and if a regular correspondence will be agreeable to you, I shall be most happy to keep it up. Owing to the unsettled state of first coming into a strange place I have not been able to gather much information worth putting in your Magazine; but I hope that when fully established on a piece of my own, I shall be able to send you some good botanical subjects worthy of insertion. I have sent upwards of 100 native plants to a gentleman in Van Diemen's Land, who has promised to send me fruit trees in return. Give my best respects to Mrs. London and Mr. Wakefield, to whom I shall write soon. I hope you will write me soon, and if you can inclose a little of the best Calceolaria seed from Mr. Snow in it I should feel greatly obliged to you, as there is not one single plant of it in the colony. I also a few Rose seeds, or in fact anything that you think is worth sending. Wishing you all health and happiness, I am, Sir, your obedient servant, *Wm. Tyrie.* [*Portion only of a letter addressed to the late J. C. Loudon, Esq., and kindly communicated by Mrs. Loudon.*]

Societies.

MEETING OF THE BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

(Continued from page 715.)

The Phosphorescence of Organic Bodies.—Although, at the previous meeting, this notice had been given of a Paper by Mr. Jos. Stevenson, on the Phosphorescence of Mosses, but the Paper had been lost, and he would merely refer to it as a subject of discussion.—Mr. Bowerbank stated that in company with Mr. Borrer, he had witnessed the peculiar luminosity of the Moss Bryum hornum.—Dr. Hankinson then gave a short account of the present state of our knowledge with regard to the various kinds of luminosity in plants, being the substance of some communications he had made to the *Gardeners' Chronicle* shortly after the meeting of the British Association at Cork. He remarked that he had often observed a luminosity to precede the aforesaid phenomenon, more particularly in the Fungi. He had also seen phosphorescence given out from the fermenting roots of Cassava.—Professor Henslow did not think that Meyen's theory of a slow combustion being the cause of the light could be admitted, because if it were, the light would be greatest where combustion was most active; and this was known to be contrary in the Museum, where there had been observed no light.—Professor Ansted repeated the statement he had made last year, that the light observed on highly-coloured flowers was an optical illusion. If it were a real light from combustion or phosphorescence, it would be seen best in the dark. But the luminosity referred to was best seen by daylight.

Mr. Bonnat Platteau, having observed that all the churchyards which he had seen in York were profusely covered with Marigolds, inquired if there was any superstition connected with this practice.—Mr. Schomburgk observed, that it was much more customary in Germany to deck the tombs of the dead with flowers than in this country, and there they planted the Marigold because it bloomed later than most plants.

A Paper was then read by Mr. T. Allis, on some of the rarer forms of Ferns in his own collection, and on their mode of cultivation, &c. The collection of Ferns which had been brought from Mr. Allis's house, and placed in a tent in the Museum grounds, contained several rare species of Ferns, and amongst others, Davies thrysophilla, Pteris serrulatella, Cibotium Billardiasi, Gymnosophaea chaerophylla, and a species of Didymochlæna.

"In the cultivation of ferns, I find [they] that are of constant character, they may be raised from sporules, but the characters remain unaltered, and the eye at once recognises them. Others, again, are subject to great alteration, as in some of the Adiants, which has hitherto only three sights, but I have plants of it with fronds of the same with the number of eights increased, and quite [illegible] from the allied species proximate [illegible] Polypodium Dryopteris and Phegopteris are [illegible] me; with me they retain their distinct characters [illegible] circumstances of growth. I have grown [illegible] a few feet of earth other; there [illegible] ter has from the first appearance of [illegible] greener and more chaffy stem, and [illegible] and I always find that it sends up [illegible] which are almost always barren. Those [illegible] retained growing in a peat bed in a cool garden, in the house, and when raised from seed, are in general [illegible] though liable to exceptions, I find that plants raised [illegible] other means of propagation them from seed, frequently [illegible] that those which grow by an extension of the [illegible] which propagate themselves by sending out young plants [illegible] extremity of the frond, as in the case with Asplenium bulbiferum, Davies, and Asplenium rhizophyllum, which produces a young plant near the under extremity of the frond, as Woodwardia radicans, or which have young plants springing from the upper surface of the frond, as in the case with Asplenium viviparum. On the other hand, Asplenium bulbiferum is an exception to this rule; this plant bears an ample crop of little bulbs, which fall off and germinate freely. Also the little black tubers from the Tigua Lilac, which, at the same time, the frond is covered on the back of [illegible] with innumerable [illegible] and Woodwardia radicans [illegible] in her conclusion: "Another [illegible] we have [illegible] grows under wood, in [illegible] and it wandered over a [illegible] and it produced [illegible] round. [illegible] the [illegible] almost every [illegible] yards of almost every [illegible] botanists to name [illegible] offering a prize in this [illegible] which have no recognisable [illegible] as its proper one. I planted a specimen of Gymnogramma [illegible] Botanical Garden by Mr. Henderson, gardener to Earl Fitzwilliam, at Milton; it is different from any previously cultivated species. I also have a plant of my own, which appears to be, and I have no doubt it is, a Pteris, unlike any Pteris I have possessed, of that I recollect to have seen. From its appearance, I should take it to be a cross between Pteris hirta and flexuosa, but unfortunately the latter beautiful plant has never fructified with me. I find a great difference in the frequency with which the Ferns propagate themselves spontaneously from seed; the genus Pteris is among the most frequent, and springs up in various species in all directions. Blechnum, Doodia, and Gymnogramma also spring up freely, and some species of Diplazium, Chellanthes, and Dicksonia frequently occur. Of Polypodiums I have had very fine seedlings; the same may be said of exotic Aspidiums; and only a few Asplenium. I have this year adopted what I believe to be a new method in raising Ferns from seed, and, as far as I can at present judge, with complete success. The plan I have adopted is to obtain a block of peat turf, such as is sold in York for the purpose of lighting fires; that I thoroughly soak in water, and then place in a Cucumber-frame. On these turfs I sow the seed, and, keeping them shaded from the sun, I have a good crop of plants; but I am yet unable to determine whether they will prove to be the species sown, three of which have not before been, as I believe, cultivated in England; the species are Polypodium membranæfolium, Asplenium variæfolium, and Alsophila excelsa, all from Norfolk Island. The seed of Ferns is so volatile, and so fills the air, that though I have used a good deal of care to prevent seed from my pinery finding its way to my seed-beds, I am as yet unable to assure myself of possessing the new species. In the work on Australia, from the pen of my friend and relative, James Backhouse, there is notice of the occurrence of many species of Ferns; and from his observations on the native habits and habitats of several species, I have derived great advantage, especially so by planting a considerable number on decayed trunks of trees, where they grow with a vigour such as I never before experienced: a particular instance is the beautiful Asplenium nidus, a plant I have had for years, but which was always in so feeble and rickety a state, that it was scarcely able to maintain existence, and I had sent it out to nurse, under the care of our experienced curator, in the Orchidaceous stove in these premises; still it never put on a healthy appearance till I planted it in part of the stump of an old Willow, where it now flourishes in the greatest vigour, and is putting forth its fertile fronds."

After the reading of this Paper, the President and members of the Section repaired to the tent in which Mr. Allis's collection was placed, where he gave a further account of some of the more remarkable species.—*L. E.*

(*To be continued.*)

COUNTRY SHOW.

Staines Celery Show, Oct. 22.—At this Exhibition some excellent samples of Celery were produced, and several prizes were awarded; but we have only been furnished with a list of awards, without the sorts of Celery being specified for which these awards were given.

Reviews.

Elements of Agricultural Chemistry. By Sir H. Davy, Bart. A New Edition, with Instructions for the Analysis of Soils, and Copious Notes. By John Shier. 8vo. Glasgow. 1844.

This book is a reprint of Davy's well-known Lectures, delivered before the Board of Agriculture, with a commentary of notes by Mr. Shier. The Editor has evidently taken great pains to collect as much useful information as he could, and the notes are for the most part clear and intelligible. It is, however, not very evident for what class of readers the book is intended. For chemical students, the details are frequently very meagre and incomplete; if, on the other hand, it is intended for farmers, we fear that a great deal of it will be quite unintelligible. All use of chemical symbols must be avoided in books intended for farmers, if it is desired that they should understand what they read.

Garden Memoranda.

Chatsworth.—The works at this seat of magnificence are proceeding with unabated activity. During the summer two new fountains have been set in action, of which one, called the Emperor, from a single jet throws a column of water nearly 300 feet high. The force of this fountain may be imagined when we state, that in an hour it lowers an acre of water to the depth of a foot. The other, quite unique in design, consists of several jets, whose copious streams rise and fall alternately, producing the appearance of dancing water, and an effect perfectly enchanting. In addition to these, huge masses of rock are collecting and forming into a rockwork, the like of which has never before been seen. Some of these masses weigh upwards of 370 tons. In one place they are put together in exact imitation of the Strid—a rocky stream at Bolton Abbey—and when completed will form a wild mountain scenery, [illegible] 800 feet long, with banks full 30 feet high. [illegible] works are necessary at Chatsworth, where another [illegible] would be lost amidst the grandeur of the place. [illegible] Conservatory now contains some more beautiful specimens of Camine, which had themselves to [illegible] than if they were [illegible] [illegible] of rock work, [illegible] Eucalyptus speciosa was in [illegible] here for the first time we believe that in [illegible] fronds of [illegible] have been [illegible] in England. [illegible] will [illegible] know what [illegible] may be, should visit the gardens near Eaton's residence. They will there find it with a [illegible] stem, 10 feet high, from the top of which spreads an umbrella of graceful fronds, each of which is terminated by long clusters of its beautiful crimson flowers. In the same part of the grounds will be found an Orchidaceous house, crowded with plants in rude health, and tastefully arranged with trunks of trees, &c., so as to form a grove; and near them a most singular specimen, somewhat coral-like leafless plant, covered with beautiful blossoms of a golden Lichen, which appears to be Usnea barbata. This curious specimen, which has not been recognised as yet by any botanist, was sent to his Grace the Duke of Devonshire, from one of the most N.W. portion the west of Tropical [illegible].

Tolpis virgata, Gaudich.—The splendid Grass, Gynerium argenteum, which, if it all known, is extremely rare in British collections, is now in full flower in these gardens, where it has stood, without any protection, during the last three winters. Mr. Tweedie, who sent the seeds from Buenos Ayres, after stating the dimensions to which it attains on the extensive pampas of that country, further adds, that "it is the most showy plant of any class." This is no doubt saying rather much for it, though it is certainly a splendid object as it occurs here at present, with the culm rising to a height of nearly 10 feet. The flowering panicles are 18 inches long, compact, and well-formed, both in shape and apparent texture resembling the white feathers worn in military caps.—*D. M.*

Miscellaneous.

Transplanting Trees.—When all was clear and the tree ready for transplanting, it was raised out of the hole in which it grew, by bringing the head down on one side by means of ropes and shovelling earth under the bottom of the ball and roots, then doing the same on the opposite side, again filling in with earth and repeating this on alternate sides until the bottom of the ball was level with the surface of the ground. In the next place care was taken to choose the flat or hollow side of the tree to rest upon the bolster when lowered; for if the tree shifts or turns during its carriage, the bark will be injured and the head and roots broken. The wheels were then put in such a position that the top of the bolster was close to the ball of earth at the foot of the tree, the pole or beam raised, and the ring and top fastened with flat rope to the body of the tree, the latter having been previously wrapped with matting to keep the ring from bruising the bark. The bottom of the tree was well secured to the bolster by ropes and chains passing under the butt, the bark being again protected by means of matting, and the tree then forced down upon the machine with ropes and pulleys, and so made ready for removal. The horses were now yoked by chains to the axle of the machine, and the tree drawn out ready for [illegible]; but as the fresh earth was of course too soft to bear the pressure of the wheels, cordwood was placed under them until they came on firm ground. It is absolutely necessary that the roots of the tree should be a little heavier than the head, and this will always be the case if the above plan is carried out, except in very light sandy soils. Equilibrium was maintained by one or more men who acted as balancers in the top of the tree, so that by shifting their situation as occasion required, the whole weight was thrown upon the wheels, and the roots and branches both preserved from injury. The tree was guided by the directory who had two lines fastened to the bole of the tree, a few feet above the top of the pole of the machine, and carried between and to the extremity of the branches where he took his station, and thus was enabled to guide the machine with the greatest accuracy. On arriving at the side of the pit, which had been previously prepared for the reception of the tree (the best side of the tree being placed to front the coach road), the wheels of the machine were gradually lowered down the inclined plane, cut for the purpose from the surface of the ground to the level of the pit; the tree was then placed in the centre of the pit, set upright, the machine removed, and the roots carefully adjusted while the soil was thrown in, watered and rammed around them until the tree was well fixed, the long roots being so placed and worked up and down that they acted as a stay in keeping the tree upright. To the roots of each large tree two cubic yards of good earth and lime compost, and one of sifted cow-house were added, and the same mixture for the smaller trees in proportion. In every case care was taken not to plant the tree deeper than it grew before. The situation allowing water from a brook to be turned over the ground around the trees, it was well soaked once a week during the first spring and summer, every nine days the second year, and every fortnight the third year; it was also covered with moss, straw, &c., for the same period to protect the young roots from frost in winter and drought in summer. Not a sprig was intentionally taken off the heads of any of the trees, nor was any one of them propped or secured with ropes when first transplanted, although the situation is much exposed to the south-west. Every tree removed from Mr. H. Stewart's park has lived, and this, no doubt, principally owing to the manner and regular watering given them, the method has succeeded so well that it will be seen by a comparison made with two Oaks trees now growing in the field from which the first four were removed in 1832. One No. 1 removed has exceeded No. 1 moved in 1833, and No. 2 moved was 70 years old at the time of its removal, has increased in girth within a quarter of an inch of No. 4 not removed; these trees are very similar in appearance. This result is the more extraordinary, as no large tree increases in size for the first two years after its removal; therefore these trees have increased as much in nine years as these not removed in eleven years. It is generally supposed that the cost of removing large trees must be great, but this is shown

not to be the case by the fact that the first four Oaks were removed in 1832 (my first attempt), at an expense of 8*l.*; the remaining 16 Oak and Elm, with six sorts of wood and large Apple trees, for 23*l.* 2*s.*, being about 21*s.* per tree. The best and cheapest plan is to prepare the trees during the winter, three or at least two years before transplanting, by cutting off all the roots (except two or three of the largest on the south-west side, to be left to stays when the tree is removed) at 4 to 5 feet from the bole of the tree, making a trench 2½ feet wide and as deep as the depth of the roots, at that distance from the stem, all round the tree. The trench is then to be filled with the best obtainable mould, mixed with a little lime, and covered over with moss, straw, &c. If the tree be healthy, in two or three years the whole of the trench will be filled with fine fibrous roots; and care being taken not to injure these, the tree may then be removed with the certainty of growing if carefully pitched with the roots extended as above described.

The following are the particulars of the great Sycamore, mentioned by Thomas Newport, Montgomeryshire, published by Thomas Martyn, in 1814. "The girth, measured and sold for more than 400*l.* — The body or bole of the tree was only 10 feet long, and measured 490 feet; there were in the limbs twelve saw pipes, one of which made a rudder for a Dutch ship, and the whole of the young timber in the tree was 48 loads and 33 feet, of 50 feet to the load. The bark was only about 4 tons.—*R. W. Purghes, Plaston, near Chipsion, March, 1844.*

TREES TRANSPLANTED, MARCH, 1832.

No.	Sort of Tree.	REMARKS WHEN TRANSPLANTED.	Age.	Girth at 4 ft. from ground. 1832.	1843.	Increase in 9 years.	Height to tip of Spray. 1832.	1843.	
				Inches	Inches	Inches	feet.	feet.	ft.
1	Oak	Good head, well rooted, handsome tree	48	33½	45½	12	29	34	5
2	Ditto	Rather small head and roots. The top shoots were so much injured by frost in May, 1833, that 2 feet were cut away	60	44	54	10	40	45	5
3	Ditto	Large spreading head, no roots on this side. This tree grew close upon the side of a deep hollow lane	70	47	62½	15½	38	44	6
4	Ditto	Good head, well rooted, handsome tree	50	35½	44½	9	26	34	8
		N.B.—It is singular that Nos 1 and 4 bore acorns in 1834, which were planted but did not vegetate.							
		TRANSPLANTED, MARCH, 1834.				Increase in 7 years.			
5	Ditto	Kind, large head, very difficult to get out; nearly all the roots broken off	55	42½	46½	3	35	39	4
6	Ditto	Middling sized head, well rooted	50	32½	39½	6	32	37	5
7	Ditto	Kind, large upright head, very difficult to get out; loaded thrice; nearly all the roots broken off, and scarcely any soil left on the ball	65	50½	55½	5	42	45	3
8	Ditto	Prepared 1833; middling head, good bark, very good roots, from 1 to 2 feet long, since prepared	45	36	42½	6½	28	35	7
9	Ditto	Prepared 1833; middling head, good bark, very good roots, from 1 to 2 feet long, since prepared	30	29	36	7	21	28	7
10	Ditto	Fast growing, bark white, slender head, roots small and few, grew in a very obstinate situation with No. 15. The bark would have stripped when removed	40	31	37½	6½	26	32	6
11	Ditto	Bark very rough, kind head, all the roots cut round at 4½ feet from the stem when transplanted	35	25	34	9	24	32	8
12	Ditto	Rough bark, good head and roots, but a slow-growing tree	50	36½	44½	7½	24	31	7
13	Ditto	Bark thin, handsome sugar-loaf head, very badly rooted	55	38	43	5	38	40	2
14	Ditto	Bark middling, very kind head, well rooted on one side	52	36½	46½	9½	43	46	3
15	Ditto	White bark, middling head, middling rooted, fellow to No. 10	30	22½	29½	6	25	32	7
16	Ditto	Rough bark, well rooted, middling head	45	26	31½	5½	26	37	9
17	Ditto	Bark good, very good roots, large, kind, round head	20	20½	20	8½	15	19	4
18	Ditto	White bark, middling roots, kind head	30	18½	28½	9½	19	27	8
19	Ditto	Bark good, ranking ivy tree (grew under 7), roots cut round as 11 (died the second year)	40	22	—	—	—	—	—
20	Elm	Kind tree, very badly rooted, nearly in leaf when moved	25	26	40	14	25	33	8
21	Wytch Elm	Kind, large head, very good roots, not forward in leaf	25	34	43½	9½	24	31	7
		The greater part of the Oaks transplanted in 1834 were growing in Coppice Woods and Plantations, upon very sidelong ground, which made it difficult to load them, and would not have been transplanted if better subjects could have been found.							

TREES GROWING UPON BIGSWEAR ESTATE NOT TRANSPLANTED. (HEIGHTS NOT TAKEN.)

No.	Sort of Tree.	REMARKS.	Age.	Girth at 4 feet from ground. 1832	1843	Increase in 11 years.
				Inches	Inches	Inches
1	Oak	Good bark, small head	60	44½	55	10½
2	Ditto	Good bark, very large handsome head	65	55½	71	15½
		These Trees are growing in the same field from whence the first four transplanted Trees were taken.				
3	Ditto	This tree grew from a stake put in the hedge, large handsome head	40	54½	65½	10½
4	Ditto	Grows upon the high bank of a brook, handsome head; some roots were cut off in 1832	70	56½	62	5½
5	Ditto	Tall, upright, fast-growing tree	50	40	52	12
6	Ditto	Tall, fast-growing, kind tree	40	26	38	12
7	Ditto	Ballard, cropped about 20 years	100	70½	75	4½
8	Ditto	Fine, handsome, large headed tree	90	100	105	5
9	Ditto	Remarkably handsome, large headed tree	90	107½	116	8½
10	Ditto	Considered about twenty years ago, was then ten years old	20	5½	17½	12½
		The first five Trees are growing in the same meadow as the transplanted trees, and the others in the meadow adjoining.				
1	Poplar	Black Italian. These Trees were transplanted in 1839, then five years old, by the	15	70	87½	27½

4	Ditto		—	94	103	9
5	Ditto	Near to Pilstone.	—	94	103	9
6	Ditto	30 yards from the road. This tree was prepared for removal Feb., 1843, but unseen. Decided protection in Bigswear. Could not remove for following two years, and now [illegible]	—	74	83	9

—*From "Transactions of the Monmouth Farmers' Club."*

Large Potatoes.—There is at present to be seen in the shop of Mr. J. Ramsay, High-street, Forfar, a Red Potatoes of the Blucher red kind, weighing full 3 lbs. (one of them weighs 2 lbs. 3 oz.), all grown on this stem, in the garden of A. Donald, Muir of Lowrie, parish of Dunnichen.—*Montrose, Arbroath, and Brechin Review.*

CALENDAR OF OPERATIONS.

For the ensuing Week.

I.—HOTHOUSE, CONSERVATORIES, &c.

By the end of October stove plants, not winter growers, should be thoroughly ripe, and therefore require less heat than they had for the last two months. A rather high degree of heat, say 70° by night, and three or four degrees more by day, will be necessary for the next six weeks; after that will be sufficient to carry on the process of fine weather early in spring. If this can in this house could be kept at pure all the winter, the conservatory although the winter, the plants would require very little fire-heat, but with strong sun heat this cannot be done, and the air must be changed as much as the weather will permit. Currents of cold air, however, are injurious to stove plants, and it is better to open all the ventilators, doors, &c. for half an hour on a fine day, than to give three or four inches of air on a small scale. One of the most powerful winter-flowering stove plants is Aeschynanthus pulcherrima. It is a plant of the easiest culture, and flowers on the top of the shoots, and, like all plants with this habit, it should be often stopped when young, to induce a quantity of the shoots, as the more shoots the more flowers. Grown standard high on Acacia stocks, its near relative, it would form a splendid object in a short time.

Conservatory.—Ipomœa tyrianthina and Tacsonia pinnatistipula are two beautiful climbers for this house, requiring exactly the same treatment, but rather difficult to manage in modern conservatories as they are impatient of confinement and do not like much sunshine. The best way to treat them is to plant them in the front border, and to have the tops taken out to the roof and through the rafters; but this style is inadmissible in most modern conservatories. Some part of an architectural assemblage in fact, such things should be planted near the doors, or flowers of corridors, or against the back wall, in either case where they can be kept partially shaded, and never allowed to get out of the house. They are good subjects for elevated shrubberies, where they may ramble at ease. However, they are thirsty plants, and apt to draw in spiders, &c. where they are growing, some people advise their being kept rather dry, but a free circulation of water and a free circulation of air are the two things they delight in. Try them, however, in a slope, and where hoses can be used, and you will find that half the usual quantity of water necessary for them if they will keep in bloom longer, and do not suffer from dryness. The reason for this is well explained in the opening article of last week.

Pelargoniums and Fuchsias would strongly remonstrate if we were to name a third of the plants that are all the winter forcing, so much having been already said about them. I always look at the report of Chiswick Gardens, which is for the last fortnight that are on sale in winter, which is a good index to what is done in this way round London. I am curious about how they manage the Bignonia velutina, so as to have it in succession as long and so much out of its season. Will any kind reader supply the information?—*D. B. S.*

II.—FLOWER-GARDEN AND SHRUBBERIES.

Out-door Department.

The business of this department is now in a great measure confined to the clearing up of leaves, weeds, and other extraneous matters, and making the lawns, &c., look as tidy as the season will admit of. If the bulbs are planted—and if they are not, no time should be lost in getting them into the ground—those beds which are unoccupied may receive their winter digging, or trench necessary; winter trenching, taking care, if there is a lawn, to throw it as much as possible to the action of the atmosphere. While, however, you dig the beds, avoid touching the shrubbery borders, for though custom, which too frequently makes us commit sad blunders, may say they look much better after being dug, depend upon it plants do not grow any faster for being annually root pruned, and such is the effect of annual digging. Worms are now very troublesome, especially in wet weather, when it is difficult to clear their casts away, but they might easily be materially thinned by watering the ground with fresh lime-water, or with water containing corrosive sublimate, though in the latter case they are merely driven out of the ground, and require to be gathered up by hand, and afterwards destroyed. Corrosive sublimate is very quickly brought into a liquid state by mixing it with spirits of salts.—*W. F. A.*

III.—FLOWER-GARDEN AND PLEASURE GROUNDS.

Auriculas.—If in their frame (unprotected) should be protected from damp, and especially prevent fogs finding its way through the glass of the frame, and attacking the tender hearts. In order to prevent this, the tops of the glass ought to be pitched. If pots get sodden with rain, and continue wet for a few days, the destruction of the plant is almost inevitable.—*Polyanthuses.*—We have them in full flower, it is not, however, advisable to permit this, or to allow the plant to weaken itself by blooming at unseasonable periods. Newly-planted cuttings, when small, are apt to be dragged out of the ground by the earth-worms; the borders should therefore be looked over and the plants taken fresh root. *Dahlias.*—In many parts of the country have been cut off by the late frosts; where that is the case they should be taken up while they still start quite at this season, and after being tolerably well dried in the sun have been numbered and attached to the roots with strong packing wax, they may be hung up for a few days in a dry airy shed, preparatory to cutting off the stems and storing the roots. Where they have escaped, which in the early parts of the kingdom, every precaution should be taken (by propping the stems and roots) to prevent injury in the event of a sudden change of weather. *Tulips.*—We have taken advantage of the late fine dry weather, and planted our Tulips, and fortunately the bother they are in now the better. Bulbs and tubers mentioned in Articles, in late Nos. of the *Chronicle*, on the Formation of Beds, Planting, &c.; the information in there given may be safely acted on. *Carnations.*—Get in your stock as quickly as possible. We must enter our protest against propagating these varieties from a distance, after the first week in November, unless the layers are extremely healthy and well rooted.—*W. F. A.*

IV.—PINERIES, VINERIES, &c.

Pineries.—Where plants are swelling their fruit the temperature need not now exceed 60° at night. It should not, however, be allowed to fall below 55°. Such structures may be raised to 70° by fire-heat, by shutting up the air early, on fine clear days, and whenever a small portion of air can be given, it will be advantageous to open the top ventilators a little, but for 30 minutes or so, about mid-day. Now that oak and other tree leaves can be had, in quantity, between the autumnal leaves and half dung for lining the pits planted, is preferable to what is done in this way round London. I am curious about how they manage the Bignonia velutina, so as to have it in succession as long and so much out of its season. Will any kind reader supply the information?—*D. B. S.*

Vineries.—Remove all fading leaves from the Vines on which fruit is hanging, and keep the house free from everything likely to create mould or damp. When there is any appearance of frost in the evenings, a sufficient fire be made to keep the temperature up to about 40° during the night.

Peach Houses.—If the fruit is not still in the Peach houses it is time to put them on again giving them all the air possible. If the trees in the late house have not yet ripened the wood sufficiently, continue to assist them by making slight fires during the day, giving at the same time plenty of air.

Fig House.—The pruning of Fig trees, like that of Peaches, is performed in the summer and autumn. Let whatever winter pruning required be done as soon as the leaves fade. Wash the whole of the trees over afterwards with soap and water till they are perfectly clean, and then mix soft soap and sulphur with warm water, in the proportions of half an ounce of soft soap and half an ounce of sulphur to a pint of water, and let the whole of the trees be well rubbed with the mixture. Put the house into a state of thorough repair and cleanliness, and then fill up the trees.

Strawberries.—If these have not been put into their winter quarters no time should be lost in getting them in, as the roots will suffer from too much wet.—*G. B.*

V.—KITCHEN AND FRUIT GARDEN.

Peaches and Apricots.—Remove all green laterals, that the growth of the trees may be checked, and with a new birch broom gently switch off the matured leaves, taking care not to injure the buds, repeating the operation at short intervals, so that the young wood may be ripened by exposure. To effect this still further, cut away small twigs that will not be wanted, and loosen from the wall wood shoots intended for bearing next season as soon as convenient. Where unfortunately the leaves are still green and abundant, no time should be lost in going over the trees, and shutting all the stronger leaves in two. As no great nicety is required, a man will soon go over a wall, by catching the leaves between his knife and thumb. This will tend to check luxuriance, and hasten the maturation of the wood, without rendering the shoots either shrivelled, or the

receptacles of unelaborated sap, which, to break into [illegible] rankes, which is most conducive to the health, must necessarily be had either by indiscriminate pruning, cutting, or [illegible] deprivation of leaves.

Cucumbers.—There is no difficulty in growing these at this season, or during the winter, provided heated atmosphere, even a good fire, that will not allow the escape of smoke or deleterious gases, be at hand to change the air, to a small extent, at pleasure, "I say they cannot grow in a dwelling-house, or pigeon-holed and fired, having only room for growing plants alone; but without having abundance of dung, &c., it would be folly to attempt it. [illegible] would be [illegible] common frames; but such should be constructed in the manner as to prevent the ingress of steam, and to keep the atmosphere in a healthy state. Those who still have their fancy fixed on frames, and their minds blessed by surveying the hot-water tough chopped dung, and their [illegible] with lime, which may be painted over with sulphur [illegible] spider. Those who are particularly [illegible] will obtain them most economically [illegible] narrow house, or pasture, as all the work of attendance can then be done from the inside. The simplest system of heating by hot water will be the best, provided it is [illegible] of bottom and atmospheric heat. *Asparagus, Sea-kale, and Rhubarb.*—Preparations must now be made for forcing those where they are wanted for use early. Those in the open ground, if better than a late Melon-bed [illegible] and [illegible] heat, or a slight hot-bed may be made use of to [illegible] at pleasure, if it should prove too strong. Place the plants as thickly as possible, and so keep the [illegible] to allow the shoots to grow the requisite length, and then [illegible] green or blanched as pleasure, unless the weather should be very severe. The best method to adopt in the latter is to form a small hotbed in any convenient place; take up a number of roots, place them on it, with a little soil or any sort amongst them, and defend from the weather and light, by any old boards that can be obtained. Where a [illegible] is at work, a better place could not be found. *Strawberries.*—Forced fruits and roots, plant [illegible] and Fastus in frames, young ones out of doors to afford the winter. *Seleral Large Cauliflower* from hand, and young plants from [illegible] Match and dig about Globe Artichokes, [illegible] and [illegible] Asparagus for the winter, through supposing [illegible] to be attended to, remove all decaying vegetables, but take nothing to the [illegible] that may do for food, and so far as the [illegible] leaves will [illegible] give every plant a [illegible]

KAIL-YARD, OR COTTAGER'S GARDEN.

The leaves bring now for the most part on fruit trees, and the ground admonishes [illegible] the late hands, the Cottager, with every prospect of success, may [illegible] may soon be busy with his [illegible] implements. [illegible] the best season for planting all kinds of fruit trees, if the weather is open and tolerably dry, and, moreover, if any new kinds are wanted from the nurseries, there is [illegible] better chance of having them good than [illegible] have been [illegible] planted many [illegible] The following list may be useful to those who are about to form a new garden, or add to their present collection. Of Apples, I would recommend as decided favourites, [illegible] viz. Early Harvest, ripe in August; Keswick Codlin, ripe in September; Court of Wick, from October to March; Old Nonpareil, from October to May; Golden Pippin, November to January; and Dredge Kingston, from December to April. Sorts for [illegible] Early Harvest, Apple Jersey, Bedfordshire Foundling, from September to March; Royal Russet, from November to May; Lemon Pippin, from November to February; and Wormsley Pippin, from September to January. Of Plums, I would recommend as [illegible] Orleans, Coe's Golden Drop, Early Red, Vine, Sour, and Shropshire Damson. Of the [illegible] excellent for preserving. The [illegible] should be planted [illegible] trees should be well [illegible] manure [illegible] are then [illegible] thoroughly mixed with the soil. Look over Cauliflower and Lettuce plants for slugs. If they are [illegible] sprinkle some hot lime [illegible] the plants [illegible] and destroy the [illegible] Stop [illegible] when wet, [illegible] not [illegible] plants in pots. They should be kept rather on the dry side during winter, never water them except when they absolutely require it, and then give them a good soaking. [illegible]

Notices to Correspondents.

BIGNONIA JASMINOIDES.—[illegible] plant under the name, [illegible] beauty referred to; the other flowers [illegible] a small pot. But why grow this poor [illegible] other is all that can be wished for? [illegible]

CUCUMBERS.—*A Beginner.*—Soil composed [illegible] light rich mould from an old pasture, one-eighth vegetable mould, and one-eighth rotten dung, will produce [illegible] in abundance. Keep the temperature [illegible] at night, allowing [illegible] air in [illegible] night with mats, but they should never be removed by [illegible] in order to admit all the light possible to the plants, [illegible] is very essential to their welfare.

GRAPES.—*Didi.*—The [illegible] Tokay is the [illegible] Lombardy; bunches very large. The [illegible] the bunches being small.

HEATING.—*F. R.*—An Arnott stove, well [illegible], will heat [illegible] [illegible] [illegible]

FARM.—Wanted to Purchase, A FARM, of 200*l.* to 400*l.* a-year rental; to abut on a county town.—Address, by letter, stating price, distance from railway, and place, to E., *Gardeners' Chronicle* Office, 5, Upper Wellington-street, Covent-garden, London.

TO COLONISTS.—EMIGRANTS.—MARY WEDLAKE, widow of the late THOMAS WEDLAKE, at 114, Fenchurch-street, London, manufacturer and others that she continues to manufacture those agricultural implements for which her late husband was extensively patronised by the Settlers in South Australia, Van Diemen's Land, Swan River, New Zealand, and other British Colonies. The following articles made in a first-rate manner, are kept on sale at the London Warehouse:—
Patent Hay-making Machines,
Dressing Machines,
Patent Chaff-cutting Machines,
Oil-cake Crushers
Double action Bundle cutters,
Railway Waggons.
Please to be particular in the address, MARY WEDLAKE, 114, Fenchurch-street, London.

The Agricultural Gazette.

SATURDAY, NOVEMBER 2, 1844.

MEETINGS FOR THE EVEN FOLLOWING WEEK.
Wednesday, North Lancashire Agricultural Society.
Thursday, Newry Agricultural Inst. for Ireland.
Friday, Wakefield Agricultural Society of England.
Saturday, Newry Agricultural Inst. for Ireland.

Much as England owes of her prosperity to her mineral wealth, the value of her SUBTERRANEAN AGRICULTURE is scarcely less. The means which these afford of increasing the fertility of the surface, and of furnishing profitable employment for the agricultural labourer, have hitherto been too much neglected. Widely as the geologist knows these to be distributed, and highly as he appreciates them, he sees agricultural practice availing itself of them only here and there. Wherever this is done, the result is such as to confirm his conviction of the advantages to be derived from their more extensive development; but in these operations the same want of system and of guidance by general principles is observable, which pervades everything connected with agricultural practice.

Perhaps few parts of the geological series furnish a better illustration of their value than the rocks of the cretaceous system. Our geological maps afford a very inadequate notion of the extent to which these rocks are applicable to the improvement of the surface. They exhibit only the stratified or unstratified rock which in each locality is nearest to the surface, disregarding, and supposing to be wholly removed, that loose covering (also the usual deposits of the northern drift) which is of the greatest importance to the agriculturist, and often of great thickness. We see laid down on these maps a main ridge of chalk hills extending in a north-east direction from the southern part of Dorsetshire to the coast of Yorkshire, and sending off two branches, which, under the name of the North and South Downs, stretch eastward to the Isle of Thanet and Beachy Head. But the agricultural influence of the chalk, or the influence which it is capable of exercising, extends far beyond these limits. Through all that triangular space bounded on the west by the curved line extending from Beaminster to Flamborough Head, and on the east and south by the German Ocean and the English Channel, the chalk, where it does not rise to the surface, constitutes (with an exception which will be noticed presently) the subjacent stratum, and is covered by sands, gravels, and clays of later formation. From the rise of the strata towards the west, the beds of the gault and greensand, which constitute the lower members of the cretaceous series, emerge from beneath the chalk on the western side of the main line of chalk hills, and form a narrow parallel band of argillaceous and arenaceous strata at their base. The excepted area within which the chalk does not form the substratum is the district of the Weald of Kent, Sussex, and Surrey. There, a movement of elevation, having an east and west direction, has broken up the cretaceous rocks, and brought to the surface the beds of clay and sand below them. The latter occupy the centre of the Weald of Kent (the portion, the former thinks this central ridge in two parallel bands, between which and the North and South Downs the gault and the greensand occupy the same relative position at the base of those hills which they occupy at the base of the western line of chalk hills. These ranges of chalk hills are anything but fertile. Large portions of them are in the state of sheep-walk—the calcareous rock being covered only by a few inches of light vegetable mould, which supports a short though sweet herbage; and the crops produced on the arable portions are raised at the expense of large dressings, by means of the sheep fed on them in the day and folded on the fallows at night. The purer sand and clay strata of the lower greensand, the firestone, marl, and Weald clay, afford likewise unproductive soils, to be prized by the farmer. The gault consists of a mixture of clay and calcareous matter, highly productive, but, from its tenacity, difficult to work; while in portions of the upper greensand the addition of a large admixture of siliceous matter to these two combs produces a deep rich friable loam, capable of growing every description of crop. Thus we see that nought by Nature here is lavished in vain, but by the admixture of earths which in their separate state are barren and worthless, we have in the introduction of portions of the gault, clay, and gravel from the great triangular area before-mentioned the means of improvement by the application of chalk and clay as hitherto also the chalk is much used and with advantage as a manure in the county of Sussex. In its unburned state it has long been employed with great success in a few districts of limited extent. To the sands, gravels, and chalk of Norfolk, under the name of marl, and in a state of intimate tenacity and calcareous matter.

The marl is the solid chalk, the clay is the transported fragmentary chalk mixed with a variable proportion of clay or loam. Both are generally found at moderate depths beneath the surface of the land to which they are applied. To those parts of the district where the covering is too deep to enable the farmer to avail himself of them, they are conveyed by water from pits on the banks of the navigable rivers. A cubic yard of *rincallon*, as the overlying sand and gravel is called, is frequently removed in order to obtain a cubic yard of chalk or chalk rubble. In the "marl" pit of a farmer we have seen the chalk covered by sand and gravel 13 feet deep, and worked to no greater depth, though it was stated by him that the quality improved with the depth. In the lime-works near Norwich, the covering is 40 to 60 feet deep, the depth to which the chalk is worked not more than 60 feet. From the numerous pipes which penetrate the chalk, a very large proportion of it is too much weathered, and too much mixed with the sand and clay which fill these pipes, to be burned for lime, and is put into barges for the use of farmers at a distance. The chalk of Kent is applied to the London clay of the Isle of Sheppy, which it improves mechanically, by rendering the soil more friable, and chemically, by imparting calcareous matter with probably a small portion of phosphoric acid, and by neutralising, with formation of sulphate of lime, the injurious salts of iron which that clay contains, and which results from the decomposition of the iron pyrites so abundant in it. On other portions of the London clay, constituting the surface of parts of Essex and Suffolk, the farmers have long and extensively used for the same purpose the chalk of Kent, conveyed to them by water. All this shows over how extensive a tract of country chalk is usefully employed in improving clay soils.

We shall next week inquire into the practical details of the process.—*E. W.*

DURING the past week we have been busily engaged in HARVESTING OUR CARROT AND MANGOLD-WURZEL CROPS. The plan we have adopted is that which was shortly described in a late Number of this Paper. It fulfils the three conditions of success in the preservation of root crops through the winter—it furnishes security from the frost and the wet, and at the same time provides for a sufficient ventilation of the heaps.

The harvesting of root-crops is best done by piece-work. The harvesting of a good crop of Carrots has hitherto cost us from 17*s.* to 25*s.* per acre—that of Swedes and Mangold-Wurzel, from 6*s.* to 10*s.* For this sum the contractor pulls the roots, cuts off the leaves, fills the roots into carts, and gathers and loads the leaves also.

In the operation of harvesting Carrots the spade is required—it is pressed into the ground, and used as a lever by the right hand, while, by the left, the root is pulled up. Each man lifts two rows as he proceeds, and four men forming a company, eight rows are thus pulled and laid regularly on the ground in two lines. Two women can top the roots—*i. e.* cut the leaves off them—as fast as this number of men can pull them; and, leaving the roots in a central row, they throw the leaves into two lateral ones as they proceed. The carts, the number of which, varying according to the distance from the heaps, must be such as will convey the roots off the land as fast as they are ready, follow close upon the cutters; a man and a boy will be able, under ordinary circumstances, to fill both roots and leaves into them as fast as the already-mentioned gang prepare them; and another man and boy will be employed with the roots in the heaps, and the leaves on the land, to pull the roots from the heaps, and the leaves from the carts, as they proceed. We touch upon these details, because it is all-important to the success and economy of the operation that the forces employed in the different parts of it should be rightly proportioned to each other.

The leaves, as we previously observed, will now be the only food for sheep. Whether they may either be hurdled on the ground and pulled to them, or on land already rich enough for a green crop, they may be carried every day to the fold-yard and trod down by the cattle. When, as in the present late season, they are still green, they may be used as fodder. As long as leaves are green they remain useful to the growth of the plant. The only reason why we are now harvesting our Carrot crop, before the roots have stopped growing, is their extreme sensitiveness to frost. This is so great, that it is of the greatest importance to secure them before night all the roots pulled during the day—if they get frozen, though it be ever so slightly, it will be almost impossible to preserve them through the winter.

[illegible] one more remark to make, and that is on the advantage of [illegible] when it is owing to [illegible] always commences at any cut or [illegible] It thus becomes of importance that the surface of the roots should be [illegible] The root fibres should not be cut off, and the leaves should be cut [illegible] from the crown of the root, as that they may fall separately from one another. So far as our experience has hitherto gone, of these points be carefully attended to, and if such a mode of harvesting be adopted as fulfils the three requisites of success before alluded to, there is but little risk of the farmer losing much of his crop by keeping it until satisfaction before the spring.

THE ANOMALIES OF AGRICULTURE.

CHAPTER II.

Could [illegible] of [illegible] retaining [illegible] all powers of perception and reflection, be extended very considerably beyond its ordinary span, so that he might have an opportunity of beholding the phases and revolutions of nations at intervals apart from those periods of interest and connection with the world around us, which make its [illegible] growth and progress too co-ordinate with our own, to strike the optic nerve of the mind with their full evidence, it may yet be conceived, judging only from the history of the last century, that one of the most striking observations would be this strange paradox—that most of the [illegible] and [illegible] improvements in the various arts of life are suggested, proposed, protected, *from without*; resisted, depressed, obstructed, *from within*. It is [illegible] contradictory to the human mind; but it is not the less true for that. Whether it be that in such professions there can never be sufficient interest [illegible] that will resist even the most demonstration, [illegible] is [illegible] bound up with the perpetuation of existing practices, or warped from the true obedience of such facts, the mind shrinks from the contemplation of a change, and retires the proposition of it more readily from both of these, and perhaps other motives combined, yet certain it is that the inventors and improvers in each art have in almost every instance, [illegible] the most virulent opposition to their theories, at the hands of its existing professors. An almost ludicrous instance of this occurred only a few years ago, when the [illegible] railway was first it was proposed in defiance of the thunder of the army of coach proprietors and [illegible] stock-holders, to carry on the [illegible] divine, and pedestrian [illegible] roads instead of stage coaches and [illegible] with singular simplicity, [illegible] the alarmed proprietors [illegible] by the assurance that [illegible] and that the same outcry had been heard and [illegible] upon before in that [illegible] when their speed eclipsed the previous rate of locomotion. Upon the same principle the ingenious Lord Stanhope [illegible] the smiles and jeers of his cotemporaries in general—but the then naval officers and [illegible] of the Admiralty in particular—by the insane proposition that a steam-boiler and apparatus might be stowed on board a ship to propel it by means of paddles, even against wind and tide! And the remarkable feature in the case of the [illegible] in the modern "army of martyrs" was, that in the general derision, the most solemn and deliberate [illegible] with [illegible] him was that of those "experienced naval officers"—men of advanced practice and professional education—men who, in delivering their opinion, [illegible] with a deprecation that [illegible] to habit and usage should be thought to weigh or influence *their* decision—but that really his [illegible] idea and proposition was one of that class that they were bound, after the most patient professional investigation, to pronounce impracticable and preposterous! But Science, like all Truth, is Eternal; and eventually, in that slow but certain defeat which Prejudice, with "sentence of death written upon its brow," * suffers at the hand of Time, is forced—by a sort of popular clamour siding at last with reformations obvious to all but the self-interested; yes, forced upon the profession whose real interest it is, and whose subject-matter it mainly concerns. Yet not in one generation is the Victory often accomplished; for Prejudice will sooner die than yield; and it does die: and thus the [illegible] who hurled on the queer exclamation, "Thank God, old men must die," was not far off the enunciation of a great truth, namely, that it is by the mortality rather than the [illegible] or conviction of generations, that [illegible] and revolutions in practice are accomplished.

It is difficult to resist this train of reflection, when one reads, and often hears, the contemptuous language of some of those who call themselves Farmers of the "good old fashioned school," in reference to those whom they are pleased to class as "march-of-intellect gentlemen," "advocates of Guano and Gypsum, fixers of Ammonia, constructors of Liquid-Manure Tanks, who want to turn a jolly *Farmer* into a "Chemist and Druggist!" This latter imputation, in particular, which wound up a

* T. Carlyle's Hist. of the French Revolution.

perfect *tour-de-force* of after-dinner oratory at a recent farmers' meeting, is worth preserving as a relic, indicating the sort of idea entertained by speakers and thinkers of that calibre, of the use of Chemistry to Agriculture. That they have been applying, and do apply its powers and results, in some of their most miraculous and complicated forms, almost every day of their lives, upon their fields and upon their stock, would probably be as startling a piece of information to them as the announcement that he had been "talking prose" all his life was to the Squire of Barton, or the news of the Marlow Victory to the Warwickshire man who, when the bells rang the merry tidings that peace was proclaimed, asked "What! have we been a-warring then?"

Nothing indeed, to speak but too generally, can be conceived more absurd than the ordinary estimation in which, respectively with its actual rank and importance, Chemistry has been held among the sciences. To this hour a vast and respectable portion of the community are only aware of its existence, so to speak, as a sort of Apothecary's lore—the "Doctor's Assistant"—a kind of subservient pestle-and-mortar affair, over which the magi of the sick-room and hospital wield a cabalistic power, by the aid of certain hieroglyphic signs and symbols scratched with the stump of an execrable pen upon a magic quarter-sheet of paper; a thing of bottles and pill-boxes, hiding their conscious hideousness behind pharisaic rows of enormous glass globes of many-coloured liquids glistening in the blaze of shop gas-lamps! There is a story told of a tribe of American Indians in days long past, who had treated with incredulity and contempt the representations of some English wanderers who had settled amongst them, of the national importance and naval skill of their countrymen. All assurance and explanation were vain, until by chance a British seventy-four happened to anchor off the coast. The natives came from far and near to see it, and some of the chiefs were permitted to go on deck: the stupendous mass of masts and riggings, deck upon deck bristling with guns, mountains of cordage, hundreds of men—through all that there is to see of that

"Sight to dream of, not to tell!"

they were led, speechless with awe. They returned in silence, overwhelmed and downcast, to their homes, and never were heard again to speak upon the subject.

Now, if by some miraculous process of intuition, the great body of those who call themselves Farmers could be gifted with an instantaneous and complete perception of the whole powers of Nature comprehended under that word Chemistry—the natural history of all created substances—of everything cognisable by the physical senses of man, and the laws which govern their infinite unions and variety, co-extensive with matter, *perhaps with space itself*—could they be shown at one comprehensive glance, what it has done for the other arts of life, and its too long neglected importance and specific applicability to theirs—good Heavens! what would they think of their former—their now-existing pretensions and aptitude, as Professors of the art of Cultivation! Would they wonder much at the startling paradox which has lately been quoted from mouth to mouth—That of all members of the community the Farmers, taken as a class, are the least acquainted with the true meaning of the word *Agriculture*? And why? Because, of all pursuits, Agriculture is the one which calls into use the most extensive acquaintance with Nature, and consequently the widest range of physical Science: and of all members of the community, Farmers have hitherto had, generally speaking, the least advantage of an education comprising such studies and therefore adapted to the true exigencies of their future occupation. It is said that a person applying to the late Lord Leicester for a vacant Farm, and in answer to a question put to him, that he had "followed the Plough ever since he was a boy, so he ought to know something about farming."

"Aboo *ploughing* you mean," replied the veteran Agriculturist; "the best Farmer I ever knew was a retired Tallow Chandler." The philosophy of this answer seems borne out by Middleton in his "View of the Agriculture of Middlesex," where he says, alluding to the renegades from other professions to that of the Farmer: "This class forms the most intelligent and accurate of husbandmen. Like converts in religion, they have more zeal, give more application, in short, have fewer prejudices to surmount, and more enthusiasm for their new profession, than those who have been brought up in it from their infancy. They are at the first outset liable to error and mistake from want of practice, but their indefatigable attention makes more than amends for their ignorance of minutiæ; and as they have been at some pains to acquire a knowledge in the Theory of Agriculture, and hence established their ideas on rational principles, they most commonly in the end make a distinguished appearance, as their labours, if unassisted by experience, though often in a new and experimental channel, seldom fail of being crowned with success." As a remarkable instance of the truth of this position, it is not a little gratifying to remember of a few of our readers, the case of a London gentleman whose early life had been devoted to a very general flirtation with the sciences (not excluding Farming), an inquiry being made, about a year and a half, of a neighbouring land-steward (himself a well known judge of stock), how this gentleman got on with his farm, the answer was—"Oh! dear—all the Farmers round laugh at him: he *goes into a field, and digging up a bit of the under soil, pours something upon it, out of a phial he carries in his pocket*—if it pleases he says to his Bailiff, 'You need not put any lime to it this turn' and if it doesn't, he gives some other order about it." Four years had passed away before another opportunity occurred to the same party of asking after him. "By the way, how does Mr. —— get on with his farm?" "Why, bless you, Sir, what the shrew," the best Farmer in the whole county! the crops beat anything that ever was seed of heard of upon that land before. Now here was a man, the better half of whose life had been spent in mere theoretical study and amusement, a good scholar, to be sure, and an excellent gentleman, that turned his mind as actively to Agriculture as it was possible to conceive, and what was perhaps better than all, of a singularly observing temperament, and takes the plough in hand between the age of 30 and 40, and in four or five years is the best farmer in the county. Can anything speak more strongly than this—not that a man is necessarily the better farmer for beginning late in life, as the want of education is at least as essential for attaining anything like perfection in Agriculture, as in any other of the laboriously pre-studied pursuits of human industry?—and that the mind must be early directed to the investigation of the great truths of Nature, and to a course of experimental acquaintance with them when practically applied, "equally at home," in fact, "in the closet and the field" (as they say of another sort of generalship), if ever it would attain to that rapid and almost innate-seeming perception of effects, and adaptation of causes, without which, every operation of mind upon matter must be mere empirical drudgery and chance-work.—*C. W. H.*

(To be continued.)

THE PLOUGH.

THERE are, I conceive, but two questions of any moment connected with the construction of the plough. One of them is, What form of the plough will insure the attainment of those effects which are or should be the object of ploughing? and the other is, What form of the plough will insure the accomplishment of these effects with least exertion of force? These questions about the plough refer, one of them, to the nature and the other to the expense of its operation.

There is no difficulty in determining which of these comes first to be considered. We must, in considering a machine, evidently first ascertain whether it answers the purpose for which it was intended, and then as a subordinate consideration, inquire into the expense of its working; and this view of the subject has, I think, been too much neglected with regard to the plough. True economy most certainly advises the farmer to have his work well done though it be attended by additional expense.

Before attempting to answer the question which thus comes first for our consideration, we must ascertain what those effects are which it should be the object of ploughing to accomplish. The farmer ploughs his land before winter, in order that the frost may exert its influence to advantage in mellowing the soil, and in leaving it when spring arrives in a loose and friable state. He ploughs it also repeatedly before seed-time, either in sprng or autumn, in order to loosen and pulverise it, and thus form a good seed-bed. He also ploughs it repeatedly during a lengthened fallow—his object being in all these cases the same, viz. to expose a fresh surface, and leave the land loose in order to be acted on by the weather. Land is also sometimes ploughed to assist the extirpation of weeds, either by burying them or by loosening the soil, and so letting them be more easily dragged to the surface; and it is also sometimes ploughed in order to cover manure or other matters spread upon its surface.

I need not state here the condition in which land ought to be left by the plough, either when it is intended for a seed-bed, or that it may be most rapidly prepared for one. Both the farmer and the philosopher agree on this point; the latter having the advantage only of knowing *why* such a condition is a good one.

Whether the question be looked at by the eye of the practical, or that of the scientific man, the answer given by each is the same in fact, however different the phraseology may be in which it is expressed. The one says that land should be in sound heart and healthy condition, and the other means the very same when he says that it should be in such a state that free access be given to air and moisture, by which the manure in the soil may be rapidly decomposed, or the germination of the seed rapidly effected.—*M. S.*

ON MINERAL AND INORGANIC MANURES.
No. XXVIII.

BY PROFESSOR CHARLES SPRENGEL.

If peat-ashes contain very little gypsum, common salt, phosphate of lime, and, generally speaking, little of those substances which are amongst the chief nutriments of plants, they have (as a matter of course) little value as manures, which is still less the case the more phosphate of iron they contain. I have analysed several sorts of peat-ashes, which were almost useless, and will state a few of the results, for the sake of proving my assertion.

1. *Peat-ashes from Lüneburg* (reddish). 100,000 parts consisted of—

43,300	parts of	silica.
9,700	,,	alumina.
19,300	,,	oxide of iron, and manganese of iron, partly combined with phosphoric acid.
3,500	,,	oxide of manganese.
2,100	,,	lime.
1,400	,,	magnesia.
0,100	,,	phosphate of lime.
0,100	,,	common salt.
0,300	,,	gypsum.
17,000	,,	carbonic acid, combined with lime and magnesia.
100,000	parts.	

If even 3000 lbs. of these ashes are brought on one acre, the soil will only receive 3 lbs. of gypsum, 3 lbs. of common salt, and 4½ lbs. phosphate of lime, so that only the lime and magnesia (350 lbs.) may expect to produce some effect. The great amount of phosphate of iron (580 lbs.) will, on the contrary, prove hurtful to the plants.

2. *Peat-ashes from Brunswick* (blood-red). 100,000 parts consist of—

48,300	parts of	silica.
4,160	,,	alumina.
29,090	,,	oxide of iron, partly combined with phosphoric acid.
0,480	,,	oxide of manganese.
16,100	,,	gypsum.
1,810	,,	sulphate of magnesia.
0,060	,,	common salt.
100,000	parts.	

Although these ashes contain much gypsum, and might thus be expected to be useful, this is by no means the case, because what is effected in one way by the gypsum, is applied on the other hand by the phosphate of iron, and perhaps also the sulphate of magnesia. Large quantities can never be used, and if 500 lbs. were to be put on the Magdeburg acre, the soil would receive thereby as much gypsum as is ever used of this substance by itself.

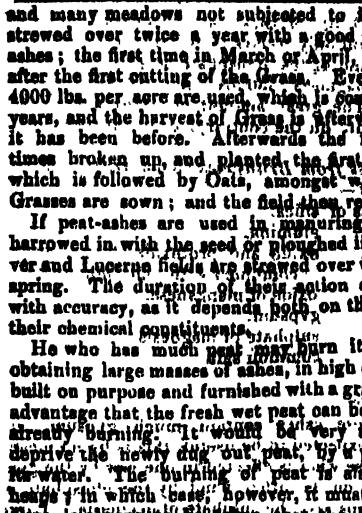
Very often peat-ashes are mixed with burnt lime previous to being used, the effects of which have always been beneficial. With 1000 lbs. of ashes, an equal amount of lime is mixed, and conveyed on one acre of land. There is no doubt that the lime decomposes (in lying in a wet state with the ashes in a heap) the phosphate of iron, and thereby essentially improves the ashes. It might therefore be possible that even the worst ashes, viz., such as possess much phosphate of iron, could be improved by being mixed with lime; which deserves to be experimented upon. Even if it were to contain much sulphate of iron, it would be improved by the adding of lime, as this substance, although it is a good manure, still easily injures the plants.

In Belgium, peat-ashes, previous to being used, are often mixed with guano, whereby the latter are always improved. There it is also asserted that peat-ashes will improve by lying some time in the air, protected from rain. Such ashes most probably contain much sulphuret of calcium, which, as it is more easily soluble in water than gypsum, might supply the plants with too much sulphur; but exposed to air, it changes gradually into gypsum, which is less soluble. In small quantities, however, this substance is not hurtful; on the contrary, it is then a useful vegetable food.

In some places (for instance, the county of Diepholz, in Hanover), sandy loams are improved by peat ashes in the following way:—The coal of peat, but especially the black soil, which lies above the peat of the high moors, and which has been generated by the decomposition of the peats there growing, is strewed 1½ inch thick over the fields, and then worked in dry weather with harrows, till it is dry, when it is burnt with straw, proceeding against the wind. The fire will soon extend over the whole surface, and the peat be converted into ashes; these are now ploughed under shallow as soon as possible, the field is harrowed and sown (after being once more ploughed somewhat deeper) with Rye, which will grow exceedingly well after this operation. This is easily to be explained, by considering that the ashes will not only manure the soil, but the heat also kills all seeds of weeds, and the insects and worms; acting, moreover, beneficially upon the humus, and the protoxide of iron of the soil decomposing the former, and disposing the latter to be converted into an oxide. If, on the other hand, the peat-ashes contain protoxide of iron, ammonia will be generated by the decomposition of water, and the result will be still greater. It has been just stated, that for this operation the black soil lying above the mossy peats of the high moor is used, as we have seen that it will greatly improve the growth of crops. This again proves what important parts certain mineral substances perform in the nourishing of plants, as the chemical analysis of the black soil has shown to me, that it is rich in phosphate of lime, gypsum, common salt, magnesia, carbonate of lime, and potash, whilst the ashes of the Moss-peat lying under the former, contains but very little of these substances, and no potash at all. It is also to be observed that the substances of peat must be entirely converted into ashes; because if they are ploughed under in a state of imperfect combustion the field will be impaired. For the sake of making sure that the whole has been converted into ashes, the burning must not be resorted to until a dry day, which will be best done in the hot season (July, August). It is also good, for the sake of the surer communication of the fire, to mix the earth with a little Moss-peat, as the latter is very inflammable. The best result of this operation will be found on calcareous soils, in fact it is followed by results so extraordinary, that it ought to be resorted to wherever practicable.

The most general use of manuring with peat-ashes is made in the cultivation of high moors; nay, it is here indispensable to burn a great part of the peaty substance, in order that the soil may be planted, as by the burning not only the superfluous amount of humus is destroyed, which (as we have seen before), injures vegetation by depriving it of the necessary oxygen, but the plants are supplied with the required mineral substances. At present not only arable fields but also meadows are manured most advantageously with peat ashes. It is in Holland where they are most employed for that purpose,

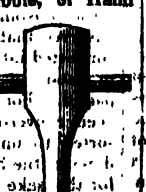
and many meadows not subjected to inundations, are strewed over twice a year with a good quantity of peat ashes; the first time in March or April, the second time after the first cutting of the Grass. Every time 3000 or 4000 lbs. per acre are used, which is continued for three years, and the harvest of Grass is afterwards twice as great as it has been before. Afterwards the meadows are at times broken up, and planted the first year with Flax, which is followed by Oats, amongst which Clovers and Grasses are sown; and the field then rests as a pasture.



If peat-ashes are used in manuring fields, they are harrowed in with the seed or ploughed in shallow. Clover and Lucerne fields are strewed over with them in the spring. The duration of their action cannot be stated with accuracy, as it depends both on their quantity and their chemical constituents.

He who has much peat may burn it, for the sake of obtaining large masses of ashes, in high cylindrical ovens built on purpose and furnished with a grate. This has the advantage that the fresh wet peat can be thrown on that already burning. It would be very advantageous to deprive the newly dug out peat, by a press, of most of its water. The burning of peat is also done in large heaps; in which case, however, it must be already dry. Care is always to be taken that the heat be not too great, else the ashes will lose much of their value; silicates will be formed, which (as we know already) are of no use to the plants. It is obvious that only such peat is to be burnt as experience or chemical analysis has proved to yield a useful sort of ashes.

ON DIBBLING WHEAT.



I have read with much pleasure the remarks of your correspondents, "T. B. Pearson," "A Constant Reader," and the Report from Stow-in-the-Wold, of the superiority of *dibbling* over *drilling* Wheat.

In the autumn of 1836 I dibbled 3½ lbs. of chevalier ten-rowed white Wheat, one corn in each hole only, in rows 6 inches by 12, which covered 64 perches of land; the produce was 16 bushels. I lost a great many ears, in consequence of the field being bordered by the public road: persons passing took the liberty of gathering them, out of curiosity, such sort of Wheat not having been cultivated in the neighbourhood; but still every ounce of seed produced 1*l*. lbs. 3 oz.* This was made public through the pages of the *Reading Mercury*, and recently by Mr. J. Brown, in his Address to Wheat-growers and Agricultural Societies. In February, 1842, I sent the inclosed letter to the editor of the *Mark Lane Express*, the republication of which might be productive of good. I have had much better crops since I have dibbled 4 inches by 9. As your "Constant Reader" calls upon some of your mechanical readers to invent a dibble, I send you an outline of one which I have used for the last six years: it is a very simple instrument, and the dibbles being of cast iron screwed into the cross-piece, after a little use they clean themselves well, unless the land is wet and adhesive. I think it would be complicated, if the dibbles were made to turn half round.

Handle, 1 foot long; stem, 2 feet 6 inches, mortised through the cross-piece, as well as the handle; cross piece, 20 in. long, 3 in. wide, and 1¼ in thick; dibbles, 1¼ in. diam. at the shoulder of the screw, and 3¾ in long from the shoulder. The hole made is hardly ever more than 2 in. deep, on account of the soil tumbling in when the dibble is removed.

However, I beg to call the attention of your "Constant Reader" to the advertisement in your columns, of "Smith's Field and Garden Seed Dibble, or Hand Machine," made by and to be had of Messrs. Cottam and Hallen, No. 2, Winsley-street, Oxford-street. I have not yet seen the machine, but have read a book describing it. I have such an opinion of its usefulness and simplicity of arrangement, that I have no doubt but it will be in general use when known. It is a tube of copper or tin, somewhat of this shape; the hole for the seed is made by pressing down the cross handle, and the seed is deposited at the same time; the quantity of number the operator wishes; it can be adapted to Turnip and Mangold Wurzel seeds, Wheat, Barley, Peas, and also all kinds of garden seeds. It is now in great request.—*W. Bartlett, Surgeon, Marlborough.*

The following is Mr. Bartlett's letter, alluded to above:—"Having seen in a number of the 'Farmers' Magazine' for June, 1841, some remarks on the subject of dibbling Wheat, by Mr. W. Lucas, wherein it is stated that the greater the number of Corns dropped into each hole, the less was the produce; that one grain invariably produced more than two, two more than three, three more than four, up to eight, which number seldom produced more than one stalk or ear, and that of an inferior quality; and having had some experience in dibbling one Corn in a hole, I can vouch for the truth of this statement; the average from one grain is from 12 to 18 ears. I have specimens by me of 81 stalks of Barley, and 42 of Wheat, each from one grain—each stalk producing a perfect ear. As I occupy but a small quantity of land, I am anxious to make the most of it; and the system I have hitherto pursued is spade husbandry and artificial manures. In 1840 I dibbled 108 poles of land with 7 gallons of Beans, making the holes 4 inches apart and the rows 18 inches asunder, dropping one Bean in each hole; immediately the Beans were planted and covered in, the land was manured with one sack of good salt; the produce when threshed was ten sacks, one and half a bushel of Berkshire Ticks, of a superior quality, not having any refuse whatever; each Bean produced three stalks nearly 7 feet high; whilst growing they were declared to be the finest sample ever seen in the neighbourhood.

"After a good crop of Potatoes in 1840, which were manured with gypsum when the stalks were about 6 inches high—a manure not beneficial to cereal crops, consequently not likely to influence the quantity produced by the process adopted for the next crop—early in March 1841, 2 roods, 21 poles of this Potato land were dibbled with 14½ lbs. of Barley, (to which my neighbours have given the name of 'Bartlett's American' from its superior quality) at 4 inches by 9, and deposited at least 3 inches deep and covered in with the feet after the manner adopted with Beans, and the land sown with ashes (made by burning the weeds dug out in cleaning the land, and others growing round the borders of my little field, with fresh lime from the kiln; by placing the weeds and lime in alternate layers and suffering them to remain till combustion was complete) in the proportion of 200 bushels to the acre. The crop was particularly fine, more than 4 feet high, and the number of corns in the ear varying from 27 to 37—some had 39; the whole produce was 31 bushels besides 1½ bushel of Tail-corn; the weight per sack 212 lbs., giving an increase of 117 lbs. for every pound dibbled without the tailing. I employ men to make the holes with the dibble, which makes five holes at once, and children to drop the corn; they work by a line and change their places every time, filling up the holes with their feet as they pass each other; the expense varies from 9 to 10 shillings per acre, according to the fitness of the land for the work.

"Besides the great saving of seed, the greater produce per acre, and its superior quality, considerable advantage would arise to the public at large, by giving employment to a greater number of persons, (who are, through want of work, in absolute want of food,) if dibbling was more generally adopted, as well as spade husbandry. —*W. B., Feb. 7, 1842.*"

* With one error, *quarter* for *quart*.

SKETCHES OF EAST LOTHIAN HUSBANDRY.

Beans.—Since the extension of thorough draining, and the consequent melioration of the soil, and its better adaptation to Turnip-culture, the extent of land devoted to this crop has been annually decreasing. Beans are, however, regarded as peculiarly well suited for the preparation of clay lands for Wheat; and it is owing chiefly to this circumstance that they are cultivated to so considerable an extent in East Lothian.

Beans are always sown after Oats or Wheat. The land intended for this crop is ploughed with a deep furrow in autumn, or early in winter, in order that any new soil which may be brought to the surface may receive the full benefit of the winter's frost. The manure to be applied to the crop is, in many instances, spread upon the stubble, and ploughed in with the winter-furrow; and this practice is much approved of where the land is sufficiently dry to admit of it, as it greatly expedites the work when the period of sowing arrives. The mode of preparing the soil for Beans varies very much in different localities, and under different circumstances, the preparatory tillage being regulated, in a great measure, by the nature and condition of the land and the state of the weather. In the case of dry and light soils, it is usual to give one or more ploughings, and a sufficient number of harrowings, to pulverise the soil, and disengage all root-weeds, which are carefully gathered off before forming the drills; but at the early period of the spring, in which Beans are sown, these operations are but seldom perfectly executed, even upon dry friable soils; whilst upon those of a strong, tenacious character, such a course of preparatory tillage would, except in very favourable weather, be altogether impracticable. On the latter class of soils, therefore, the general practice is to form the drills on the winter furrow, without any previous tillage; but whatever preparation the land may undergo, the drills in which the seeds are deposited are formed precisely in the same manner by the common plough. They are commonly 27 inches apart.

When the dung has not been ploughed in with the first furrow, it is spread on in the field during the winter, and turned over to accelerate the fermentative process a short time before being required for use. The manner of applying it is as follows:—A sufficient number of drills being formed the dung is carried from the heap in single-horse carts, the horse walking in the interval of every third drill, and it is dragged out into small heaps, proportionate to the quantity to be applied per acre. Three or four women follow each cart to distribute the dung equally along the intervals of the drills, and the seeds are then sown by a machine which sows three drills together. According to the method pursued here of drilling with the common plough, a drill is formed by a single furrow, and the dung and seed are covered in by the plough in returning, so that the opening or formation of the drills, the carting and spreading of the dung, the sowing of the seed, and the final covering of the dung and seed by reversing the first-made drills, are carried on in close succession and with much regularity.

The after-culture bestowed upon the crop after sowing is a single harrowing, but before the young plants reach the surface, for the purpose of destroying the annual and other weeds that may be springing up. The subsequent culture given during the growth of the plants consists in horse-hoeing, hand-hoeing, and hand-weeding; the implements employed at horse-hoes are a common plough of small dimensions, drawn by one horse, and a drill-harrow or grubber, with coulters for cutting and tearing up weeds and pulverising the soil in the intervals between the rows. The small plough is used for paring away a portion of the earth from each side of the drills as close to the plants as the plough can go without injuring them, and the drill-harrow both follows to pulverise and level the soil turned up by the plough, and to cut and drag up all kinds of weeds to the furrows. The hand-hoers, women and boys, are then set to work, each taking a drill and cuts up any weeds which may have escaped or had been out of the reach of the previous instruments: weeds growing up among the plants in the rows are pulled by the hand. The horse-hoeing and hand-hoeing are repeated until the weeds are completely cleared off or destroyed, or until the crop has arrived at such a stage that further tillage would be injurious rather than beneficial. Where the soil is very wet, the plants are generally earthed up in the same manner as is done in the culture of Potatoes, but as the drills by being thus raised up occasion some inconvenience in ploughing the land for Wheat after the Beans are removed, this last operation is usually dispensed with, except the land is very flat and liable to injury from the retention of surface water.

When cutting this crop, which is always done by the sickle, two rows are taken together by each reaper, and the Beans are laid down in handfuls across the drills, in which state they remain a week or thereabouts, in order to allow the stems to dry and wither, when they are tied up in sheaves with short straw ropes, previously manufactured for the purpose, and distributed over the field. The sheaves, on being tied, are made up in stooks, in which they remain till ready for stacking. Bean-stacks are made of a small size, with a funnel or wind-kiln, as it is called, through the centre of each, to which there is a free access of air from without, by means of a low tress placed at the bottom.

The period of sowing Beans is usually from the latter end of February to the middle of March. The quantity of seed depends in some measure upon the quality of the land, and the size of the Bean; four bushels per acre is the general allowance. It is a common practice to mix a small quantity of Peas or Vetches with the Beans before sowing. The best quality of Vetch-seed is obtained by this means.

The produce per acre varies from 25 to 40 bushels per acre, but 30 bushels are reckoned a full average crop. The usual weight of Beans is 62 to 63 lbs. a bushel.

Beans are used to a considerable extent in feeding horses and cattle; for the former they are generally boiled with Barley or mixed with Oats, and for the latter they are always made into a kind of coarse meal. It has been already stated that the bread of the farm-servants here consists of a mixture of Beans and Barley ground together. The straw is much valued as fodder for farm-horses.—*T. Sullivan.*

Home Correspondence.

Seaware.—About mid-winter last, some seaware having come on the shore attached to my farm, I had it carted and spread, in the proportion of about 45 one-horse carts per Scotch acre, on poor sandy land, in Oat stubble, intended for green crop this season, and ploughed in without loss of time. In spring the land was again ploughed, harrowed, and otherwise prepared for a crop of Potatoes. When the drills were drawn, African guano—about 5 cwt. to the Scotch acre—was spread in a part of them, and a very little loose earth drawn over it, after which the Potato-seed was planted and the drills covered up in the usual manner, both where there was no manure but the seaware, and where there were both seaware and guano, as above described. The Potatoes were planted on the same day. Those where the guano had been put were much earlier, and abundant in foliage, than those planted on the seaware by itself; indeed, the drills were covered long before any other Potatoes in the field—for I may observe that there was also a considerable quantity of that root planted on good stable manure there. That which attracted my particular attention was the very marked superiority of the crop where the seaware and guano were applied, over that where seaware only had been used. I now regret that a comparative trial of the weight or bulk of the Potatoes thus planted was not made. The fact is, those planted on seaware and guano being earlier at maturity than where seaware only, or stable manure had been applied, they were dug and used in the house and by the pigs immediately after the early Potatoes were done. The man who lifted them, however, states that he believes there was nearly a half—at all events a third—more Potatoes on the land manured with seaware and guano than on that with seaware alone, and they were a very large crop, and of excellent quality. Covering the seaware by the plough, as soon as it is laid on the land, is

a good way of using that manure—perhaps about the best—as its substance is preserved in the soil, which it helps to meliorate, during the process of decomposition. I have been induced to send you the above simple statement in regard to planting Potatoes on seaware and guano, not because I suppose there is any new discovery involved, but from a wish to draw the attention of those agriculturists who have the benefit of seaware for manure, to a mode by which they may raise excellent crops of Potatoes at a moderate expense. I am well aware that abundant crops of Potatoes are often grown, especially on mossy or soft land, manured with a large quantity of seaware alone; but the quality is rarely good, and the crop is generally late in ripening—in fact, scarcely fit for anything but seed. On good dry land there is no doubt that fair crops of Potatoes are raised with seaware for manure, but even here large quantities of this manure must be used. I propose next season to try Turnips manured in the same manner, viz., with seaware ploughed down in winter, and guano applied at sowing time, and have sanguine hopes that the experiment will be a successful one.—*J. Paterson, Whitehouse, Arran, Oct.* 17.

Allotments.—There appears to be a project on foot to regulate allotments by legislative interference—a scheme pregnant with many evils, and contrary to the principles on which this plan for the relief of the poor man should be based. There are objections to any measure compelling a parish to provide garden plots for labourers:—An extra expense is entailed upon rate-payers, a considerable part of which must necessarily fall upon a numerous class of men, who are hardly able to bear their present burthens; the number of parish officers, already more than sufficient for the management of parochial affairs, would be increased. It may be said, an Act of Parliament to compel parishes to provide land for the cultivation of the labourers and artisans, will improve their condition, and decrease the pauper lists. But a difficulty will naturally arise, as to who are the proper objects to benefit by the proposed law. Now, keeping in mind that the small rate-payers are part tenants in renting the land, and will have to pay their proportion in the event of there being any defaulters, they will expect, and with some justice, a portion of it as gardens for themselves. These applications will lead to constant bickerings and confusion. Again, the vardens to be elected as managers will be placed in no enviable position, and will find obstacles thrown in the way of an equitable adjustment of claims, which will prevent competent men from undertaking such harassing duties as they will have to perform. Let us suppose Parliament to have passed the Allotment Bill, and a half-rural parish is desirous to act upon it. Officers are appointed, and instructed to hire 20 acres of land, and apportion them into equal parts, amongst 60 heads of houses, according to the number of persons capable of working in their respective families. This is all very good, provided you have only the above number; but if there are 300, instead of 60, who assert their right to the indulgence, being themselves charged with a share of the expenses, in the event of a failure in the receipts for rent, what is now to be done? How are you to discriminate between the various parties? You cannot say to the hard-working man, who has never yet troubled the parish, and who has been struggling through all times to preserve his independence, "You can live without an increased income—we must pass you over, to relieve the parish rates and get rid of an idle man." Take your idle man, and what is the result?—no rent, and an additional charge to the industrious individual who was refused the land. The Allotment System can only be applied with success, either by individuals or a society, apart from parish officers or Acts of Parliament. The subdivision of land into small holdings is a dangerous precedent, and can never answer any good purpose. No man who is dependent upon his daily labour should have more ground than himself and his family can look after during their leisure hours—and in few instances more than half an acre. Spade husbandry having been proved to be so much superior to ploughing, how comes it that farmers do not more generally use the surplus strength of their parish in this lucrative manner? Dibbling is done by contract; and why should not digging a field be executed in the same manner as navigating—by gangs? Here is at once a fruitful source of occupation, which would obviate the necessity of parliamentary allotments, and render sufficiently effective the common practice of letting garden plots. Prejudice exists against the spade as a chief agricultural implement, on account of the expense. However, an increased produce and lowering the rates will amply repay the experiment, which I have no doubt practical men will acknowledge; and I hope soon to see it more commonly in vogue. I am fully convinced that a number of individuals may almost always be found, resident in a parish, who will be ready to superintend any plan which may be brought forward as a means of alleviating the distress of their poorer neighbours, without the assistance of legislative enactments. Persons anxious to promote the welfare of working men, should, before they advocate any plan which may increase the rates, attend regularly all parish vestries in their neighbourhood, which would convince them of the impossibility of squeezing more out of the small rate-payers than is at present annually obtained from them.—*Falcon.*

Roots of Wheat.—I gratefully acknowledge the reply of "J. C. C." to my query on this subject. I was not aware that attention had ever been publicly directed to the subject, and having this summer traced the roots of Wheat to a depth of upwards of five feet, I was anxious to know whether agriculturists were aware of the fact. In forming a kitchen garden I had occasion to trench a Wheat-field, and found that the soil was matted with fibres to the depth of about 4 feet 6, but stronger roots extended below that depth and were traced from 5 feet to 5 feet 6. The Wheat was a dwarfish variety. Red: so that the roots were, as "J. C. C." remarks, considerably longer than the stems. In the last few months I have asked many not unscientific farmers how deep Wheat roots? I have not found one who could answer the question, and I suspect if the Council of the Agricultural Society were catechised, few, if any, would know anything about it. Such being the case, might not it would confer a benefit on farmers generally, if you would embody the contents of "J. C. C.'s" information in your Leading Article and make it known that the average depth to which Wheat roots is 5 feet; which would, I suspect, be a stronger argument in favour of draining and subsoil-ploughing, and other novel operations of agriculture, than any other which can be urged; and will, in all probability, astonish, even to incredulity, 19 out of 20 of your readers; not to say 99 out of a 100.—*J. R.*

Salt as Manure.—My neighbours are crying out lustily against the depredations of the slugs amongst their Potato crops, scarcely one being free from severe marks. I have escaped this visitation; I attribute it entirely to having used salt last year. After my ground was cleared of the produce, I had it turned up rough and sowed salt broadcast over it; I also used a considerable quantity on my refuse heap, which accumulates during seven or eight months, and is composed of anything and everything I can collect on the premises, which there is a chance of converting into manure. —*Falcon.*

Chidham Wheat.—In answer to your Correspondent "Kirklington," I beg to inform you that Chidham Wheat is derived from a single stem of Wheat found in a hedge at Chidham in Sussex, on the farm now held by Mr. E. Wyatt, and is called so after the place. In Hants some call it Hedge Wheat.—*R. Gibbs, Guildford.*

On Harnessing Draught Animals.—On seeing the print of a portion of a horse and draught-chains in your columns, I was induced to read the paragraph relating to it, and not approving of the plan of harnessing there recommended, I was glad to see "A. J.'s" objections to it in No. 39. I agree with him to a considerable extent, and yet am willing to give due weight to your argument in favour of the plan to which he objects, even if it would do so, to strengthen it by relating a nearly similar anecdote. A fellow pupil called to me, "Try if you are stronger than I am, and pull out this roller." I attempted and failed. Our tutor looking on said, "I can tell you what will enable either of you to accomplish the task. Let one get on the other's back." We severally did so, and could perform it with ease. I am confident no means of adjusting the rope to our bodies would have enabled either of us to have pulled the roller from whence it was, without some additional weight to have given us firmer footing. Now, in the plan of harnessing recommended, the object being to relieve the shoulder at the expense of the back, there can be no additional weight.(!) My principal objection to your plan appears to have been hitherto overlooked. I think it must be apparent that in this method of harnessing, the greater the tension, the more the back-band is drawn down, the more will the neck-collar be raised against the animal's windpipe, thereby tending to choke him. As a proof of such tendency I may perhaps be allowed another anecdote. Three or four years ago, whilst riding, I met my carter half way up a Devonshire-hill, with a load of coal. I stopped him to give some directions for the morrow, and remarked that the back-chain was too tight—the horse would choke. He replied, "Oh no, sir, I was obliged to load forward to get from the vessel's side." The drag-staff was down, but the shaft-horse, a remarkably staunch yet nervous animal, refusing to yield, within two minutes fell on his side. I consider the usual method adopted in this country of attaching the trace to the collar, cramps and confines the shoulders more than necessary, and that it would do so much less if attached higher up the collar, and thus render the carriage-horse less unfit for riding. It is the tension or draught on the lower part of the shoulder I consider that makes the harness-horse so stilty in his action. This I have in great measure prevented in my carriage-horses, by using the swing instead of the fixed splinter-bar, and believe I shall entirely do so, by using Bencraft's patent hames. This invention is a boon to the coach-horse. I would recommend a somewhat similar contrivance for the use of the cart-horse also.—*B. Child.*

Scotch Farming.—It may be interesting to some English brother farmers who read this *Gazette*, to hear from one who has just crossed the border for the first time, an account of a few variations which meet the eye in Scotland, from the farming practised in our "ain dear land," as most of us consider Scotland the mother of improved agriculture. It was chiefly a bird's-eye view I could take of the country as travelling by coach, with the exception of having a talk with one or two farmers. The first thing which must attract attention on entering Scotland is the intelligent physiognomies of the children. This remark may appear rather inappropriate, but I believe that education is the foundation of all good farming. Another thing which struck me was the curious appearance of perhaps from twenty to forty stacks, and sometimes more than eighty, near the farm steadings, about half the size of our round ones, but most of them not thatched nearly so well as those in England. The part I first went through was East Lothian from Berwick, and then nearly through the heart of Mid-Lothian to Edinburgh, from there across the Firth of Forth to St. Andrews, through the fertile county of Fife; and in that distance I am glad to be able to say I only saw two slovenly fields (which were between Cupar and St. Andrews), out of which the Potatoes had not been taken. The reason of the excessive quantity of weeds in these was, I suppose, because the land had been allowed to get foul with previous crops. I noticed also that they ploughed the farmyard manure into the ground in a very green state, which no doubt, where the land is stiff, has the beneficial tendency of keeping it open. Another novelty was that every plough I saw was made of iron, and in some few fields they were working one-horse ploughs, I suppose to open a seed furrow for Wheat. The land I saw varied nearly as much as in England, although none of it required more than a pair of horses to work the plough, which cannot be said of many parts of England. By inquiry I found the Scotch do nearly all their weeding at the summer fallow, and at that time employ large numbers of women. What surprised me exceedingly was not to see one Corn-drill, but quantities of Wheat being sown broadcast. If I had seen pressing in vogue, or any other mode more adapted for light land, I should not have been surprised at the absence of the drill. I may as well add, that at a large farm where I was, they only had the old kind of Turnip cutter, and not any chaff-cutting machine for the horses. You will agree with me that this looks something like the son going a-head of his mother—comparing the best farming of England with that of Scotland. The Turnip crops are much better here than in most parts of England; and I believe they have an average crop of Potatoes, which they pit in the fields, where you may sometimes see heaps a hundred yards long. I was disappointed in not seeing many of our improved implements introduced into this far-famed country. The land certainly does immense credit to the farmers, taking into consideration the climate they have to contend with.—*Titus Oats.*

Societies.

EAST CUMBERLAND AGRICULTURAL SOCIETY.

At the late Annual Meeting and Show of this Society, Mr. Ellison, one of the Judges of Stock, gave the result of his experience in using bones and guano with respect to the Turnip crop. He had used four tons of guano this year, African and Peruvian, and from the appearances of the Turnip crop the African had answered as well as the Peruvian, although there was a wonderful difference in their price. He also had some Turnips sown with bones, which were likely to yield about 23 per cent. less than those which had been sown with the guano. Now this was singular, after what he had heard a very respectable farmer state, that on his farm the only effect on Grass was to make it a greener colour, and that though it made Corn greener for a while at first, it had no material effect upon the quantity produced. This soil was on a thin limestone bed, but he had tried it upon peat moss, and it acted equally well. With respect to the permanency of its effects, he could not yet ascertain it so well, and it was a known fact that bones were permanent in their effect. Corn from land which had been bone-manured would be stronger than from that produced by farmyard manure. But if they might believe a gentleman who had spoken at a meeting of the Royal Agricultural Society, the effect of guano was permanent, and therefore great benefit might be expected from its introduction. He would now say a few words with respect to Potatoes. He held an agency in Lancashire in 14 townships, and had therefore had ample opportunities of observation, and he might say that Potatoes there were a very failing crop indeed; and in his opinion it could be attributed to nothing but cutting the Potatoes before planting them as seed. It was a common saying with many people whose Potato crops had failed, that they had been carried off by the dry rot. But it was no such thing.(?) He was satisfied that it was an insect which penetrated through the Potato when it was cut, and ate up all its juice, so that it was impossible the stem could flourish. He had examined Potatoes in this way, and on taking them up, after being a fortnight or three weeks in the ground, the inside of the Potato was found like a sponge, and perforated with small holes. He had this year six acres of Potatoes, and they were all planted whole. He had also an acre in which the seed was cut, by way of satisfying his neighbours, and enabling them to judge of the difference of produce between the two modes. The six acres were as good as heart could wish for, while the acre in which the seed was cut was not half a crop. There was a tenant whom three years ago he threatened to turn off his farm if he continued to cut his Potato seed. He had seen him the other day, and he told him that it would have been 90*l.* in his pocket, if he had followed his advice, as he had lost 30*l.* a year by the old practice. A very effectual mode to prevent the worm amongst Potatoes was to wash them. Experiments of this kind had been made, and those Potatoes which had been washed when laid up for seed were found to be entirely exempt from this disease, which arose from the egg of an insect being deposited in the eye of the Potato. By washing the Potatoes in the autumn, the ova were of course washed out, and all danger obviated.

FARMERS' CLUBS.

Monmouth.—At the late Annual Meeting of this Club, Mr. Crawford made the following remarks:—The first consideration in Agriculture is climate; this is more of a grazing than a corn country; our green fields are unequalled, but our corn-growing is surpassed in many countries. An English meadow will fat a large ox, while many other countries have not pasture to feed a rabbit. That shows our prodigious advantage over other countries as a grazing country. Our country

is capable of producing green crops, while in the South of Europe they are unable to grow a Turnip or Mangold Wurzel. South America is not capable of growing a third of the turnips we are able to produce. The subject of draining is in this country most important; in other countries there is a lack of water, while in some there is a superfluity. Arthur Young, when he was in Spain, said he saw at a glance what that land there was nothing—water, everything. The subject of irrigation deserves every attention; for himself, he proposed to make 15 or 16 acres of water meadow, and he would tell them the result of what he had already done. On a piece of 7 acres he had mown an average of 2 tons per acre for his first crop, and 2½ tons for the second, which under ordinary circumstances would not have produced half as much. But there was another kind of irrigation. He had constructed a tank for the reception of the liquid from the dung heap, by the use of which a piece of land not an acre in extent, but worth five acres of common pasture. It had been fed by sheep for a month, after which he cut away 2 tons, and afterwards 2½ tons, being at the rate of more than 4 tons of hay from two crops, and there was another crop on the ground which he (Mr. Hall) now had in sight of the house. Suppose any to be disposed, that would be the case of all acres, and would entirely alter the produce of the whole country.

Otley, Mr. Mayo's.—Ripley.—Tells you a letter of a resolution unanimously agreed to at the last meeting of this Club.—The members present.

The first meeting was the usual setting down for discussion for the evening was the usual setting down for discussion on Devonshire Farms, and the best Mode of keeping the Land in the highest state of fertility. That of a Farm, containing 100 acres of arable land, with an average proportion of pasture, the tillage land may be best cultivated by being divided into inclosures of not less than 10 acres each, and the majority of the meeting were prepared to say not less than 15 acres, but the number 10 was inserted for the sake of unanimity. With regard to the Lease it was agreed that they ought to be prepared down to the most advantageous practice, consistent with the keeping of the Land in the highest state of fertility. Of course all annually shorn. As the above are opinions of practical men, they may be interesting to some of your readers.—*Western Times.*

North Cheshire.—At the last meeting of this Club, the subject of breaking up Grass-land was introduced by Mr. Wilson, who moved and Mr. Greenhalgh seconded the following resolution:—"That the practice of breaking up Grass-land in this district, when judiciously conducted, is worthy of encouragement." Mr. Wilson said he had not only drained a large quantity of land, but had also broken up a considerable portion of Grass-land, and he was happy to say that it had answered his expectations. He had applied the same treatment to different soils, and in every instance the crops were improved in quality; while the pasture which had been ploughed up had the same quantity of grass, and much better quality. He had also applied the manure, consisting of the sweepings of the streets of Manchester, to the land which had been under the operation of the plough, and the seven acres (exactly which time he had fixed it could be sent to) gave 6 tons, and 96 lb. of green Grass per acre. Mr. Mitchell's men only exactly a ton. But from the position in which the land would not exhibit success. He admitted that it was, and he did not think the state of the land would continue in quality. Several members objected to the resolution, as it had been decided at the Club previously that the question should be left open, in preference to that no subject should be discussed. The Chairman then called on Mr. Wm. Bray for the paper on the Economy of Labour. Mr. Bray, in introducing the subject, spoke of the difficulty of understanding any guidance without the view of creating an equitable remuneration in the mind of the labourer, as the only object in the improvement of the dwelling. It had been the belief, and under that impression he had formed it, that would engage good and skilful servants to the advantage of the employer and employed alike. In order to economy, regularity and time should be done with regularity and that each hour would be fixed, and every labourer should be expected to commence his work accordingly, and the master engage the labourer that would allow the least time for meals, and that would their labour regularly and quickly, and be better paid and rewarded than the man with more frequent meals, who by say an hour, would thus waste, and a certain time the winter months. Mr. Bray then read the following defined and regulated, and shall be considered to describe at some length the irregularities now existing in the district, and their injurious effects. After strongly urging the propriety of removing such irregularities on the ground that such a change would lead to a better understanding between master and man, by removing many causes of needless discontent, Mr. Bray proceeded to say that he thought it very desirable that what constitutes a fair day's work in the various branches of agricultural labour should be determined and generally understood. From inquiries, he found that at present there existed not only various but also contradictory opinions on the question, the difference in the statements made to him by different farmers, amounted to 15 to 20, and even to 30 per cent. He thought that there should be some fixed rule, that some of the practical men of the neighbourhood should give the subject a careful consideration, and state in a pamphlet form their opinion as to what was considered a day's work, according to the custom or usage of the neighbourhood. Should the general opinion—supposing the difference of opinion to exist—be generally known, he thought that this would have a much greater quantity of labour being done by piece-work, a mode of labouring every way more desirable for the employer, and tending to put a premium to industry and ingenuity. The objection—especially the idleness and neglect among them—a mode, too, which would effectually tend very much to the advantage of their employers. It might, perhaps, be objected that the great difference found to exist on the same species of work would prevent its general adoption, but he would remark to them that it was the same with manufactures, and yet most of that work was done by the piece. Others might say the men will slight their work; but they had the same resource as they have in manufactories; such men should be discharged, and others taken that will do better.—An interesting discussion followed, concluded by Mr. James moving for a committee to ascertain the quantity of labour of the various kinds usually performed, and to settle the hours of labour, in order that a uniform system might obtain in the district.

Morpeth.—The Annual Meeting of this Society was held at Morpeth, on the 3d instant. The following remarks were made by Mr. Left, of Trusthorpe:—"The landlords have not done all they might do, in promoting the employment and welfare of the industrious classes. There is one thing in which they can materially assist them,—by breaking up of Grass-land. There is a great deal of Grass-land (I should call it waste land) that might be broken up with the greatest advantage. I know very well that it would be utterly profitless to break up the worst descriptions of Grass-land. But the land that I mean should be broken up is not of the worst quality, but of a middle description—land full of water, and generally producing nothing but Rushes. You are all practical men, and I know will bear me out in what I am saying. You must break up Grass-land if you would increase the value of your farms, the amount of your produce, and the demand for labour. Which farm is it that does most good to the community? I suppose, as you will all answer, that which affords the greatest amount of labour, and yields the greatest quantity of food, and I say by this means you will give employment to more labourers, and greatly increase the produce. I know that great improvements have taken place in this part of the county of late years, by breaking up what is called Grass-land. I can recollect, and my life is not a long one, when you might travel from every town of Horncastle to Caistor, and see wold land covered with Gorse and Bracken, and now they produce plentiful crops of Wheat, of seeds, and of Turnips. I know that landlords generally entertained a great prejudice against ploughing up Grass-land, but where they have permitted it, it has been attended with the best result. I occupy a farm at Market Stainton, where I have had liberty to break up upwards of 100 acres. It is now only twelve years since I entered upon it, and I will venture to say that I grow three times more corn, and keep more stock by half; and I am sure I have no hesitation in saying that if the property were brought to the hammer, it would make from 15*l.* to 20*l.* per acre more than in its original state. I know there is a great abundance of land in this county which is now almost profitless, which might be made to produce a great deal of corn, employ a large amount of labour, and be greatly improved in value by this process."—Mr. Brothwell stated that he went to visit a large farm, but looked in vain for a piece of Grass-land. He said, "Where is your Grass-land?" "I have none," said his friend, "and I want none; it's only the old-fashioned folks on the other side of the Witham that want Grass-land." Mr. B. stared at him, and began to think the fellow would only be badly off for pro-vender, for he feared he would have to feed his horse as well as cattle with cut-and-come-again, and his friend, who is a most successful and intelligent farmer, bid no more Grass-land than he had.—Mr. Stanhope said, "I have thought the matter over a good deal, and have talked with several gentlemen on the subject, and I think nobody would plough up good land, and at the same time nobody would keep bad. I do not wish to go in a hurry where I should afterwards be sorry for. It is easy to say plough up Grass-land. There is so much easier to plough up Grass-land than it is to [illegible] in its present condition, [illegible] now consistent [illegible] Only the other day I [illegible] and I was told [illegible] and [illegible] what I should [illegible] It might have been [illegible] something [illegible] and I was told [illegible] that great improvements have taken place in this part of the county of late years, by breaking up what is called Grass-land. I can recollect, and my life is not a long one, when you might travel from every town of Horncastle to Caistor, and see wold land covered with Gorse and Bracken, and now they produce plentiful crops of Wheat, of seeds, and of Turnips. I know that landlords generally entertained a great prejudice against ploughing up Grass-land, but where they have permitted it, it has been attended with the best result. I occupy a farm at Market Stainton, where I have had liberty to break up upwards of 100 acres. It is now only twelve years since I entered upon it, and I will venture to say that I grow three times more corn, and keep more stock by half; and I am sure I have no hesitation in saying that if the property were brought to the hammer, it would make from 15*l.* to 20*l.* per acre more than in its original state. I know there is a great abundance of land in this county which is now almost profitless, which might be made to produce a great deal of corn, employ a large amount of labour, and be greatly improved in value by this process."—Mr. Brothwell stated that he went to visit a large farm, but looked in vain for a piece of Grass-land. He said, "Where is your Grass-land?" "I have none," said his friend, "and I want none; it's only the old-fashioned folks on the other side of the Witham that want Grass-land." Mr. B. stared at him, and began to think the fellow would only be badly off for prov

ground, if you can do it conveniently; this will prevent the south-west wind from breaking into the garden. Having made choice of a plot of the ground containing eleven hills square, place the bin upon the hill which is in the centre, having five hills on each side; and when these hills are picked, remove the bin into another piece of ground of the same extent, and so proceed till the whole Hop-ground is finished. When the poles are drawn up to be picked, take care not to cut the bines too near the hills, especially when the hops are green, because it will make the sap to flow excessively. The Hops must be picked very clean, i. e., free from leaves and stalks; and, as there shall be occasion, two or three times in a day, the bin must be emptied into a Hop-bag made of coarse linen cloth, and carried immediately to the oast or kiln to be dried; for if they should be long in the bin or bag, they will be apt to heat and be discoloured. If the weather be hot, there should be no more poles drawn than can be picked in an hour, and they should be gathered in fair weather, if possible, and when the Hops are dry; this will save some expense in firing, and preserve their colour better when they are dried. The crop being thus bestowed, take care of the poles for another year, which are best to be laid up in a shed, having first stripped off the haulm from them; but if you have not that conveniency, set up three poles in the form of a triangle, or six poles (as you please), wide at bottom; and having set them into the ground, with an iron picker, and bound them together at the top, set the rest of your poles about them; and being thus disposed, none but those on the outside will be subject to the injuries of the weather, for all the inner poles will be kept dry, unless at the top, whereas, if they were on the ground, they would receive more damage in a fortnight than by standing all the rest of the year. The best method of drying Hops is with charcoal, on an oast or kiln, covered with hair-cloth, of the same form and fashion that is used for drying malt. There is no need of particular directions for making these, as every carpenter and bricklayer in those countries where Hops grow, or malt is made, knows how to build them. The kiln ought to be square, and may be of 10, 12, 14, or 16 feet at the top, where the Hops are laid, as the plantation requires and room will allow. There ought to be a due proportion between the height and breadth of the kiln and the begnals of the middle where the fire is kept; viz, if the kiln be 16 feet square on the top, it ought to be 9 feet high from the fire, and the middle ought to be 6½ feet square, and so proportionable in other dimensions. The Hops must be spread even upon the oast, a foot thick or more, if the depth of the curb will allow it; but care must be taken not to overload the oast if the Hops be green or wet. The oast ought to be first warmed with a fire before the Hops are laid on, and then an even steady fire must be kept under them; it must not be too fierce at first, lest it scorch the Hops, nor must it be suffered to sink or slacken, but rather be increased, till the Hops be nearly dried, lest the moisture or sweat which the fire has raised fall back and discolour them. When they have lain about nine hours they must be turned, and in two or three hours more they may be taken off the oast. It may be known when they are well dried by the brittleness of the stalks and the easy falling off of the Hop-leaves. It is found by experience that the turning of Hops, though it be after the most easy and best manner, is not only an injury to them, but also a waste of fuel and time, because they require as much fuel and as long a time to dry a small quantity, by turning them, as a large one. Now this may be prevented by having a cover (to be let down and raised at pleasure) to the upper bed whereon the Hops lie. This cover may be also tinned, by nailing single tin plates over the face of it; so that when the hops begin to dry and are ready to burn, i. e., when the greatest part of their moisture is evaporated, then the cover may be let down within a foot or less of the Hops (like a reverberatory), which will reflect the heat upon them, so that the top will soon be as dry as the lowermost, and every Hop be equally dried. As soon as the Hops are taken off the kiln, lay them in a room for three or four weeks to cool, and toughen; for if they are bagged immediately they will powder, but if they lie a while (and the longer they lie the better, provided they be covered close with blankets to secure them from the air), they may be bagged with more safety, not being liable to be broken to powder in treading; and the harder they are trodden the better they will keep. The common method of bagging is as follows:—Have a hole made in an upper floor, either round or square, large enough to receive a Hop-bag, which consists of four and a half ells of all-wide cloth, and also contains ordinarily two hundred and a half of Hops; then tie a handful of Hops in each lower corner of the bag to serve as handles to it; and then fasten the mouth of the bag so placed that the hoop may rest up on the edges of the hole. Then the that is to tread the Hops down into the bag, treads the Hops on every side, another person continually putting them in as he treads them, till the bag is full; when being well filled and trodden, they unrip the fastening of the bag to the hoops, let it down, and close up the mouth of the bag, tying up a handful of Hops in each corner, as was done in the lower part. Hops being thus packed, if they have been well dried, and laid up in a dry place, will keep good several years; but care must be taken that they be not spoiled by the mice making their nests in them.—*E. P., in the Scientific and Practical Agriculturist.*

Gypsum, a fixer of Ammonia.—Gypsum is frequently also applied in a state of powder, as a top-dressing to land, and is said not only to afford food to such plants as require sulphuric acid and lime, but that it also operates as a means of fixing and retaining the ammonia, with which the rain is impregnated, which would otherwise evaporate before the plant could seize upon it. In our *concern*,* where we have a great number of horses, we use gypsum in our stables, strewing it on the floor, which *arrests* the ammonia as it is formed, and [illegible] not only helps to preserve a very [illegible] also renders the stables much more wholesome for the horses. I have also, as an experiment, [illegible] in the stables a plate containing diluted [illegible] acid, and have observed small crystals of sulphate of ammonia forming on the edges of the plate, from the acid combining with the ammonia floating in the stable gaseous state. In the dung stables that are [illegible] but without lime, which are so charged with ammoniacal vapours, that when you enter your eyes are affected, a little gypsum were strewed on the floor every day, or trays containing sulphuric or muriatic acid were suspended, all that offensive smell would be done away, and the stable be much more healthy for its inhabitants.—*On the Use of Gypsum, &c., by M. Briggs, Wakefield.*

Notices to Correspondents.

AGRICULTURAL REPORT OF NORFOLK.—*S. D. E.*—It is certainly a useful book; and would probably be beneficially employed as you propose.

BONES.—*H. A. S.*—The present is the best time to apply bone-dust to Grass land. Apply 16 to 20 bushels per acre.—We never knew a horse refuse Lucerne.

COWS.—*Chepstow Subscriber.*—In our experience of oil-cake as food *for sheep*, the addition of 1 lb. diminished the consumption of Swedes from 6 to 5 lbs; it is probable that 4 to 6 lbs. given daily to a cow would diminish the quantity of the other food given to it to three-quarters its former amount; at the same time enriching the milk afforded. The amount of cake may be given broken in small pieces by the ordinary cake crusher, to the cows confined in sheds. There does not exist, in the case of the cow or sheep, the same necessity for finely reducing their food, that there is in the case of the horse and of others which do not chew the cud.

FLAX SEED.—*An Old Grazier.*—Several articles on Flax-seed as food, by Mr. Sproule, which have lately appeared in our columns, will give you a good deal of information. The compound is prepared on the farm.

FOOD FOR SHEEP.—*Subscriber.*—Oil-cake broken in small pieces should be given to them in a trough to the amount of from 12 to 16 ozs. a-piece each day. Oil cake and hay will fatten sheep; they will need water.

GUANO.—*Dublin*—This and all other manures, whose value depends partly on soluble ingredients, is best applied in spring—say early in April

HOPS.—*Humulus, Bradford.*—The male plants are useless. In the hope of eliciting an account of the Hop-cultivation of Kent and Sussex we shall insert your letter next week.

MR. WARNES' BOXES.—*Subscriber*—Perhaps next week.

PIGS.—*Subscriber.*—The water in which Swedes, &c., have been boiled is not injurious.

POTATO CULTURE.—*J. L.*—You may as well dig in the manure *now*; you may safely take your second crop of Potatoes.

POULTRY.—*Original Subscriber.*—We never noticed the fact to which you allude, and know not how to explain it.

STALL-FEEDING.—*H. S. T.*—The heat and itching of the skin is an almost constant attendant on high feeding, particularly if Bean meal (in which nitrogenised elements abound) forms a large portion of the diet. It may be moderated very much by giving occasionally the following powder in the food:—Super-tartrate of potash, 1 oz.; Nitrate of potash, 6 drs.; Flowers of sulphur, 4 drs. If the itching is excessive, change and moderate the food.—For destroying the vermin of store cattle employ the following:—Sulphur vivum, 4 oz.; Oil of tar, 4 oz.; Whale oil, 1 pint; to be gradually mixed together. Sometimes the two latter ingredients alone will prove effectual.—*W. C. S.*

WHEAT.—*H. Dowling.*—Wheat often, indeed generally, sends out roots from the first joint in the straw, but seldom in so early a stage of its growth as in your specimen.——*T. Paul.*—Sow guano at the rate of 2 cwt. per acre, and nitrate of soda at the rate of 1 cwt. per acre, mixed together, broadcast; sow on a wet day in April over your young Wheat: see above—Guano. Use the *fine* bone dust, not the half-inch kind.

*** As usual, many communications have been received too late.

Markets.

SMITHFIELD, MONDAY, Oct. 28.—Per stone of 8 lbs.

Best Scots, Herefords, &c.	3s	10	to 4s	0	Best Downs & Half-breds	3s	10 to 4s 0
Best Short Horns	3	6	3	10	Best Long-wools	3	6 3 10
Second quality Beasts	3	0	3	2	Ewes and second quality	3	0 3 6
Calves	3	4	4	2	Pigs	3	4 4 0

Beasts, 4070; Sheep and Lambs, 29,860; Calves, 114; Pigs, 481.

Our supply of Beasts to day is very large, and much of it of inferior quality. It is difficult to make 4s of anything, yet, the best beef not being very plentiful, that price is obtained in several places. Many middling ones are left unsold. There are a few more Sheep, but the best qualities are still readily sold at about 4s per 8 lbs. Veal trade is heavy; the best Calves are, with difficulty, disposed of at about 4s 2d per 8 lbs. Pork-trade is steady.

FRIDAY, Nov. 1.

We have more Beasts to day than are required for the trade; the demand being very limited. A few of the best Beasts made 4s per 8 lbs., but 3s 10d is the more general price. Short Horns about 3s 8d, with some at 3s 10d; second quality 3s 6d to 3s 8d. Sheep trade is very heavy; the demand on Friday, this time of the year, being generally small, we are overdone in quantity. The dead-trade has also been very bad all the week. The best Downs, &c. realise nearly 4s, and Lear wools 3s 10d per 8 lbs. Ewes, &c. 3s to 3s 6d. It is with difficulty the best Calves make 4s per 8 lbs. Pork-trade remains about the same.

Beasts, 627; Sheep, 4630; Calves, 213; Pigs, 200.

41, West Smithfield.

POTATOES.—SOUTHWARK WATERSIDE, Oct. 28

In consequence of the arrivals being large at the time you received our last report, and the supply being also liberal during the past week, these together have been more than equal to the demand, which has caused a great depression in our Markets, and a considerable reduction in the prices. The best samples of York, Scotch, and Devon, moved off at the annexed quotations; but the inferior samples of Reds, and the different samples of Whites, were a complete drug.

York Reds	-	-	45s	to 70s	Kent and Essex Whites	-	- to 65s
Perth	-	-	—	60	— Kidneys	-	- 60 65

				Inferior	-	-	— —

* Flockton Colliery, near Wakefield.

COVENT GARDEN, Nov. 2.—The market has been well supplied during the past week, but the demand has been comparatively trifling; trade in general is dull. Amongst Pine-apples there are some good fruit which are offered at last week's prices. Little variation has taken place in the prices of Grapes; good samples of Black Hamburgh bring about 4s. per lb., and the best foreign Grapes are selling at about 1s. 6d. per lb. The principal dessert Pears are the Marie Louise and Louise Bonne; these, as well as other varieties have not varied in prices since our last Report. Apples are also offered at nearly the same prices as quoted last week. A few specimens of Coe's Fine Late Red and other Plums are still in the market, but they are very scarce. Damsons are almost over. Nuts of all kinds are sufficient for the demand; good Walnuts bring about 5s. per bushel. Quinces are plentiful. The prices of most kinds of vegetables remain nearly the same as last week. Brocoli is not quite so plentiful. Cauliflowers are good and sufficient for the demand; as are also Cabbages, Savoys, Brussels Sprouts, and other winter greens. We noticed some fine samples of French Beans, which are selling at nearly the same prices as last week. Abundance of Turnips and Carrots are offered; and celery of good quality continues to be well supplied. A few Tomatoes may still be obtained; they are a little cheaper. Endive, Lettuces, and other salading are offered at nearly the same prices as last week. Among Cut Flowers we noticed Bignonia venusta, Combretum purpureum, Allamanda cathartica, Mandevillia speciosa, Thibaudia, Chinese Primrose, Leschenaultia formosa, Polyphyllum tenuifolium, Gloxinias, Heaths, Amaryllises, Hollotrope, Neapolitan Violets, Camellias, Pelargoniums, Verbenas, Camellias, Picotees, and Roses.

FRUITS.

Pine Apple, per lb., 8s to 9s 6d					Filberts, per 100 lbs., 75s to 80s		
Grapes, Hothouse, p. lb., 1s 6d to 3s					Chestnuts, per peck, 1s to 2s		
— Spanish, per lb., 1s to 1s 6d					Walnuts, per bushel, 3s to 5s		
— Portugal, per lb., 1s to 2s					— — shelled, 12s to 24s		
Melons, each, 1s to 3s					Cocoa-nuts, per hf.-sv., 2s		
Plums, per half sieve, 2s 6d to 3s					Lemons, per dozen, 1s to 2s		
— Imperatrice, per pannet, 2s 6d					— per 100, 6s to 16s

Carrots, per doz. bch., 2s to 3s					Mushrooms, per pottle, 10d to 1s 6d		
Basil, per bunch, 2d to 3d					Small Salads, per punnet, 6d to 9d		
Horse Radish, per bundle, 2s to 3s					Watercress, per doz. bun., 2d to 3d		
Savory, per bunch, 2d to 3d					Parsley, per sieve, 2s to 3s		
Cucumbers, Frame, each, 3d to 6d					Tomatoes, per pound, 6d to 1s		
— Ridge, doz., 2d to 3d					Grape Leaves, per bundle, 6d to 1s		
Spinach, per sieve, 1s 6d to 2s					Tarragon, Green, per bunch, 1d to 2d		
Scorzonera, per bunch, 1s to 1s 6d					Grape Mint, per bunch, 3d to 6d		
Salsafy, per bunch, 1d to 1s 3d					Marjoram, per bunch, 2d to 3d		
					Chervil, per punnet, 2s to 3s		
					Chilies, per 100, 1s to 2s		

HOPS, FRIDAY, NOV. 1.

Since our last statement the Hop-Market has gradually improved, and today our quotations are as follow:

Choice Mid and East					Choice Old of Kent	7l 15s to 8l 8s	
Kents -	-	10l 10s to 12l 12s			Ditto Yearling	7 7	7l 15s

The Duty is still estimated at 130,000l.

FARNHAM & BARRS, Hop-Factors.

MARK-LANE, MONDAY, Oct. 28.

The supply of Wheat from Essex, Kent, and Suffolk was moderate this morning, and sold readily at the prices of last week; in Foreign there was little doing, and its value remains unaltered. Having a small attendance of the Barley buyers, in consequence of the Queen's visit to the City, this article sold slowly at our late quotations. Beans and Peas of all descriptions are fully as dear. Notwithstanding the large arrival of Oats, they met a tolerably active sale, and we observe no alteration in their value.

BRITISH, PER IMPERIAL QUARTER.						s.	s.
Wheat, Essex, Kent, and Suffolk					White	40 46	Red - 42 46

Foreign	2786	—	7310	1200	14000	—	609	855

FRIDAY, Nov. 1.

The attendance at Market this morning was small, the extent of business limited. In Wheat, either English or Foreign we observe no alteration. The best qualities of English Malting Barley support their late value, but, having a large arrival of Foreign it met a slow sale, and must, with secondary sorts of home growth be quoted in favour. Beans and Peas maintain Monday's prices. New Irish Oats are a very dull sale, but, notwithstanding a good supply of Foreign, they and all descriptions of old are fully as dear.

ARRIVALS THIS WEEK.

KINGSTON AND LAY.

WOOL.—BRITISH, FRIDAY, NOV. 1.

Our Market has been very quiet for some time past, but few sales have been effected. In fact, as usual, lower prices have been submitted to, but we do not think this has been generally the case. Notwithstanding the accounts from the manufacturing districts of the lessening production, an opinion pretty generally obtains that prices will rally. The light stock in the hands of the growers, together with moderate rate of provisions, seems to favour such opinion.

	per lb.			per lb.

JAMES PEMAN, Wool Broker.

STEPHENSON AND CO., 61, Gracechurch-street, London, and 17, New Park-street, Southwark, Inventors and Manufacturers of the Improved CONICAL and DOUBLE CYLINDRICAL BOILERS, respectfully solicit the attention of scientific Horticulturists to their much approved method of applying the Tank system to Pineries, Propagating Houses, &c., by which atmospheric heat as well as bottom heat is secured to any required degree without the aid of pipes or flues. S. & C. have also to state that at the request of numerous friends they are now making their Boilers of Iron as well as Copper, by which the cost is reduced. These Boilers, which are now so well known, scarcely require description, but to those who have not seen them in operation, prospectuses will be forwarded as well as reference of the highest authority; or they may be seen at most of the Nobility's seats and principal Nurseries throughout the kingdom.

S. & Co. beg to inform the Trade that at their Manufactory in New Park-st., every article required for the construction of Horticultural buildings, as well as for heating them, may be obtained upon the most advantageous terms.

Conservatories, &c. of Iron or Wood, erected upon the most ornamental designs. Balconies, Palisading, Field, and Garden Fences, Wire Work, &c. &c.

BURRIDGE AND HEALY'S NEW BOILER and FURNACE for HORTICULTURAL PURPOSES.
Registered under 6 & 7 Vict. Cap. 65.
No. 130, FLEET STREET, LONDON.

BURRIDGE and HEALY respectfully inform the Horticultural Public that they have constantly on hand an extensive assortment of their new Boiler and Furnace Doors. In very numerous cases where they have been fixed, they have the highest testimonials of their complete success: for the further assurance of those who may require this apparatus, BURRIDGE and HEALY refer them to the Horticultural Society's Gardens, Chiswick; also to Mr. GIBSON, Garden Architect, &c. &c., Chiswick Nursery, in the same neighbourhood, where the apparatus may be seen in successful operation, in connection with their new Tanks. The following are the present prices:—

Plain Boiler.	Patent Double and Range.	Fire-box Deep Flue.	Flue Boiler.	Dairy.	Will heat of Pipe.	Forcing Pit, Length by feet.
ft. in.	£ s.	£ s.	£ s.	£ s.	Feet.	
10 1 5	20	7 6	6 6	6 6	30 feet.	12 to 20
Ribbed Boiler.						
10 2 2	20	10 6	7 6	6 6	50 to 70 ft. 4 in.	Under 25 to 40
12 2 15	30	12 6	7 6	6 6	90 to 120 feet.	40 to 60
14 3 10	35	17 6	8 6	6 6	150 to 200 feet.	65 to 100
18 5 5	45	25 0	8 6	6 6	300 to 400 feet.	Warm a grapery 35ft. long, and a pit 50ft.
24 8 15	80	35 0	8 6	7 6	600 to 800 feet.	

If 8-inch pipe be used, one-third more. If 2-inch pipe, as much more.

The above quantities are rough estimates, which may be varied by enlarging or contracting the fire, or by regulating the fire door. It is possible to heat a much larger quantity of pipe with the boiler, but it would be done at great loss of fuel. The above proportions can be gratefully relied on as a near approximation to what is correct.

WIRE-WORK, HOT-WATER APPARATUS, GREEN-HOUSES, &c.

ST. THOMAS BAKER, MANOR-HOUSE, MANOR-PLACE, KING'S-ROAD, CHELSEA, Manufacturer of INVISIBLE WIRE-FENCE, to resist Grazing Stock, and rendered Rabbit-proof. WIRE-WORK for Trainers, Arches for Walks, Bordering, Flower Stands, Pheasantries, &c. HORTICULTURAL BUILDINGS, Green and Hothouses, Conservatories, &c. The same heated by HOT-WATER APPARATUS, on improved and economical principles.

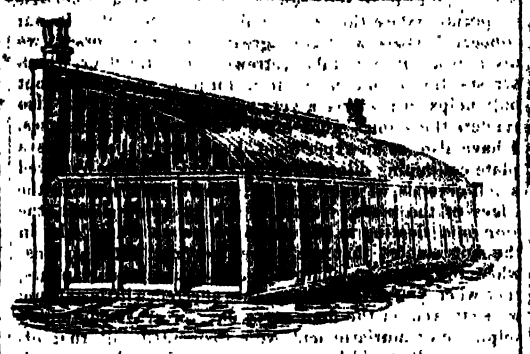
Parties waited on in Town or Country, and Drawings and Estimates free. Work roofed in the country.

Ward's Cases, or Domestic Greenhouses.

HOT-WATER APPARATUS FOR HEATING HORTICULTURAL BUILDINGS, DWELLING-HOUSES, CHURCHES, and MANUFACTORIES, upon improved principles, and at very moderate charges, erected by DANIEL and EDWARD BAILEY, 272, HOLBORN.

D. and E. BAILEY having devoted much time to the consideration of this subject, and had much experience in the erection of apparatus for the above-mentioned purposes, have, by improvements suggested in their practice, rendered their mode of heating not only very efficient, but very simple, and have combined durability in the apparatus with economy in the charge. They have erected apparatus in England, Scotland, and Ireland, for many noblemen and gentlemen, and have had the honour to be employed by the Horticultural Society of London, in executing the works of their splendid Conservatory, lately erected at Chiswick.

D. and E. BAILEY also construct in metal all descriptions of Horticultural Buildings and Sashes, and invite noblemen, gentlemen, and the public to an inspection of their various drawings and models, at 272, Holborn, where they have the opportunity of exhibiting, amongst other metal works, an extremely complete and convenient kitchen apparatus for range, adapted for the continued supply of hot water, and an arrangement of the oldest more complete than has hitherto been brought before the public.



D. and E. BAILEY were the first to introduce metallic curvilinear houses to horticulturists, and can refer to the Conservatory attached to the Pantheon as one of their works, besides many others in this country and on the Continent.

D. and E. BAILEY have prepared a quantity of the Galvanic Plant Protectors, which are now ready for immediate delivery; they beg to introduce to public notice a new Trough Pipe, for Orchidaceous or other Houses where vapour is constantly, or at intervals required, and which may be seen at their Manufactory.

CONICAL BOILERS.—The Boilers invented by JOHN ROGERS, Esq., are made of several sizes, and may be obtained of JOHN SHEWEN, Ironmonger, Sevenoaks, Kent.

They may be seen in operation at Messrs. Chandler's, Vauxhall; Loddiges', Hackney; Henderson's, Pine-apple-place, Edgware-road; Rollisson's, Tooting; Pontey's, Plymouth; The Horticultural Society's Gardens, Chiswick; and in the Gardens of the Royal Botanical Society, Regent's-park.

COTTAM AND HALLEN, ENGINEERS, IRON-FOUNDERS, &c., &c., No. 2, WINSLEY-STREET, OXFORD-STREET, LONDON, and at CORNWALL ROAD, LAMBETH.

HOTHOUSES, CONSERVATORIES, &c., made upon the most improved principle, either of iron or of iron and wood combined, which can be fixed complete in any part of the Kingdom, at very low prices.

HOT-WATER APPARATUS for heating Hothouses, Conservatories, and Greenhouses; Churches, Public or Private, Buildings, &c., with COTTAM'S PATENT or ROGERS'S BOILERS. After 15 years' experience, and having fixed upwards of 2000 Apparatus for the above-mentioned purposes, and by various improvements which they have made during that time, C. and H. can with confidence undertake the erection of similar Apparatus upon the most extensive scale.

Materials may be had for those who wish to fix their own Apparatus.

THE TANK SYSTEM on an improved principle, that will heat the house at the same time, without pipes.

IRON HURDLES, best Wire for Strained Fencing, Ornamental Iron and Wire-work, Garden Chairs, &c., &c., and every description of Implement for AGRICULTURAL and HORTICULTURAL PURPOSES.

Show Rooms at their Manufactory, 2, Winsley-street, Oxford-street, where a large assortment of the above can be seen.

GUANO (GENUINE PERUVIAN & BOLIVIAN) ON SALE, BY THE ONLY LEGAL IMPORTERS, ANTONY GIBBS AND SONS, LONDON; WM. J. MYERS AND CO., LIVERPOOL;
And by their Agents,
COTESWORTH, POWELL, AND PRYOR, LONDON; GIBBS, BRIGHT, & CO., LIVERPOOL and BRISTOL.
47, Lime-street, Nov. 2, 1844.

WHEAT-SOWING.

GUANO; Genuine Peruvian, Bolivian, and Ichaboe, on Sale; also Potter's Guano, Gypsum, Sulphuric Acid, Sulphates of Iron and Copper, and all other manures. Synopsis of prices, and mode of use, on application, &c.—Apply to MARK FOTHERGILL, 40, Upper Thames-street.

MR. LAWES' MANURES.—Mixture for Wheat, 7l. per ton; Super-phosphate of Lime, 7l. per ton. To be had at the Factory, Deptford Creek, near London.

Super-phosphate of Lime, in a concentrated form, may also be procured at Messrs. WARNER'S, 28, Cornhill, in 7 lb. packets, price 1s.

WHEAT SOWING AND GRASS DRESSING.

BRAIN'S GUANO, superior to any imported, being of uniform strength and composition, see Analysis, "Farmers' Journal," Oct. 21, 1844.

TESTIMONIAL.—Copy of a Letter received from John Hill, Esq., Headstone Farm, near Pinner, Middlesex.—Sir,—Having been induced by your agent, Mr. William Stransom, of Uxbridge, to use some of your Guano manure, together with other sorts, and after careful application and watching, I must say yours has proved the most useful, and far preferable to the Foreign. My land is a strong clay. I should recommend it as a top dressing for Wheat, Grass, &c, to be used in the state you send it out, without any mixture, and to be harrowed in. The difference in the produce of Wheat where your manure and the others were used may be seen at my farm. I think it a duty to yourself and the public to state that I shall be happy to give any information as to how I applied it. Yours, &c. JOHN HILL.

Headstone Farm, near Pinner, Middlesex, Oct. 24, 1844.

To Frederick Brain, Esq.

N.B.—I shall try it this year drilled with Wheat

Price 9l. per ton. Sacks free of any charge, delivered free to any Wharf or Rail, in Town.—Works, Thomas-street, Duke-street, Stamford-street, Blackfriars-road.

Brain's Highly concentrated Liquid Guano, 1s. 9d. per Bottle, enough for 80 Gallons of Liquid Manure as usual. Of all respectable Florists, Seedsmen and Chemists, in Town and Country.

DR. HALLETT'S DRY SOLUBLE FERTILIZER'S are, considering their power, the cheapest Manures in use, for they are entirely composed of the Phosphates and other Salts of Ammonia, and other acknowledged powerful fertilizers. They are fairly before the Public as tried things (see No. 33 of the *Gardeners' Chronicle*, &c.). 5 cwt. of either has been found equal to nearly 30 tons of ordinary horse-manure. They are applicable to all sorts of field and garden crops. No. 1 for heavy top growth, as Corn, Hops, &c. No. 2 is for all roots, and a sure preventive of the Fly in Turnips. Price of each, 10l. per ton, or 12s. per cwt.

DR. HALLETT'S CONCENTRATED LIQUID FERTILIZER is extensively used by Gardeners for improving the size and flavour of fruits and vegetables, and the colours and perfecting the seed of flowers. Sold in quarts at 1s. 6d., and in bottles, six times the size, at 7s. 6d. Each quart requires 32 gallons of water, to reduce it for use.

Agents for the above. London—Mr. Fothergill, Thames-street; Mr. G. Hallett, the Factory, Broadwall, Blackfriars; Messrs. Warner & Warner, 28, Cornhill; Hurst & M'Mullen, 6, Leadenhall-street; Winstanly, Poultry; Pace & Co., St. Peter's Alley. Norfolk—Bullard and Watts, Norwich. Suffolk—Mr. W. Revans, Yoxford. Leicester—Mott and Co. Gloucestershire—Mr. Betterton, Fairford. Devonshire—Mr. Seward, Plymouth. Wilts—Mr. G. King, Devizes. Glasgow—Mr. D. T. Jackson, Hartlepool. Sunderland, Stockton, and Newcastle—Pace & Co. Dundee—Green and Co. Further respectable Agents wanted.

IMPORTANT TO AGRICULTURISTS, &c.

ANALYSES of SOILS, MANURES, and all AGRICULTURAL PRODUCTS, are conducted by Messrs. MITCHELL and FLETCHER, 32, Mitchell's, Analytical Chemists, with the view of ascertaining whether the Soil, in which it is proposed to grow any particular crop, contains all that is necessary to produce a luxuriant vegetation; also to estimate the relative value and purity of Manures, and the comparative worth of Farm Produce in general. Gentlemen instructed in Agricultural Chemistry. The course will comprehend the Elements of Analysis.—No. 5 A, Hawley-road, Kentish Town.

RAMS FOR RAISING WATER WITHOUT LABOUR, where a fall can be obtained. FOUNTAIN BASINS IN IRON, &c. 76, STRAND, LONDON.

F. ROE having purchased all the Patterns of Basins, Jets, &c. formerly belonging to W. Rowley, Fountain Maker to the Royal Family, is enabled to offer the above article in Iron, which will stand the Frost and last for ages. A Rose and Fountain fixed on the premises for inspection. Every kind of Garden and other Pumps, Well Engines, Baths, &c. Houses, &c. Heated by Hot Water.

SHEATHING AND DURABLE ROOFING.

BY HER MAJESTY'S ROYAL LETTERS PATENT.

TO GARDENERS, NURSERYMEN, AND OTHERS.

F. MCNEILL & Co., of Lord's Buildings, Bunhill-row, London, Manufacturers, and sole Patentees of IMPROVED PATENT ASPHALTED FELT, for Roofing Houses, Sheds, Verandahs, &c., and for Protecting Plants, and Covering Garden Frames, &c., is in all respects superior to Tarpaulin, and others to their superior article which has been exhibited at the Great Agricultural Shows of England, Scotland, and Ireland, and OBTAINED the PRIZE for being the best and cheapest article for roofing, &c. It has been used in the gardens of several noblemen and gentlemen in the neighbourhood of London, and in different parts of the country, to whom reference can be made. The Felt is impervious to rain, snow, and frost, and a non-conductor of heat and sound. Its advantages are Lightness, Warmth, Durability, and Economy.—Price One Penny per Square Foot.

Samples, with directions for laying on, and testimonials as to its merits, sent free to any part of the town or country.—Patent Felt Works, Lord's Buildings, Bunhill-row, London.

TO LANDOWNERS, HORTICULTURISTS, BUILDERS, &c.

MCMURRAY'S PATENT ROOFING FELT is peculiarly applicable as a substitute for Slate, Zinc, Tiles, and other articles used for Roofing, from its ECONOMY, LIGHTNESS, and DURABILITY.

The disadvantages attending other materials used for roofing, preventing, to a great extent, many useful houses and sheds being erected or rendered waterproof, it is submitted that the improved Roofing Felt will in a great measure—and in some instances altogether—obviate these, and prove most serviceable from its lightness, durability, and impermeability to water and damp, in covering Houses, Cattle-sheds, Workshops, Rose-walks, &c., and for the sides, as well as roofs, of light structures for plants, being likewise a non-conductor of heat; besides its economy in repairs, the material when required may be so light as to save its whole expense, it requires no other coping, and may be applied by any person of common ingenuity; being flexible and portable also, it is free from breakage, the expense of carriage is inconsiderable in comparison with slates, tiles, &c., and this article is recommended as

Sold in sheets 32 inches by 30, and in rolls (being less than 9s. 6d. per square of 100 feet), with printed directions for applying them, same as adopted at the Government Dock-yards and various other public buildings.

Orders will meet with prompt attention if addressed to H. C. BOWDEN, 18, East India Chambers, Leadenhall-street, London, or to the following agents:—Liverpool, Messrs. Gracier & Co., 11, Manesty-lane; Plymouth, Thomas Stevens, Esq.; Birmingham, William R. Loyd, Esq.; Sunderland and Newcastle-on-Tyne, Messrs. John Ritson and Sons; Bath, William Ward, Esq.; Bristol, Messrs. Moor and Hewitts; Ramsgate and Deal, Messrs. Edward Hodges & Co.; Whitehaven, William Todd, Esq.; Glasgow, Malcolm Carmichael, Esq., St. Enoch-square; Cork, Messrs. Richard Wallis & Co.; Belfast, Messrs. Graeber & Co., Dunbar's Dock; who have also on sale McMurray's improved SHEATHING, BOILER, RAILWAY, and other FELT.

*** The "IMPROVED ROOFING FELT" will be found much more durable than the Common Felt usually employed, and not subject, like it, or gutta-percha cloth, to rot or shrink, to be stripped by storm; *it does not require to be either painted or coated*, can also be more easily repaired, and from the simple mode of application recommended, the roof cannot percolate through nail-holes, being only fastened down at the overlaps.

LEA AND PERRINS'S WORCESTERSHIRE SAUCE. Prepared from the Recipe of a Nobleman in the County.

"*Great Western, Steam-ship, August, 1844.*—The cabin of the Great Western has been regularly supplied with LEA & PERRINS'S Worcestershire Sauce, which is in demand for every variety of dish, from turtle to beef, fish, game, and steaks, to all of which it gives a most delicious and piquant relish. We recommending this excellent sauce to Captains and Passengers, for its capital flavour, and as the best accompaniment of its kind for a voyage. (Signed) JAMES HISKEN."

"One of the most pleasing and refined amusements, luxurious and epicurean age is Lea and Perrins's Worcestershire Sauce, adapted to fish, flesh, fowl, and game, being a zest far superior to the long-established favourites, more wholesome and of less cost."—*Naval and Military Gazette, August 24, 1844.*

Sold Wholesale by the Proprietors, Messrs. LEA and PERRINS, Worcester; Messrs. BARCLAY, and SON, Farringdon-street; and the principal Oil and Italian Warehousemen in London; and Retail by the usual Venders of Sauces.

HARRY WALKER'S NEEDLES (by Authority the Queen's Own") have large eyes, easily threaded, (even by blind persons), and improved points, temper, and finish. Each paper is labelled with a likeness of Her Majesty or His Royal Highness Prince Albert, as relief, on coloured grounds. Every quality of Needles, Fish-hooks, Hooks and eyes, Steel Pens, &c., for shipping. These Needles or Pens for the home trade are sent free, by post, by any respectable dealer, on receipt of thirteen penny stamps or seventy shillings value.

H. WALKER, manufacturer to the Queen, No. 1 (late 20), Maiden-lane, Wood-street, London.

THE BEST ENGLISH WATCHES.—A. B. SAVORY and SONS, No. 14, Cornhill, and 9, Cornhill, London, opposite the Bank, request the attention of purchasers to their stock of London-made PATENT LEVER WATCHES, which are manufactured by them solely in their own house. In silver cases, with the strength and jewelled, the prices are four and eight guineas each; and eight guineas each; in gold cases, 10, 12, 14, and 16 guineas each. The very large stock offered for selection includes every description, enabling a customer to select that which is most particularly adapted to his own use.

STOOPING of the SHOULDERS and CONTRACTION of the CHEST, are entirely prevented, and gently and effectually removed in Youth, and Ladies and Gentlemen, by the occasional use of the PATENT ST. JAMES'S CHEST EXPANDER, which is light, simple, easily employed outwardly or invisibly, without bands beneath the arms, uncomfortable constraint, or impediment to exercise. Sent per post, by Mr. A. BENYON, 40, Tavistock St., Strand, London, or full particulars on receiving a postage stamp.

SUBSCRIPTIONS

TO THE

NATIONAL TESTIMONIAL

TO

MR. ROWLAND HILL,

AUTHOR OF THE PENNY POSTAGE,

WILL CLOSE ON THE 30TH OF NOVEMBER.

On all the sources of income stated in the recently published Quarterly Returns of the Public Revenue, none exhibit so large a proportionate increase as the *Post Office*. During the year's net Revenue, the Customs have increased at the rate of about 10 per cent., the Excise 4½ per cent., the Property Tax 2 per cent., while the *Post Office Revenue*, under its almost nominal rate of a penny, has increased above 13½ per cent., and the increase on the quarter alone been even as much as 23 per cent.

These startling results show that (though the *plan of Penny Postage* is yet but *imperfectly tried*) the *complete restoration* of the Post Office Revenue to its amount before the Penny Postage was adopted is not an event far distant, if it be fully and honestly carried out; and the *City of London Mercantile Committee on Postage* desire to impress these satisfactory results most emphatically upon the Public, in announcing the *approaching close* of the National Testimonial to Mr. Rowland Hill. *All* parties are unanimous upon the great *moral* and *commercial* advantages of the *Penny Postage*. Its expediency as a *financial* step has been the *sole* ground of question; but now, even this *can scarcely be doubted*: for, let it be remembered, that the Old Postage Revenue had been absolutely *stationary* for twenty years,—retrogressive, in fact, if we consider the increase of population, education, and commerce during the period. The change which Penny Postage has effected, is to make the *Post Office Revenue* the *most buoyant* source of National Income, bidding fair to become more profitable than it has ever been. The Committee, therefore, call upon the Public to *reward*, with suitable gratitude, the Author of this great and triumphant measure.

The Committee have the satisfaction to announce that the Subscriptions, headed by the chiefs of political parties and of commercial wealth, already reach 10,000*l.*; but 10,000*l.* cannot be held to be a sufficient *national* reward for such *national* services. The Committee therefore urge upon the *nation at least to double* the sum. If every letter-writer, for only a single week, would pay a twopence instead of a penny rate for his letters, the amount, and more, would be raised. In proportion as the public show their gratitude to Mr. Hill, so they strengthen the chances for the complete adoption of his plan, *now but partially carried out*, its perfection with Prize, greatly increased convenience to themselves, and increased advantage to the Post Office Revenue.

Never have the services of any *Public Benefactor* been requited as Mr. Hill's have been. Quitting a *permanent* situation for a *temporary* public engagement to carry out his plan, Mr. Hill's services, whilst his plan was yet not carried out, were dispensed with, and he received the following acknowledgments of his merits, and—*nothing more*:—

"I gladly avail myself," writes the present Chancellor of the Exchequer, "of the opportunity of expressing my sense of the satisfactory manner in which, during my tenure of office, you have discharged the several duties which have been from time to time committed to you." "I entertain," writes Sir Robert Peel (who has also subscribed 10*l.* to the Testimonial), "a due sense of the manner by which your conduct, in respect to Post-Office arrangements, has been actuated, and of the zeal and fidelity with which you have discharged the duties committed to you."—Mr. Trevelyan, on behalf of the Lords of the Treasury, writes thus:—"I am also commanded by their Lordships to take this opportunity of stating, that they consider it due to you, on the termination of your connexion with the Government, to express to you the approbation with which they have regarded your zealous exertions in the execution of the duties which have been intrusted to you; and how essentially the efficiency of the Post Office arrangements has been promoted by the care and intelligence evinced by you in the consideration of the various important questions which have been referred to you."

Under these circumstances the Committee call upon the *Public* to come forward with due generosity, and reward Mr. Hill themselves, as his *unrequited Inventor* of the *great measure of Penny Postage*—a measure which has opened the blessings of free correspondence to the Teacher of Religion, the Man of Science and Literature, the Merchant and Banker, to the *whole British Family*, especially the *poorest* and most *destitute* portion of it,—a measure which is the *greatest boon* conferred in modern times on *all the social interests of the civilized world*, for Penny Postage is spreading its influences throughout Europe, and reaching even Russia. The Committee rely on the *generosity* of their countrymen, and feel sure that this, their last appeal, will not be made in vain.

(Signed) GEO. LARPENT, *Chairman.*

Subscription Cards, and every information, &c., may be obtained on application to the Secretary, Mr. GEORGE WARRY, Solicitor, 3, Moorgate-street, London.

THE CONVICT [illegible]

JOHN DICKSON, Acclimatise, Brixton, Surrey, has prepared for the growers of these splendid flowers a Catalogue, enabling them to judge of their qualities, with the prices annexed which may now be had at the Nursery, and of Messrs WARNER & WARNER, Cornhill, London.

EXHIBITION OF CHRYSANTHEMUMS

CHANDLER AND SONS, NURSERYMEN, Vauxhall, London, beg to state that their Collection of this beautiful autumnal Flower is now in bloom, and will continue for the next two or three weeks

C and Sons have now on hand healthy young plants of Double CAMELLIAS of sorts, with flower buds, at 30s per dozen, larger plants, 42s per dozen, and young plants of the newer sorts, at 60s per dozen Package included in the above prices

"GENERAL TOM THUMB" SCARLET PELARGONIUM.

PHILIP CONWAY, NURSERYMAN & FLORIST, &c, Old Brompton, through the kindness of Mr. Ayres is enabled to let out a few plants of the above, which is thus described in the *Gardeners' Chronicle*, page 550 —

"Unquestionably the finest Dwarf Pelargonium out is that which has this season been exhibited under the name of 'General Tom Thumb' It grows almost prostrate, is exceedingly rich and dense in foliage, and produces with the greatest profusion large trusses of the most dazzling scarlet flowers imaginable I have a plant at this moment nine inches high and six feet in circumference, studded with 27 trusses of expanded bloom, and some of the trusses six inches in diameter; and on five plants there are upwards of 130 trusses of flowers"

For both pot cultivation and bedding out this plant is unequalled Plants 2s. 6d. each, or 25s per dozen, with the usual discount to the trade if six are taken at one time N B —At the June Exhibition of the Regent's park society a prize was awarded to the above, also to the following desirable variety of scarlets, viz. —

Frost's Superb, a splendid pot plant . 2s 6d
Mrs Meyler, a very fine new variety . 2 6
Cooperii, dwarf, for bedding . . 1 6
Huntsman, ditto . . . 1 6
Shrubland . . . 1 to 21s.
Compactum . . . 1 6
King . . . 1 6
Queen . . . 1 6
Conway's Giant Cactus, strong plants 2 6 to 10s. 6d.
Veronica speciosa . . . 2 6
Pelargonium Lanell, for forcing . . 1 0 to 2s. 6d.

Cash, with an order, is respectfully requested from unknown correspondents.

RICH LEAF-MOULD and PEAT-EARTH.—Several acres of valuable Peat-earth and Leaf-mould of a rich quality, to be disposed of. Gentlemen and Nurserymen, engaged in the Cultivation of Heaths and American Plants, will find the above articles of a very superior kind. Turf may also be found of great value, containing many Heath plants. The Estate is within one mile of the Thames, and has every water carriage. For full particulars apply to Mr. [illegible], Corn Chandler and Seedsman, No. 14, Fleet-street.

THE NEW AND SUPERB SEEDLING PICOTEE, "BURROUGHES'S DUKE OF NEWCASTLE."

For particulars of the above, see YOUELL & Co.'s Advertisement of October 12th.

YOUELL AND CO. are also enabled to supply the following superb Picotees, raised by the same gentleman, all possessing first-rate properties, which have been exhibited and obtained first class prizes at several of the metropolitan Exhibitions of the present year. They are as follow —

Burroughes's Mrs Benyon, Red Picotee . 7s 6d
" Lady Alice Peel, Rose Picotee 7 6
" Miss Jane, Purple Picotee . 7 6
" Mrs. Bevan, Red Picotee 7 6
" Enchantress, Scarlet Picotee . 5 0

CARNATIONS AND PICOTEES.

Y. and Co's collection of this beautiful tribe of flowers will be found the most extensive and select in Europe, comprising every known variety of merit. The plants are remarkably strong and healthy, and ready for sending out to any part of the United Kingdom and the Continent at the following prices

				£	s.	d.

Tigridia Pavonia, extra fine Dutch Bulbs " 2 6
Fine mixed Tritonias, p doz 2s 6d, mixed Ixias " 2 0

JAMES CARTER, Seedsman and Florist, 238, High Holborn, London

A SPLENDID NEW LATE PEACH.

MORTON'S "WALBERTON ADMIRABLE."—This splendid variety was raised at Walberton House, in Sussex, the seat of S. Prime, Esq It is a Seedling from the Noblesse, which it much resembles, both in size and colour It possesses all the fine qualities of its parent, but its great merit arises from its ripening full five weeks later. A specimen of its fruit was sent to Dr LINDLEY in 1841, from whom were received the highest testimonials of approbation. The tree is a fine, free, and hardy grower; the fruit is full-sized, melting, and excellent-flavoured, rendering it a truly desirable variety, and one which no good garden ought to be without Good one year's trained plants can be obtained of ALEXANDER WEBB, Nurseryman, Westergate, near Arundel, Sussex; at Messrs HAY, ANDERSON, and SAUNDERS's, Newington Butts; and also at Messrs. HUNDT and M'MULLEN's, 5, Londenhall-street, London, at 10s. 6d. each; a few strong plants at 15s. each. The usual allowance to the Trade when three or more are taken, and carriage paid to London. Remittance from unknown correspondents is required.

NORTHWARNBOROUGH & BARTLEYBOW NURSERIES ODIHAM, HANTS. EXTENDED OF FORTY ACRES, ESTABLISHED MORE THAN ONE HUNDRED AND FIFTY YEARS.

THIS BEING THE SEASON for Planting, J. and J. GRIFFITHS beg to call the attention of the public generally to their Nurseries, which are well stocked with every description of Forest-trees, Conifers, Flowering shrubs, and fruit trees. And more especially do they invite attention to their Fruit-trees, which are three years standard, well-rooted, and fine trees. Every tree, for which and espaliers alone, more than Ten Thousand grow.

TO THE CULTIVATORS OF ROSES.

R. B. BIRCHAM, Hadenham Rectory, Bungay, Suffolk, begs to offer the following choice PERPETUAL ROSES Good dwarf plants, own budding, suitable for pot culture or transplanting into the open borders.

Aric e . . .	2s 6d.		Anémone . . .	1s. 6d.	
Auburnon . . .	2 6		Alfred . . .	2 6

Cloth of Gold (Noisette) strong plants, 7s. 6d.

Choice Roses selected from various classes —Dwarf Standards, 12s per dozen, do, superior kinds, 18s.; Standards, 18s. per dozen, do, most superior, 30s.

A descriptive Catalogue sent on application Plants gratis, to compensate for distant carriage.—Hadenham, Nov. 8, 1844.

PLANTING SEASON.

W. ROGERS AND SON, NURSERYMEN, CONTRACTORS PLANTERS, & LANDSCAPE GARDENERS, Southampton, beg respectfully to notify that their Nursery Stock is this season unusually fine, and from the extent of their grounds they are enabled to execute orders to any amount, and at the lowest price, delivered free of carriage (if ordered in quantity) per railway to London, or by steam vessels coastwise.

SEEDLING.

Ash, 1 yr, 1s 6d, 2 yrs, 2s 6d	Spanish Chesnut, 1 yr., 10s.		
Beech, 1 yr., 2s.	Pinaster, 1 yr., 2s. 2d., 2 yrs., 3s. 6d.		
Birch, 1 yr 2s			
Sea Pine (Pinus maritima), excellent for nurses or exposure to the sandy sea shores of Scotland or Ireland, 1 yr., 5s., 2 yrs., 7s 6d per 1000			
Oak, the true "Durmast" of the New Forest (Quercus sessiliflora), producing timber of the largest dimensions, and decidedly the most valuable species of the English Oak; 1 yr., 7s 6d, 2 yrs 10s., 3 yrs 13s. per 1000.			

TRANSPLANTED.

Prices and samples of the various sizes may be had on application.

Alder . . .	1	2	3 ft	Oak, Durmast, English .	1	2	3 ft.
Beech . . .	1	2	4 ft.	Turkey . .	1	2	3 ft.
Birch . . .	1	2	4 ft	Spruce . . .	1	2	4 ft.
Ash . . .	1	2	3 ft.	Larch . . .	1	2	3 ft.
Spanish Chesnut	1	2	6 ft	Scotch . . .	1	2	4 ft.
Elm . . .	1	2	3 ft	Pinaster . .		1	2 ft.
Poplar, Blk Canada	2	4	6 ft	Sea Pine . . .		1	2 ft.

If 100,000 of any one sort is ordered, a deduction from these prices will be made.

PLANTS FOR COVER OR UNDERWOOD.

Rhododendron ponticum, 1 to 2 inches, transplanted, 20s. to 30s per 1000 Not subject to the depredations of game.

Ditto, 2 to 4 inches, 40s. to 50s., 4 to 6 inches, 60s. to 80s; 1 foot, 25s. to 100 Not subject to the depredations of game.

Mahonia aquifolia, 40s per 1000. Game are remarkably fond of the fruit of this plant, which is also a handsome flowering Evergreen

Common Laurel, 20s. to 40s. per 1000.

Come-well Willow, 40s per 1000. Best for Underwood.

Furze, 10s. per 1000. Broom, 10s. per 1000.

Alder, common black, 8s. per 100. Excellent for sea-embankments. Tamarisk, 8s. per 100

MISCELLANEOUS.

Single Camellias, from pots, well rooted, 30s to 72s. per 100

Rose stocks, 8s per 100, from cuttings of the Bourbon De Lisle, on which all kinds take freely by buds and grafts, and may be grown in the smallest sized pots.

Double Furze, 25s per 100 Forms a beautiful flowering hedge.

Double Red Thorn, Double White do., Single new crimson, 50s. per 100. Sea Pine, from pots, 40s per 100.

Ribes sanguineum 12s 6d per 100

Printed Catalogues of Prices of their general stock may be had. Gardeners of experience and ability recommended.

FASTOLFF RASPBERRY.

JOHN BELL begs to inform his Friends and the Public that he has grown the above Raspberry extensively the last three years, and has now a fine stock of strong Canes, which he intends offering at the following prices, carriage paid to London and Hull, when 100 Canes are taken.

100 Canes .	1l. 15s. 0d.—package included.			
50 " .	0	17	6	"
25 " .	0	9	0	"

J. B. living in the neighbourhood where the above Raspberry has been cultivated for many years, can warrant it true. It may also be had of Mr. CATLEUGH, Nurseryman, Hans place, Chelsea; and Mr. NUTTING, Seedsman, 44, Cheapside

Nursery, Bracondale; Seed Warehouse, 3, Exchange street, Norwich.

WM. STIDOLPH, NURSERYMAN, near the Plough Inn, Bromley Common, Kent, begs to offer for Sale 4000 Spanish Chesnuts, 2 to 6 ft., 5000 Ash, 4 to 7 ft., 1000 Laurels, 4 to 5 ft, Spruce Firs and Weymouth Pines, 5 to 8 ft., Yews, 6 ft. and upwards, Rhododendron ponticum, 2 to 5 ft., flowering plants; Portugal Laurels, 3 to 5 ft., Purple Beech, 5 to 6 ft., Oaks, Elms, and Horse-Chesnuts, 12 to 16 ft., Privets, Laurustinus, &c. &c.

SHILLING'S EARLY POTATO PEA.

THE above PEA is a Grosvenor over every other for autumn sowing, being quite as early, very prolific, and much larger than any other early Pea. See *Gardeners' Chronicle*, 25th of last May. "Mr. Shilling has sent us specimens of his New Early Green Pea, which were gathered on the 26th inst. He states that these were produced from seed sown in the open ground on the 15th of last November. Judging from the specimens sent, this is a fine, large, good-looking Pea, and will, no doubt, be found to be a very useful early variety."

To the Market Gardener they will be found invaluable. Price 1s. 6d. per pint, 10s. per peck.

SHILLING'S DWARF TADPOLE, which gave such general satisfaction last year, is the best early variety grown. Having saved a considerable quantity of seed this season, it is offered on the same terms—1s. 6d. per pint, 10s. per peck.

Seedsman to the Royal Horticultural Society, Field and Onion Ground, 19, Lower Thames-street, London Bridge. Retail Shop, 150, Fleet-street; 1, Nobie-street, Milton-street; and 2, Nobie-place, Cowgate, Edinburgh. Agents—Messrs. Rollo and Ramsay, Edinburgh; Messrs. Hurst and M'Intosh, 6, Haddenhall-street, Covent Garden

THE TRUE FARTOLFF RASPBERRY.

YOUELL AND CO. take the present opportunity to state that the above unequalled Raspberry is now ready for delivery at their Nursery or of their Agents. A list of Agents will be given in the Advertising Sheet of this Paper next month, at which time they recommend their friends to send their orders early, that they may be executed in rotation, as another Fruiting season has passed since the Fartolff was first introduced, and has been substantiated by hundreds of the first cultivators.

Great Tarbuton Nursery, Nov. 7, 1844.

TULIPS, HYACINTHS, RANUNCULUSES, ANEMONES, GERANIUMS, AURICULAS, CARNATIONS, and CALCEOLARIA RANCHOLIUM.

H. GROOM, Clapham Rise, near London (removed from Walworth), by Appointment Florist to Her Majesty the QUEEN, and to His Majesty the KING OF SAXONY, begs to recommend to the attention of the Nobility, Gentry, and Public his extensive assortment of the above flowers, which, from the unusual care he has had in their cultivation, he can offer at very moderate prices. He particularly wishes to call attention to the many interesting varieties in his collection of Tulips and Hyacinths, which this season, in the various papers, he so much admired—reminding the Nobility, Gentry, and Amateurs, who may wish to add to their collection or ornament their parterres with these beautiful flowers, that this is the best season to make a selection. The varieties of the splendid Liliums candidum are particularly adapted for parterres, as, besides being quite hardy, they flower at a time when the Nobility and Gentry are at their country seats, and when flowers are so much wanted. They only require to be known to be universally cultivated. Catalogues can be forwarded by post on application. Foreign orders executed.

The Gardeners' Chronicle.

SATURDAY, NOVEMBER 9, 1844.

MEETINGS FOR THE TWO FOLLOWING WEEKS.

WEDNESDAY, Nov. 13 - Meteorological . . . 8 P.M.

SATURDAY, Nov. 16 - Royal Botanic . . . 4 P.M.

We have been surprised of late to perceive that an influential part of the daily press has thought fit to urge objections against the systematic continuance of AGRICULTURAL AND HORTICULTURAL SOCIETIES, on the plea that they do not effect any substantial advantages among the practical classes of farmers and gardeners; that competitions between mere *amateurs* produce no beneficial results to those who live by husbandry, or cultivate market-gardens. If an enormous prize ox be fattened by the nobleman's bailiff, it is said that the cost of bringing him to the high condition in which he is exhibited to public admiration is more than the value of the meat in the market; that wealthy proprietors only can afford to amuse themselves thus, because they have means and facilities beyond the reach of those humbler individuals for whose benefit the Societies to which we are referring are professedly embodied. Nothing can show a more entire ignorance of the true bearing of such associations than such crotchets as these.

Every intelligent farmer and gardener knows that the range of experimental investigation in his department is almost boundless; and he finds that each revolving year adds to his practical, if not to his theoretical knowledge. He knows, too, that the prize ox has not been brought to his high condition without great attention to the most improved routine of husbandry in all its bearings. The culture of green crops in a corresponding degree of excellence with that of large cattle reared and fattened for the shambles is to be attained; and in order to have abundant and superior green crops, white crops must be proportionably raised. Manure cannot be abundantly accumulated without cattle, nor cattle littered without straw: one branch of farming thus necessarily involves the necessity of another, and within a very extended and comprehensive range of perfect or very superior husbandry, as pursued on the demesne of the wealthy proprietor, or the great farm of a rich and intelligent tenant, who follows the profession by which he lives with energy and enthusiasm, a vast variety of improved details is involved, among which the common farmers and peasantry may assuredly find something worthy and easy of adoption. It is also of great importance to have experiments conducted by those who can afford to make them without regard of the loss in case of failure; and unquestionably the desire of obtaining distinction for skill and perseverance, the ready promotion of useful knowledge stimulates to competition, while the honorary prize, which is the testimonial of merit, costs the Society which awards it little or nothing.

The presentation of a single medal has often led to movements in husbandry which have afterwards advanced to points of great importance. If recent instances be of any value in illustration of this remark, we would adduce the great extent—great in comparison with previous efforts—of thorough-draining executed last year, in Ireland, by four spirited proprietors, who, however patriotic and enterprising they may be systematically, as improvers of land, would not, in all probability, have completed so great an extent of draining without the agency of the Royal Agricultural Society of Ireland, which stimulated their energies by proposing a prize to the successful competitor in that important branch of improvement, to which attention has been much turned of late years, and in the advancement of which Mr. Smith has acted so conspicuous a part.

It surprises us to hear any persons attempting to throw discredit upon Societies which are formed on sound principles, and for philanthropic objects; and deliberately effecting it on grounds which are not always perfectly understood, either in object or detail, by those who think fit to denounce them.

It is a very desirable matter that the aristocracy of any locality should take a deep and practical interest in agricultural and horticultural occupations. The sports of the field, though possibly necessary for the health and recreation of idle country gentlemen, and certainly great inducements to their residence on their rural estates, are often interrupted by unpropitious weather; and the extravagant amusements of the *turf*, or of the silly and cruel steeple-chase, are at best but brief periodical excitements, which are often seriously depressing in their consequences to the overworked mind, and exhausting to the purse, while they tend to render the human heart as callous as the whip or spurs in which the jockey glories. The individual whose horse is to run for the high stakes of a celebrated race, has nervous sensations unfelt by him whose cattle quietly contend in the ploughing-match; and surely, in point of utility, there is no room for disputation as to the comparative advantages of the different pursuits.

Then as to gardening—Where can there be found more innocent or interesting employment of the active kind, or which tends more, when scientifically conducted, to elevate and expand the mind? What relaxation for the saddened or fatigued spirit can be named, that is more calculated to soothe and relieve it than occupation in the greenhouse or the open garden? And if idleness oppress—if the miserable sensation of a want of something to do renders the fine lady or fine gentleman listless, where can a more pleasing excitement to thought and gentle exercise be found, than in the garden and shrubbery? Nor is this pleasure occasional and evanescent—it may be enjoyed at all times; and the most delicate female can never be without inducement to inhale the free air of heaven—so essential to the preservation of her health and beauty—while she has her flower garden and conservatory to visit and arrange. In short, the possession and management of a well-ordered farm and garden is a point of attraction to our gentry, and if they can support the expense of maintaining first rate bailiffs and gardeners, who can win prizes in their respective departments, they not only encourage a class of men whose occupations are pre-eminently useful and pleasing, but they become the means of imparting to the inferior grades of rural occupiers, that desire for acquiring good skill and taste in the management of their humble allotments, which so decidedly tends to advance their condition. Although there may be occasional ground for dissatisfaction at the supposed ignorance or partiality of Judges in the distribution of prizes (we are now alluding more particularly to the Horticultural Shows), and that feeling of jealous rivalry which mean minds so frequently entertain, with or without reason, still the principle of competition is useful. People of sense not only bear disappointments with a good grace, but feel a generous pleasure in seeing displays of finer plants than they themselves possess, and instead of grumbling at everything which has not been exactly in accordance with their own views and caprices, determine to persevere steadily in their efforts, being quite content to witness the progress of the art which they admire, without experiencing any mortification at their own failures, and very happy to see rich and poor assembled together for the enjoyment of a pure and rational pleasure. Then, when an ardent florist exposes to the scrutinising examination of experienced judges some splendid flower which he has raised himself, how happy is he! How he contemplates his admired specimen! with what satisfaction he criticises its form and colours! He pets it as if it were his child; guards it "lest the winds of heaven should visit it too roughly;" gives it air, and warmth, and nourishment suited to its condition and necessities; watches over its growth, with the certainty of receiving no ungrateful return for his care. All this is at least harmless enjoyment, gentle and soothing, and such as never costs a tear of mortification or regret.

And who that has a heart will not experience more genuine delight in looking at the collection of choice flowers than in viewing an extravagant display of expensive dishes and of labelled decanters upon his table, for the entertainment of people who do not care one farthing for their entertainer?

And who that sees the beautiful specimens of new varieties, which the tasteful gardener perpetually raises, as much from the influence of professional spirit as from the love of his art will say that the Horticultural Show is useless, or that the art of gardening can go no further? Let us just first reflect on the advancement which has been effected in the culture of the Pelargonium, for no plant has been more varied within 20 years; intelligent cultivation has wrought the most surprising changes, and produced a most wonderful number of varieties in this beautiful flower. The flower, has been enlarged, the colours, infinitely diversified, have passed through successive gradations from the purest white to the deepest shade of black. The beautiful plant which, during half the year, ornaments the drawing-room or the conservatory, owes its pre-eminence to honourable emulation. Again, in the tribe of Roses—of which more than 2000 varieties exist—there were, not five kinds known 160 years ago in France and England; and when a sixth was imported into the former country from Italy, for the first time, all the world of florists went mad to obtain it. When Linnæus published his "Species Plantarum," in 1753, there were only 14 kinds of Roses known, and now there are more than 2000. What but the spirit of competition has effected this enormous increase? What but emulation produces, every season, some new sorts by budding and grafting, which bring forth the innumerable hybrids of the Rose tribe? And though some old-fashioned florists may complain that caprice and fickleness, which operate more or less in all human affairs, have caused results not altogether legitimate in the royal family of Roses, both red and white, by substituting the younger scions for the older branches, bringing into popular favour the hybrids of yesterday, we cannot but think it is no small advantage to have obtained plants that, unlike the old parent stock—which, no doubt, was very respectable in its day—will exhibit animation throughout the year, though their flowers be deficient in the odour and excellence of the ancient family.

We know that some humbug is occasionally the result of a successful hit at a Prize Show of Flowers, but it is not of any serious consequence, nor can it in these days, when there are so many professional rivals in the floral department, affect the pocket of the amateur to any sensible degree, as might have been the case in the days of the Tulip mania, when Hollanders made fortunes by a few of the rich plants of their country. For example, a specimen of the Pansy is honoured with a prize at Chiswick, or some other great National Exhibition, and the happy owner advertises his spare plants of the favourite kind at a very high price compared with their real value, but low in itself, and a mere trifle for a *fancy* article, and such as no amateur will consider a drain from his purse, while the payment of it tends to encourage the gardener who lives by his occupation. In fine, whether the vegetable productions encouraged at our Horticultural Shows be Pines or Potatoes, Cauliflowers or Carnations, Parsnips or Pansies, we wish success to those who deserve it in their respective classes, whether the claimants be Peers or Peasants, or of the more really intercated grades—those in middle life.—*Martin Doyle.*

REMARKS ON FORCING PEACHES.

[See page 707].

In answer to "A Subscriber," regarding the temperature, &c. at which I force my Peaches, I may mention that, as I am obliged to force them in the Pine-stove, having no intermediate house for that purpose, I am, therefore, under the necessity of keeping a higher temperature at the commencement than I otherwise would do if I had a Peach-house to begin with.

The house in which I force my Peaches in pots is a large one, constructed of Iron. I grow Grapes up the rafters, and Pines in the pit. The house is heated by common flues, with two 4 inch hot-water pipes going round one end, and along the side of the front flue. The fire, after passing round the boiler, enters the bottom of the back flue, which is a double one, and returns by the top flue, escaping in a chimney over the boiler. On the top of the back flue I place as many trees as I can conveniently, and on the back curb and end curbs of the Pine-pit I put the remainder. By this means it will be seen that the Peaches are not in the way of the Pines, as you can walk along the back passage between them. The Vines are confined to the rafters, and no useless wood is allowed to remain on them that would tend to shade the leaves.

When I commence forcing, I endeavour, if possible, to bring the trees into the house in mild weather, there being much less difference then between the temperature of the internal and external air; I generally put them in during November, a little earlier or later according to the state of the weather; I do not start them all, however, at once, the last lot are not put in until the 1st of January. Any later than this would not answer, as the weather, if clear, is then hot through the day. I commence forcing them at 55° at night, allowing the thermometer to fall to 50° in the morning, if cold, but, if the weather is mild, it is never allowed to fall below 55°, and from that to 60° is the usual temperature kept up throughout the period of forcing during the night. It is during the day that I make up for low night temperature, that is, when I have the chance by sun heat. On the second day after I had brought my trees in-doors last year, the temperature of the house was 80° for two

hours during the middle of the day. Now, those who are accustomed to plod on from November to the latter end of June will think this a strange way of forcing Peaches: but the fact is, if I can get sun heat, I am not at all fastidious about a few degrees; to get it high enough is the main point—say from 70° to 85° and 90°, until the fruit is stoned; I then keep them very hot during the day—viz., from 90° to 105°, and sometimes even as high as 110°. Of course a great deal of moisture is required with this high temperature; a moist atmosphere is congenial to both Vines and Peaches. I syringe over head twice a day, and sometimes oftener, when the air is dry; and the consequence of this treatment is, I am scarcely ever troubled with either green-fly or red-spider.

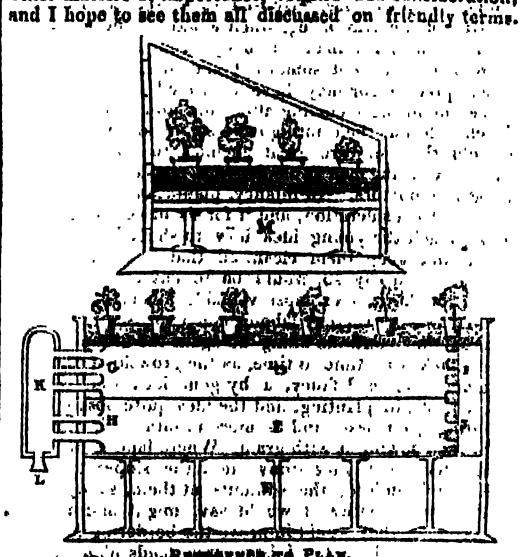
Watering at the root must be carefully attended to; very little is wanted until the trees get covered with leaves; but after the fruit is stoned, they should be watered plentifully, if you wish to have good fruit. Of course the watering must be gradually withdrawn as the fruit approaches maturity, in order to increase their flavour.

The following objection has been offered against early forcing of Peaches, viz. that they can have no flavour at that early season; but the fact is, to grow the trees in pots is the only way to have the fruit well flavoured, as the roots are then completely under control. Some say that I will soon lose all my Vines by the high temperature at which I keep the Peaches; but these persons do not consider that I am taking the very best plan to make my Vines grow, by treating my Peaches in the manner above stated; and I invite any one to come and see my Vines and Peaches growing together, when they can form their own opinion of the matter.

Now, with regard to the trees, unless they are prepared for forcing, you have no right to expect fruit in April; but if you think otherwise, try. Maiden plants are the only ones to begin with. Pot in as small pots at first as you can, and cut down to four or five eyes; shift every year, shaking off a little of the old soil. In May last, I saw some as fine maiden Peach trees in pots, in one of the London nurseries, as I could wish to see; and any one buying a few trees in the same condition would save a year's labour. They were making fine shoots in May last.—*W. Hopkinson, Bulmpton Park.*

THE TANK SYSTEM OF HEATING.

THIS, for furnishing Vine houses, Melon and Cucumber pits, and all structures for plant-growing, with bottom heat, instead of underneath and unsightly fermenting materials, is one of the greatest boons for simplicity, utility, and economy in horticultural purposes ever yet acquired, and undoubtedly claims the praise and due consideration of every individual who wishes to see the truly interesting science of Horticulture improve and keep pace with the spirit of the improving times in which we live.



I would recommend all scientific and practical men to give the subject due and serious consideration: they should well discuss it in their own minds as well as publicly with others: in time much information would thus be gained; for amongst "a multitude of counsellors there is wisdom." There are several very essential points requiring serious discussion and due consideration, before the great advantages that are to be derived from this system are to be gained, such as, What are the best materials with which to construct those tanks, in order that they may answer all purposes in the most economical manner? What is the depth of water that should flow, so as to command the most kindly and uniform heat? What is the best mode or proper system for the water to flow from and return to the boiler? Which is the best-constructed boiler from which to obtain the greatest advantage in regard to regularity and economy? These, with some other items, require due consideration before introducing the tank system. They are most important questions. Some tanks are constructed of wood, cased or lined with zinc or lead; others are made of stone, bricks, tiles, and slates, cemented together, and in not a few instances they are formed with such solid walls and foundations of masonry, that it only requires a second thought to perceive the great loss of heat that must take place on account of the absorption of such materials. Again, all the above-mentioned materials are in some degree liable to get soon out of repair, and this may happen at the most critical season. Bad materials, or imperfect workmanship, &c., are apt to cause leakages, and in many cases these tanks are so constructed that it is no easy matter to discover where the imperfections are, so as to get them put again in repair. I shall not attempt to condemn those structures or their materials, but I must acknowledge I cannot highly recommend them without considerable alteration. Under all circumstances, even with my limited practice, I can see no material at the present time so likely to answer all purposes with the greatest advantage as cast-iron tanks, constructed on a good principle. The sides of the pit for holding the plunging materials over the tank might be of the same material, which could be cast plain or ornamental, according to taste, and if it were kept nicely painted it would have a very light and neat appearance; the whole might be carried on cast-iron supports, and placed upon a good base, with flag-stone under the iron support, which should be cast with a good broad base, similar to those in use for supporting corn-stacks, &c. The advantage of having tanks constructed in this way will be at once obvious. 1st. They will be neat and durable. 2d. There will be great advantages gained by the tank being thus made to assist in heating the atmosphere of the house, pit, or other building. This heat is in too many instances entirely lost to all useful purposes. 3d. There will be considerable heat given off from the bottoms and sides of tanks on the above principle, that will warm the atmosphere of the house. Another considerable advantage gained by setting a tank open and free on iron supports is, that there will be nothing to prevent water or air from circulating freely in all parts of the house. The most present structures admit of but a very unequal circulation of heat and air, as is very obvious to most practical men. Underneath this tank there would be both light and air, and the space would be found useful for growing early Cauliflowers, stock-plants, starting various kinds of bulbs, Dahlias, or early Potatoes for growing in pots, or for turning out into pits for forwarding; and many other things could in such a situation be forwarded. The iron supports could be cast square, as a sliding shutter could be fitted closely and neatly to them, to be taken in and out; they should be provided with ventilators at the top, or one opening a few inches in depth might be continued the whole way round, by which means the free circulation of heat and air would not be impeded. A famous situation might also here be formed for growing Mushrooms during the dark winter months, as well as for forcing the first crop of Sealkale is river, sea, or other sand, or in old tan, at the season when it is not an easy matter to get it out of doors, on account of bad weather. I have found no difficulty in producing it in good perfection in a similar situation during the last three winters. This would likewise be found an excellent situation, when left quite open, for producing the first crops of Asparagus in November, December, and January. Thus, by foresight and persevering attention, the space underneath the tank could be made to produce various useful articles, that would go far towards defraying the expenses of fuel, where the tank is introduced on a good principle.

In pits and frames where there is no walk inside, but where what is required to be done is performed from the outside, as is generally the case with such structures, I should recommend that the tanks be borne on supports in the same way as above described, leaving a cavity of a few inches at the outside of the pit that contains, or should contain, the plants, fruits, &c., and the outside wall, which should be provided with ventilators, placed at intervals, for the purpose of admitting air both below the tank and above the pit. This would keep up a free circulation, and the air could be admitted either from one side or from the other, according to the state of the weather, or other circumstances: it could also be admitted at bottom or underneath the tank, and at top. By this means damping or fogging off, as it is termed, blenching of plants, or any difficulty with regard to starting into fruit Pine plants when grown to maturity would never be heard of: cleanliness, health, and vigour would be obtained.

Some have formed this idea, and have actually put it in practice, viz., that when they obtained the tank, they had no further need for flues and pipes for heating the atmosphere of their houses and pits, thinking that the tank would furnish all that was requisite. In some degree the system I am now pointing out would effect that object; more particularly in the case of pits, which can be covered in bad weather. At the same time, even for pits, however, I would recommend that a flow and return pipe be always at the front; it need not be made use of except when it is requisite; no waste whatever would occur, the expense of pipe not being great. The command of pipes will be found useful in any structure when damp and foggy weather prevails, to dry up the moisture by turning on a little heat and giving air. How practical men can depend entirely on tanks, under the present mode of making them of solid walls and masonry, when so large a portion of heat is lost by being buried and absorbed, I am at a loss to guess. Surely this has not been duly considered. It is true that they may have gone on tolerably smooth and comfortable, and may have been able to obtain a sufficiency of heat during the last twelve months of fine weather: such a season we may never again see. But even under these favourable circumstances, I am doubtful if the required atmospheric warmth could at all times be fully maintained, without imposing a very unnatural bottom-heat for the plants, at the very time they required the most uniform temperature. Why should we dispense with the means at command for warming the atmosphere, because a great improvement is discovered for furnishing the required bottom-heat? While such things are kept in practice, I shall not be surprised to hear of much prejudice against the tank system. Does it not look very much like imposing on a good object, to rob it of its greatest merits? Allow nothing to be wasted—act in all things with some little foresight and judgment—and with the greatest possible economy under all circumstances; but do not draw your beverage from the spile-hole, and allow the greatest quantity to waste by the bung-hole. I have been a practical gardener for years before boilers and hot-water pipes were much used for gardening purposes; and have seen the great opposition and prejudice they met with in many localities, when they were first introduced for heating garden structures; they are, however, now happily sought after as much as they were then opposed, and a gardener now would be thought as far wrong in choosing a fire-flue for a hothouse or pit, in preference to boiler and pipes, as a courier would be in selecting an old hackney coach for travelling with expedition, in preference to the Great Western Rail.

Boilers have been made of almost numberless shapes and sizes, from the size of a man's hat to that of a large brewing-copper. Those constructed some time since were so unwieldy that they took an immense quantity of fuel and patience to heat them, and after all they did not maintain the good qualities they were said to possess, viz., superiority to others in keeping a more regular and uniform heat, when once made hot. It was forgotten that there was the same body for the cold to act on, as there was for the heat. These persons of my acquaintance lost their lives by falling into those dangerous boilers, while adjusting and regulating the unnecessary apparatus then in use. In these times the more mysterious the construction of a hot-water apparatus, the more clever and more scientific the inventor was generally considered. Those ideas, I think, however, seem in a great measure to have blown over; but still there are some such ideas yet put into practice, or why should men recommend a large body and depth of water to flow through a tank, in preference to a quick and uniform shallow flow and return? This is a point that requires discussion. Let us consider this subject rationally and not falling back to the olden times, but commencing with the practically known and most proved system now to us, recollecting that we have but a short journey to travel, and that it is our duty to go through with it in the nearest way on the most friendly and neighbourly terms. Boilers of many shapes I have practised with; but I must acknowledge that three in use here at this time, constructed and used by Messrs. Garton and Jarvis of Exeter, possess great and superior advantages over all that have hitherto come under my notice; the last constructed one is still an improvement on the others. Tanks, I conceive, in order to obtain an advantage over those at present in use, should be double; that is, they should have two floors, one above and another below—the top floor, of course, taking the flow from the top of the boiler through the whole width and length of tank, passing over the opposite end, and returning by the bottom floor again to the boiler. The number of flow-pipes from the boiler may be regulated according to the extent and width of tank floors. I imagine that it would be of advantage to provide two flows to every tank above 4 feet in width; when three or four could be just as easily provided for tanks from 6 to 10 feet in width.

In the next age practical men will laugh and wonder how we expected anything like a kind and uniform heat from fermenting materials; and will then know how to turn those materials to better account, which are now to such an extent wasted. All tanks should of course be provided with ventilators, not for allowing the escape of evaporation, which should not be allowed by any means, but for the purpose of occasionally cleansing them out. And all pits, &c., provided with tanks that have no walk inside, should be provided with ventilators and trap doors large enough to admit a man to go underneath to paint, examine, and repair any imperfection, &c., that in time might happen. The best constructed pits—the best plunging materials—the best and most natural provision for turning plants out of their pots—and several other matters of importance, require due consideration, and I hope to see them all discussed on friendly terms.

C Coarse rubble underneath the plunging material, for the due circulation of air, heat, and water—one of the most essential provisions in the whole structure.
D Upper flow-floor.
E Under, or return-floor.
F Iron standards for carrying the whole structure to any requisite or answerable height.
G Flow-pipes from boiler.
H Return ditto.
I Openings at opposite end of flow-floor, for water to pass down through, falling into bottom floor, or return-pipes at J.
K The Boiler.
L The furnace-door, &c.
M End view of the structure.

The above is a plan of a pit-tank, &c., conceived according to my ideas above described; but instead of having a bottom-tank or floor for the return of water to the boiler, it may be found in some cases advisable to conduct it in its return, in pipes—either immediately underneath the flow-floor, or at the front of the house, pit, or whatever kind of structure it may be, erected upon the above principle; under all circumstances, I should recommend the upper flow-floor to be constructed the whole width of pit, taking care to provide a sufficiency of flow-pipes to equalize the flow in a continual and regular manner.—*James Barnes, Bicton Gardens.*

Home Correspondence.

Pruning of Forest-trees.—By the *Chronicle* of the 19th ult., I perceive that the dispute between the pruners and the non-pruners has been recommenced, and does not seem to promise a speedy conclusion. Dr. Thackeray and his men are strong in the flourishing condition of their plantations, while Mr. Billington and "Quercus" are by no means disposed to admit the success of Dr. T.'s system. The parties even differ as to the principles of the food and growth of trees, as well as to the best mode of depriving them of their branches. Now it appears to me that, as far at least as theory goes, these matters may very easily be decided. The principles of vegetable physiology, relating to the growth of trees, are now sufficiently ascertained, and are shortly as follow:—The roots absorb sap from the earth; the sap ascends the stem, pervades the branches, is elaborated in the leaves, and descends towards the ground, depositing a layer of new wood along with the peculiar products of the tree. There is no doubt also but that a considerable portion of the carbon required to form the woody fibre is derived from the atmosphere. Reasoning from these principles, we must arrive at the conclusion that the more leaves a tree possesses (and consequently the more branches), the greater will be the quantity of sap elaborated, and the larger the fresh layer of wood. Therefore, to prune to any extent, is just to impede in a corresponding proportion the growth of the tree. As to the method in which pruning should be performed, if we amputate at once a branch of any size, we diminish in a certain degree the increase of the tree during the next two or three years; but if we cautiously foreshorten the same branch one season, and two or three after, cut out the remainder, we give the tree time to recover the loss, by the formation of new branches, and so render its growth more equal. If we adopt the theory (which I am disposed to believe), of the expansion of the leaves in spring being the cause and not the effect of the ascent of the sap, these inferences will be more evident. Theory, then, is in favour of the non-pruning system, and nature corroborates the advantages of it, by the immense stems which single trees often display, compared with their brethren of the plantations. But nature must sometimes be assisted by art, and in order to produce length of stem, and freedom from knots and inequalities (properties that are in daily requisition), we are forced to prune to a certain extent. "Quercus" asks, "What is judicious pruning?" And I think with him that this expression requires to be more correctly defined than hitherto. It were much to be wished that some practical man, who has pruned on scientific principles, would make known his experience on the subject. It certainly appears to me that neither Dr. Thackeray's principles nor his practice are the true ones.—*Dendrophilus.*——"L. L." says:—"I have planted largely for many years, and latterly, from practice and experience, with good success. 'As doctors differ,' I hardly think I shall ever feel disposed to try the experiment of cutting off an arm or leg, when weakness and infirmities come upon me, to make my body stronger. The theory is new to me, and somewhat startling. In pruning, one's predecessor may have neglected his woods, and forced upon those coming after him to use the saw and hatchet, to put them into goodly shape and order; but I uphold that they are great enemies to foresters generally, even in men's hands who consider themselves great tree doctors. In infancy, plantations should have your best consideration, and if for six or seven years you will 'teach the young idea how to shoot,' by pruning them, and keep them clean, all that is required afterwards, or nearly so, would be to cut down and give room for those trees most valuable in shape, kind, and quality (saving thereby labour and expense), to remain, and as they continue filling up again the ground, renew the attack from time to time, as the growth of the trees demand. It is, I fancy, a by-gone idea that there is great profit in planting, and the idea quite obsolete that planting your best land is more profitable, in the long-run, than sowing it with grain. Where land is not easily cultivated, poor lime-stony land, the slopes of mountains, and, indeed, the summits of them, sandy plains, and steep declivities, I would say, might and do pay; at any rate, they would improve the bordering property, warm, and adorn it. I have seen lands planted on a large scale, too poor for culture and too bleak for turning into tillage, where trees have sprung up, and been cut down after 30 to 35 years' growth, except broad belts round twenty-acre fields; and those fields, from so many years' fall of the leaf, have borne the sweetest Grasses, and become very valuable sheep-paddocks. In such districts there is a strong incentive to plant, where you have an heir to reap the benefit of your outlay. Oaks will grow almost in any soil, by planting with them those good nurses, the Scotch Fir, Larch, and Alder. Give these air, sun, shelter, and attention when they are quite young, and clip their tender shoots with your fingers, rather than hack and hatchet them when the branches become strong, is the advice of one who Pontey'd in early life, but did not find it to answer."

Judicious Pruning of Forest-Trees.—"Quercus" asks, "What is judicious pruning, and how long is it to be continued?" Judicious pruning is every body's system who prunes at all—at least in their own opinion. Hence it is not easy to define it. The preventive system of pruning is that which I practise, and which comes near to "Quercus's" notion of "no pruning;" but the practice requires to be followed up occasionally on some kinds of trees, from a very young state until they are from 15 to upwards of 20 feet in height. The fine Larch in Mr. Gore's plantation, and the finest of others mentioned in a former communication, have had no scientific or judicious pruning by man. Mr. Gore's Larch had been surrounded by other trees, but not too near, which kept its branches within a moderate compass, and of a moderate size—just what the preventive system would effect. The same principle holds good with all other trees, when length, quality, and bulk of stem is required; consequently, very little pruning (lopping) will be required, if trees are properly trained on that system from a young state.—*W. Billington.*

Wilmot's Black Hamburgh Grape.—In looking over the report of the articles exhibited at a late meeting of the Horticultural Society, I observe that particular notice is taken of a Grape named "Wilmot's New Black Hamburgh." The berries are described as being "more fleshy, much larger than those of the old Black Hamburgh, and remarkable for having the surface covered with small indentations, as if they had been beaten with a hammer; the bunches beautifully covered with bloom." On referring to "Speechley's Treatise on the Vine," I find a Grape named simply, a Black Grape from Tripoli. Now, as this had been then only recently received direct from that part when Speechley was writing his Treatise, he had only fruited it very imperfectly in a pot; but Mr. Thompson afterwards had it planted into the diffused borders of the vineries, and the plants are now, as they were then, labelled "Black Tripoli," as is likewise the case at Worksop Manor. Now, the description of Wilmot's New Black Hamburgh so exactly agrees with the Welbeck Tripoli Grape, that I am much inclined to imagine it is one and the same Grape, which, from the indented surface of the berries, is usually distinguished by the name of dimpling. When the sun shines upon them they are readily seen to be very different from the Old Black Hamburgh, to which in general appearance the bunches have considerable resemblance, and in most places pass as such. This is a misfortune, as it is a much superior Grape, and often at Exhibitions takes the Hamburgh prizes, under the mistaken name of the Old Black Hamburgh. The Black Tripoli is a very different Grape from the Welbeck one, which may be said to be the very first on the list of black Grapes; and if judiciously treated has always fine black berries. It is as free a bearer as the the Old Black Hamburgh, and continues much longer in perfection than that variety, on account of its being less tender in the skin, more fleshy and solid, and also more saccharine. The berries grow as close together on the bunches as do those of the Old Black Hamburgh, and the bunches therefore require to be timely and well thinned.—*J. Mearns.*

The Golden Pippin Apple.—In the *Chronicle* (p. 622) it is said, "That celebrated physiologist (Mr. Knight) considered the Golden Pippin Apple to be in the last stage of decay. This doctrine of the deterioration and degeneracy of some of our best old Apples is unquestionably opposed to analogy in trees generally." The late Mr. Loudon was also of this opinion. About a century back, a large portion of the Herefordshire and Shropshire orchards consisted of the Golden Pippin and other celebrated old fruits, most of which have long perished by age and disease. We are now as fond of good fruits and fine cider as our forefathers, and repeated attempts have not been wanting by planters to substitute these old fruits as orchard trees again, but all have hitherto proved unsuccessful. Upon a border of rich dry sand, against a low wall, I have now dwarf plants of these sorts in a good bearing state; and as yet they are perfectly free from canker. But this will not last. It is only the old man whose life is a little lengthened by being set at ease from toil and exposure in the chimney-corner. Rather than lose time and excite vain expectations in mooting so settled a point, it is much better to follow the track of the celebrated physiologist, in proving, as he has done, that the best old fruits, if not to be exactly re-organised, may be substituted by a milar, or better, for ages to come. —*Quatfordensis.*

Rhododendron campanulatum.—Among the many ornamental shrubs that now decorate our pleasure-grounds, none are more deserving a place than this beautiful species, whose compact habit, fine dark sea-green, and curious rusty foliage, contrasting with the magnificent white blossoms, never fail to attract the eye, and stamp it as one of the best hardy evergreens we have. Seeds were first sent to this country by Dr. Wallich, from Gosaingathan, a mountainous region to the north of the valley of Nepal. Many plants have been got by grafting, but they are found not to answer so well as from seed or layers.—*Horacum.*

Shanking of Grapes.—Much has been said at different times in the *Chronicle*, on the shanking of Grapes, which the highest authorities have pronounced to be occasioned by the improper formation of the border in which the Vines are planted. Now, in the absence of facts, such authority, even when founded in theory, would be considered almost conclusive. I have it in my power, however, to relate a fact, which proves beyond all doubt that it does at least proceed from other causes also. About 20 years ago I prepared a border with the greatest care, the plan of which was submitted to and approved of by the late venerable President of the Horticultural Society. The Vines grew the first year with extraordinary vigour; and in the second produced a considerable quantity of fruit, much of which "shanked off," as gardeners oddly term it, and this has been the case more or less ever since, although the mode of treatment has undergone various changes. About 12 years after planting, being desirous of introducing bones and other materials into the border (which averages about two feet in depth, upon a close pavement of brick, placed upon a stratum of lime-rubbish, over one of gravel, upon a perfectly dry natural bottom of blue schistus), I had it turned over, and was much surprised to find almost all the roots near the surface. Most of them were replaced in a similar situation, and the remainder a little lower. Now, if we consider that in the first instance it was highly improbable (if indeed possible), that the roots could have penetrated into anything ungenial, and that subsequently, nearly all the roots were found near the surface, it appears almost certain that the cause usually assigned could not operate here, and must be sought for elsewhere. From long and tolerably close observation I am inclined to suppose that it might be occasioned by moisture collecting on the stalks of the Grapes during night, and the rays of the sun falling suddenly upon them, in a heated and confined atmosphere, before such moisture was sufficiently dissipated. If so, the present system of hot-water gutters may prove very prejudicial, which I have some reason to fear is the case, from the more than ordinary quantity of shanked Grapes in two divisions of my vinery this year, heated by tank gutters; whereas, in an adjoining division warmed by other means, there was no perceptible difference. Where the gutters were used, I also observed that many of the largest Vine-leaves damped off and fell, having rotted near the base of the foot-stalks. I hope that the attention of practical readers will be drawn to these points, as it may assist in clearing up the mystery that hangs over this subject.—*An Amateur.*

Thrips, &c.—The following paper, On a Simple and Effective Mode of Killing the Red Spider, Green Fly, Thrip, and Scale, without injury to Plants, was read at a meeting of the Horticultural Society of London, 2d August, 1837:—"Put the pots or plants into a frame well closed, and then Laurel-leaves bruised between them, when in the course of an hour the whole of the spiders and flies will be destroyed by the odour, which is that of Prussic acid; the thrip and scale will be destroyed in about eight hours—the night time being the most favourable for the experiment. For a house of 20 feet by 12, two bushels of leaves would be amply sufficient." I have not tried this mode of destroying these insects, but should like much to know if it has been proved to be successful in every case, it being a very superior method of extirpating such pests.—*Delta.*

Destruction of Green-fly.—I wish some of our chemists who are fond of floriculture would give their attention to the destruction of these pests of our greenhouses and frames. What we want is something as effectual as tobacco-smoke, cheaper, and of more easy application. I would suggest they should endeavour to supply us with some preparation in the form of pastiles, combining the above essentials. The demand would be very great. If nothing can be found to take the place of tobacco, a preparation of it in the above form would be very useful, enabling amateurs and ladies to keep this troublesome insect under. It should be remembered by such as may incline to give attention to the subject, that in filling a house with tobacco-smoke, it is necessary to keep some damp hay upon the top of the tobacco, to prevent the heat of the smoke scorching the plants, and to be most effective, it should be produced very rapidly. An ample reward would attend success, but nothing should be offered to the public that has not the recommendations above named, viz., destruction of the insect, simplicity of application, and both combined with economy.—*E. N. Beck.*

Marc de Colza.—I observe in a late Paper, speaking of manure for Tulips, that Colza is explained to be a kind of Rape grown about Caen; and it is asked whether oil-cake will do as well as Marc de Colza. The fact is, that Marc de Colza is oil-cake; Colza being the common name for the Rape-seed so much cultivated for oil in the north of France and Belgium.—*G. O.*

Peas.—As the time for planting Peas is fast approaching, it may be of service to know that the first plants may be preserved from mice by simply saturating them in a strong solution of Bitter Aloes.—*Early Charlton.*

Societies.

HORTICULTURAL SOCIETY.

Nov. 5.—The Rev. J. Antrobus in the chair.—In consequence of the darkness of the day, this meeting was held by gas-light. Among plants, perhaps the most remarkable object exhibited to the meeting, on this occasion, was a beautiful cut specimen of Renanthera coccinea, from Mr. Webster, gr. to Mrs. Huskisson. This Chinese plant, which is one of the oldest of its class imported by the Horticultural Society, is common near Canton, where it delights to scramble over old walls, on which its large spikes of rich scarlet flowers have a very imposing effect. Although Mr. Webster stated that this was the sixth season in which this plant had bloomed successively with him, yet it does not flower in this country with any certainty: and it seems by accident that the desired effect is produced. This is the more to be regretted, for the flowers continuing open for a considerable length of time, are very useful for drawing-room decoration. A Banksian Medal was awarded for it.—Of other Orchidaceous plants F. G. Cox, Esq., sent Lælia Perrinii, a beautiful species, and the rare Cattleya pumila, which is the least handsome of that genus.—From Mr. Robertson, gr. to Mrs. Lawrence, were good plants of Galeandra Baueri, Mormodes citrina, a finely-grown specimen of Epidendrum nutans, covered with large clusters of green-coloured blossoms; the old Cypripedium venustum, Lælia Perrinii, Saccolabium denticulatum, and Stanhopea venusta, the latter producing a fine spike of yellow blossoms.—From the same collection were also Erica Banksiana purpurea, and Lamberti roses, the latter covered with small flesh-coloured

blossoms; and a cut specimen of Aloe (? Aloe purpurascens, Haworth), a fine autumn-flowering species from the north of India, with showy purple flowers. A Knightian Medal was awarded for this Aloe, named plants.—From Mr. Parkinson, E. Barnes, Esq., was Pleroma [illegible] plant, with beautiful deep purple flowers; and a specimen of Gompholobium Lambertianum, which was awarded the Flora Medal.—From Mr. Dickson, gr. to Colonel Challis, of Gamlingay, came Leptospermum [illegible] which nearly related to Leptospermum lanigerum, was about 12 feet high, and clothed with a multitude of small white flowers.—From Mr. Bland, gr. to Mrs. Lee, of Hornsey, came a Certificate was awarded to a specimen of Erica [illegible] with a profusion of small pale flowers.—From Mr. Bland, gr. to H. Johnstone, Esq., was a Certificate was awarded to a specimen of Erica [illegible] which was very large, and covered with flowers.—From Mr. Bland, gr. to H. H. Oddie

...chaired by S. Jackson, Esq., J. E. Mills, Esq., J. Foster, Esq., E. Johnston, Esq., and the Messrs. Bryson, Lovell, Smith, and Jackson, members of the committee of management, and a large number of the nobility and gentry of the neighbourhood. The object of the meeting was to take measures for the establishment of a Society, whose chief aim should be to encourage the cultivation of the garden and the orchard, and to assist the industrious in obtaining the use of the necessary ground. The chairman, in opening the business of the meeting, stated that the committee had been induced to call it together, from the conviction that the establishment of a Society, such as that proposed, would be productive of much good to the neighbourhood. He was sure that the cultivation of the garden and the orchard would be productive of much benefit to the labouring classes, and would tend to wean them from the alehouse, and to make them more comfortable and happy at their own homes. He was sure that the cultivation of the garden

than by plunging them in a moist border, it is impossible to keep them in such a manner as to support some kind of a mat or canvas covering that will keep off the heavy rains. For if they are exposed to it, will wash the greater part of the nourishment out of the soil; and if they are kept quite dry amidst rain, I always find a great many broken by the time the Strawberry plants do best when treated in the manner described at page 703, the fruit obviously being that the soil is neither washed by rains, injured by worms, nor to some constant and heavy nourishment, the excess of the pre to the great injury of the roots, may be, in top fruit, as it is, after having been exposed to the rains of the early part of the winter.—*G.*

V.—HARDY FRUIT AND KITCHEN-GARDEN.

Fruit-room.—The present changeable weather will furnish an opportunity of examining and removing all decaying fruit. Those slightly affected should be taken out of the fruit-room and reserved for present kitchen use, as otherwise the atmosphere of the room would become vitiated, and to thicken the decomposition of all the stock. Most gardeners are fearful growers of the importance of a close atmosphere and an equable, rather low temperature for the long preservation of Apples and Pears. Warm, therefore, the fruit-room must not be used as a general receptacle, and whatever means will be will frequently be admitted, the fruit may be covered with clean Wheat-straw, which will help a little to keep it in a uniform temperature, and prevent its shrivelling by too much This is more necessary in the case not to this season as many of our best fruit are for table much earlier than usual. The best keeping Apples and Pears may be packed in jars or new garden-pots, covering each layer with dry sand; fine sand, such as is used for propagating, is much the better. Charcoal is scarcely ever be used for such a purpose, as however well dried, the moisture from the fruit is apt to make it ferment so as to vitiate the flavour. *Chestnuts, Walnuts,* and *Filberts,* are cleaner in the shells, and fresher and mealier in the kernels, when packed in sand than by any other method I have tried. Chestnuts, if previously well dried in the sun, may be kept in a room covered with straw, provided they be turned frequently; but the kernel is more shrivelled, and the inner pellicle is more adherent to it that when the fruit is packed in sand. The boxes or pipes in which it is packed, in sand should not be over large. If kept on shelves, or in heaps, unless in a very dry place, the outside shell, upon contracting a mouldiness, which will soon find its way to the inside if not removed. A quick method of effecting this, is to put a quantity in a clean sack, and move them backwards and forwards quickly by two men, each holding the two corners of the ends of the bag.

Root-house.—Remove all decaying and damaged Carrots, &c. Prepare suitable places for a supply of Parsnips, Celery, &c. being stored up on the dry approach of severe weather. Potatoes if kept in a house, and especially if raised in rather a wet state, should have dried Turnips, &c. placing through the heaps. When sufficiently dried, the draught of air may be stopped or regulated at will. When the flavour of newly-raised Potatoes is preferred to having them like a ball of flour, a quantity of earth neither dry nor wet may be sprinkled amongst them. With a little attention to ventilation, these roots may be kept as well in a house as by any other method, and any labour they require in spring and summer, can be performed in unfavourable weather. When one sees the large heaps of Potatoes piled in the fields together, and thinks of the heating and fermentation to which it is most surprising that their flavour should be deteriorated, and that when such tubers are planted, after an exhausting kind of vital energies, they either shrink into growth as if on a sickly vegetation.—*Ed.*

VI.—BROOMSTHORPE.

Old Woods.—Attend to directions given in late Calendars.

Conifers.—No time for delay in planting in dry, or in planting new ones, if possible. Remove the common Bird-cherry, or Hackberry, as grand objects, and thrown on account of its quick growth above Yours, it is useful for the same purposes as the Hazel, and thrives luxuriantly in moist ground.

Young plantations.—Go over with a view to the addition any planting that has been omitted in the former spring. As hares and rabbits begin their depredations upon young plants and trees, long before severe weather sets in, the sooner they are protected from them the better. A few days may cause much injury. I know of nothing of more easy application, or less unsightly, than a quantity of fresh night soil, (cleaning), now dung, soot, or ashes, this applied to the stems, in the form of thick plaster, will keep them perfectly secure from injury.

Hedge-row.—Should the work recommended to be done in previous Calendars, The Warentree and English Elms, with the Poplar and the Walnut, are trees suitable for hedge-rows in some localities.

Nursery Work.—Same as in late Calendars.

VII.—COTTAGE GARDENING.

Such of the cottagers as have a favourable situation against the wall of the cottage, or elsewhere—a south aspect, or one inclining to south, being preferred—have the choice of having a Peach, Nectarine, or Apricot tree, such as the Royal George, or the Noblesse (or Systonian), the Elruge, or the Violette Hative; and of Apricots, the Moorpark for dessert, and the Breda for preserving. Apricots bear well in some situations planted against the cottage wall, and in favourable seasons some cottagers make a handsome show of Peaches and Nectarines, where the trees have a good border, and are well attended to. In forming a border, clear out the soil to the depth of about 18 inches in the wall, giving the bottom a gentle slope towards the front, which there should be a drain, for the purpose of speedily carrying off all superfluous water. Cover the bottom of the border with concrete, or anything that will prevent the roots from getting down into bad soil, and then fill up with fresh turfy loam from the surface of an old pasture, if that can be procured. Where it cannot be avoided, as frequently the case, the border may be all paved over, with the exception of a small space round the neck of the tree, and used as a walk. In some of the best gardens, Apricots may be seen growing in borders made in this manner; and I have seen them on cottage walls, with the roots going under the pavement, bearing abundance of good fruit, even in spite of bad management as regards pruning, &c. Let all rubbish round the trees be cleared away to the manure heap, which should be occasionally turned, and covered in with soil. Everything that can be used as manure for manure should be collected for, as I have before stated, upon its accumulation the crops for next year greatly depend. Rough-dig any vacant ground, exposing it in large ridges to the action of the weather, as possible. Close your cottage, and put everything in order for the winter's blast.

State of the Weather near London for the week ending Nov. 4, 1843, observed at the Horticultural Gardens, Chiswick.

Notices to Correspondents.

Books.—*J.*—The Cacti are described in Pfeiffer's "Monographia Cactearum;" the Aloes, in the 4th volume of Haworth's "Enumeratio Plantarum."—*A Constant Reader.*—Apply to Mrs. Loudon, from whom the Numbers you want may be had.

CHINESE QUINCE.—*Dodman.*—This has been fruited in this country, but it requires a wall. The fruit is very different from that of either the Common or Portugal Quinces; it is cylindrical, about 6 inches in length, and exceedingly gritty. We are not aware of any attempts having been made to hybridise the Quince and Pear.

CHATSWORTH.—*J. M.*—There is no doubt about the weight of the masses of rockwork used at Chatsworth; they are of sandstone, and were removed in a very simple way, viz. by lamination.

CHRYSANTHEMUMS.—*C. P.* says, that all his Chrysanthemums in the *second* year always come pink. He had new varieties again last year, some of which were yellow, some white, and some pink, and they are all this year come pink, as they did before; the soil, which was made new this last spring for them, is composed of leaf mould two years old, rotten stable manure, and some rather clayish soil. We can offer no explanation of this supposed fact; but should fear that a change has been made among the plants themselves, rather than their blossoms.

ENDIVE.—*Dodman.*—The variety you have seen in Belgium is most probably the Corne de Cerf.

FRUIT-TREES FOR ESPALIERS.—*C. B.*—Apples: Golden Reinette, Blenheim Pippin, Claygate Pearmain, Ribston Pippin, Old Nonpareil, Herefordshire Pearmain, Court of Wick, Dutch Mignonne, Court Pendu-plat, Scarlet Nonpareil. Pears: Beurré Rose, Marie Louise, Glout Morceau, Bacon's Incomparable, Passe Colmar, Easter Beurré, Beurré Rance, Thompson's, Winter Nelis, Suffolk Thorn, Knight's Monarch.

FUCHSIAS.—*A. X.*—Cutting down the Fuchsia Corymbiflora will make it as bushy as its nature will permit, and not prevent its flowering next year; but it should never be grown as a bush. It ought always to be trained with a stem 7 or 8 feet high, and an umbrella head.

GESNERA ZEBRINA.—*A Subscriber.*—It is probable that some insects have eaten the round holes in the leaves of your plant, although you cannot detect them. It should be potted in rough heath-mould, mixed with about one fourth of silver sand. The pot in which it is grown should be well drained. It is a stove plant, and requires a humid atmosphere.—*A Constant Reader.*—Your (Gloxinia) Gesneria zebrina evidently requires more heat. The temperature should never be below 60° at night when the plant is coming into bloom. This plant will succeed best where bottom heat can be applied.

GRAPES.—*J. B.*—The Black Lombardy is the same as West's St. Peter's (not Oldaker's); bunches rather large, but not long; berries, large, roundish, black, thin-skinned, rich and moderate bearer.

HEATING.—*X. Y. Z.*—We quite agree with you as to the trouble, dirt, and inconvenience of growing Melons and Cucumbers with dung. Your plan of heating a series of pits with hot water seems so good that we will publish it as soon as a cut can be made. A paper on Tank-heating appears in another column, which you will do well to consult.

INSECTS.—*X. X.*—Should you have any opportunity of detecting the insect which bores into your standard Roses, and will forward specimens to Mr. Curtis, he will give you the information required. *R.*—*S. T.*—Your Oak-leaves are covered with the Oak spangle, which is produced by a minute Cynips. You will find their history in the *Gardeners' Chronicle*, vol. iii. p. 805. *R.*—*J. S—h.*—Your Vine-leaf insects are the larvæ of a Thrips. *R.*—*Nux.*—We must refer you to vol. ii. p. 108, for the history of the Filbert Beetle, which will enable you to judge what is best to be done. Burning the leaves and rubbish under the trees, and forking in lime, would perhaps be useful. *R.*—*P.*—We can only recommend you to persevere with the washing, for one infested plant may inoculate all the others in time. We think the gummy exudation cannot arise from the insects, as you say the Lemon-plant is now free from the Coccus. *R.*

IPOMŒA HORSFALLIÆ.—*Devoniensis.*—Cut your plant well back, and wash it with soap-suds and sulphur. It would be advisable to let it remain dormant until spring, then by syringing it morning and evening, when it begins to grow, the red-spider may be kept in check.

LASCHENAULTIA FORMOSA.—*A Subscriber.*—This plant should be grown in a warm greenhouse. Such soil as Heaths are generally grown in is suitable for it.

MILDEW.—*Dendron.*—Doubtless it is cold and damp together that have mildewed your Hendrobium nobile. At this Dendrobium like warmth, and 54° is too low for them. The total obstruction of sunlight has increased the mischief.

NAMES OF PLANTS.—*R. T.*—1, Hawthorn-leaved; 2, Golden-blotched; 3, *Veronica Buxifolia*; 4, Berry-bearing Sedum; 5, Adam's Fennel; 7, New Golden Pippin; 8, Dutch Mignonne; 9, Scarlet Crofton; 10, Cornish Gillyflower; 11, Prince's Russet; 1, Colmar; 2, False Colmar; 3, Glout Morceau; 4, Winter Nelis; 5, Beurré Rance; 6, Soulding Pippin; 7, Downton Gem; 8, Colmar; 9, Glout Morceau; 10, Beurré Rance; 11, Beurré Bosc; 12, Beurré Diel; 13, Passe Colmar; 14, Beurré Bosc; 15, Beurré Diel; 16, Passe Colmar; 17, Beurré Rance; 18, Beurré Bosc; 19, Beurré Diel; 20, Passe Colmar; 21, Beurré Rance; 22, Beurré Bosc; 23, Beurré Diel; 24, Passe Colmar; 25, Beurré Rance;

AGRICULTURAL COLLEGE.—At a Meeting of the Committee of Management, held this day, it was resolved:—That the Head Master be invited to apply for admission to Mr. Pusey's Agricultural Lectures, and that he must have a knowledge of Agriculture sufficient to be connected therewith.—The salary to be Fifty Pounds per annum additional, for every pupil above the number of 40. The master to be allowed the board in College for himself and wife, and a furnished dwelling in the College. A married man will be preferred.—Applications to be addressed to the Committee, at whose office copies of the Rules and Regulations may be had. Candidates will be required to attend the Committee, if desired, on the 20th of November, when the appointment will be made.—The Committee propose to give the superintendence and control of the whole establishment, subject to the Committee alone, to the person they may select to take part in the Farming, Teaching, or other duties, as circumstances may require.—Applications and Testimonials to be sent to Mr. Pusey, Pusey, Faringdon, Berks, on or before the 1st of Nov. 1844.

NOW READY FOR DELIVERY.

JOHNSON AND CLARK'S FARMER'S ALMANAC FOR 1845, containing Calendar, Tables, Statistics, and 160 Engravings of the best Agricultural Implements, with their prices and makers' names, &c. &c. Price only 1s. 6d.

JOHNSON'S TRACTS ON Agricultural Science, Geology, Farming, Manuring, Varieties, Calendar, and Agricultural Chemistry, each 2d.

2. A New and Enlarged Edition of JOHNSON ON MANURES; price 1s. 6d.

3. TEN TRIAL PAPERS OF AGRICULTURE. Translated by W. Shirreff, Esq., F.R.S.; and W. Blair, Esq., in a vol., price 2s. 6d. cloth.

4. JOHNSON ON SOILS. A New edition, enlarged, price 1s.

5. SQUARE'S AGRICULTURAL CHEMISTRY, for the Practical Farmer; 2s. 6d. cloth.

6. SINCLAIR ON GRASSES AND WEEDS OF AGRICULTURE; a Series of Plates, 30s.

Fleet Railway, Piccadilly, and every Country Bookseller.

The Agricultural Gazette.

Dec. 15—Green Ferry.

We continue our remarks on the practice of CHALKING LAND. In parts of Hertfordshire a heavy dressing of chalk raised upon the spot by means of shafts sunk through the soil, is spread at intervals of 14 or 20 years over the argillaceous portions of the London clay, and over the sandy and gravelly soils, occasionally overlying the lower beds of that formation. The drift constitutes the surface soil over a considerable tract, which skirts the base of the chalk hills, and is laid down in some of our geological maps as chalk, in others, as a member of the London clay. Its depth varies greatly and rapidly, being seen in the same field less than 3 feet and more than 10. In brickfields near St. Alban's its depth varies between 6 feet and more than 20; and it is less than a quarter of a mile from these pits has cut through the drift to the depth of 30 or 40 feet, without exposing either chalk or any beds of the London clay.

Analyses of the chalk of different localities, and of the same locality at different depths, are among the data wanted to place the improvement of land by means of chalk upon a rational and scientific basis. The geologist recognises in the white chalk upper, middle, and lower beds, differing in the abundance in which flints and organic remains are present, differing in their mineralogical aspect, and, of course, in their chemical composition. The chalk of one locality Mr. Lonsdale found to be composed almost entirely of organic bodies—microscopic shells and fragments of corals. In that of Brighton nearly 1 per cent. phosphoric acid has been detected. Do any portions of the chalk of other districts contain more of that valuable substance? Do all contain as much? Different beds of chalk contain different proportions of alumina mixed with the calcareous matter which constitutes the greater part of their bulk. For the improvement of sand or gravel we should expect that chalk to be the most efficacious which contained the greatest proportion of argillaceous earth; while for the improvement of clayey soils, chalk possessing the opposite qualities would appear to be preferable. The farmers of Suffolk prefer the chalk brought from Kent to that which lies under their own fields. Does this arise from difference of composition, or from the cheaper rate at which the Kentish chalk can be procured, by reason of the large scale on which the pits are worked there, and the depth of soil lying over the chalk in that part of Suffolk where it is used? These are important questions, which can only be solved by a rigorous chemical analysis of the chalk of different localities. But who is to undertake this important though expensive work? It is a work in which, in our opinion, a portion of the funds of the Agricultural Associations might be profitably spent.

We have made arrangements for laying before our readers details of the practice of chalking land in those districts where it is most prevalent; and Mr. Gyde, of Painswick, has undertaken the chalking of a series of specimens of chalk from different portions of that formation, with which Mr. Trimmer will supply us. The results of these analyses will appear in our columns.

We shall conclude this week's article with a few practical details of the Hertfordshire mode of chalking obtained from some workmen whom we found engaged in the process. The field on which they were employed was a Wheat stubble, in course for a Turnip fallow; the adjoining field, a Clover ley, had just been chalked for Wheat. They were situated in the parish of Ridge, at the foot of the hill of the same name; the soil was a gravel, with a light loamy base, belonging to the drift formation. Its depth, as exhibited in one of the two pits which were open, was about three feet; in the other nearly ten.

The chalk was raised by means of a common windlass, in a bucket holding a bushel. Twenty-two of these are called a "yard," or a load. How many loads they were spreading to an acre the workmen did not know; some farmers, they said, laid on 100 loads; some less. From the thickness of the covering, we should consider full 100 loads to have been used in this case. After the work is finished, the excavation is filled up by throwing in the soil and chalk from round the mouth of the pit, thus producing a slight hollow in the field. There was in this case a contractor for the whole job, between the farmer and the workmen. The men stated the price received by them from the contractor to be 6d. per load of 22 bushels for raising the chalk, carrying it over the land, and spreading it. The cost of the operation, at this rate, supposing the largest quantity above-named to be used, would not exceed 50s. per acre, and the benefit of it would be felt more than 14 years. It was stated by one of the workmen that his grandfather had been accustomed to receive 1s. per load where they had 6d. At the latter price they said they could earn, by a hard day's work 10s. or 11s. a week. It is usual to sink pits at such distances that the chalk can be wheeled from them over the field; but in this case, the covering being deep on one side of the field, and the farmer being unwilling to disfigure the surface by more of the hollows which remain after filling in the pits than were absolutely necessary, allowed the use of a horse to draw the chalk to those parts which were beyond wheeling distance.

We have no doubt this account will draw forth further particulars from some of our readers resident in the district. The amount of alumina and phosphate of lime applied to this field in a dressing of 2200 bushels of chalk we hope to be able to announce before long.—*E. W.*

CULTIVATION OF WHEAT ON THE SAME LAND IN SUCCESSIVE YEARS.

In Oct., 1843, you published an account of an attempt of mine to grow Wheat on the same land year after year. As the subject appears to me to be an important one, and as many persons who may read this letter may either not have seen the former, or may have forgotten it, a short summary of the former experiments may not be out of place.

These experiments were commenced in the autumn of 1841, after the field had been cleared of a crop of Oats, which was a very bad one; the land being not only naturally poor, but foul, and exhausted by long cropping. As the season was very wet, it was indifferently cleaned, and *one-fourth* of it manured with a compost of night soil and ashes, and then the field was sowed with Wheat. Two of the remaining three-fourths were manured on the 6th of May, 1842 (the spring being a very dry one, no rain came until that day), one with guano, the other with nitrate of soda, each at the rate of 2 cwt. to the statute acre; and the remaining fourth was left unmanured. The following were the results at harvest:—

	Bushels (of 60 lbs.) per acre.
That manured with night soil and ashes produced	32
" " guano	27
" " nitrate of soda	27
Unmanured	19½

When the field had been cleared of the crop, it was immediately ploughed up; and, as the season was favourable, the land was well cleaned, and sowed with Wheat in October, 1842, without any manure, except Lawes's guano, which was scattered over it when the Wheat was coming up. The field was divided into three portions; and on April, 1843, was manured as follows:—No. 1, with 60 lbs. of sulphate of magnesia, and 2 cwt. nitrate of soda to the statute acre; No. 2, with a compound from a manufacturer of chemical manures, and No. 3, with 60 lbs. of silicate of soda, and 2 cwt. nitrate of soda to the acre; with the view of still further varying the experiments, by the addition of silica, combined with guano, for sight after the application of the chemical manures. The crop promised to be a very good one, but it was much plundered by the birds; and at this summer was taken a sufficient number of feet. Allowing for the deterioration occasioned by the birds, the crop per acre was estimated at [illegible] bushels (statute) [illegible] and in that part of No. 3 which was also covered with guano, it reached by actual weight (not by estimate) 38½ bushels of grain to the acre. These patches in Nos. 2 and 3, which had given out of them, suffered so much from the depredations of the birds, that no account was taken of them separately.

The crop was cleared off the land, which was cleaned, sowed, and ploughed in, last year, on the 3d October, 1843. It was drilled in rows, seven inches apart, and at the rate of 2½ bushels to the acre. It is to the results of this last year's cultivation that I now call your attention.

Before sowing, the land was sub-soiled to the depth of from 14 to 16 inches, except a strip of about 10 feet in width down the middle of the field, which was left unsubsoiled, for the purpose of ascertaining what were the advantages derived from subsoiling. The advantage was merely that of thorough draining (for the field had been previously drained previous to the subsoiling). It was thought possible, that this strip of 10 feet wide would be drained by the subsoiling on each side of it; but in addition to this, the Wheat plant derived more nourishment from the manure put into the soil, where that was loosened by the subsoil plough, the crop ought to be better in the subsoiled than in the unsubsoiled part. The field was over the ridges of a hill, and upon that account the soil is in good condition. It was deemed expedient to give it a slight dressing of coal ashes and night soil, from an idea that the plant would scarcely survive the winter unless some stimulus were applied there; but the ashes contained little manure, and were only applied so the worst part of the field, covering about one-third of its surface. The Wheat was Spalding's Prolific; it came up evenly and well all over the field. It was hand-sowed with lime early in February, to the extent of about 24 cwt. of dry lime on the acre.

In order to ascertain the value of lime, and the proper quantity, I had the field uniformly covered with it, except one land, which was left entirely without, and the headlands, which had one three, the other six times as much lime put upon them as any other part. The field was also dressed with chemical manure of the following ingredients, on the 26th March, viz.:—

[illegible] cwt. nitrate of soda
[illegible] cwt. impure silicate of magnesia
[illegible] cwt. silicate of soda
[illegible] cwt. common salt
[illegible] cwt. guano

Speculating on the probability of a dry summer, I gave it an extra quantity of manure and chalk: that where guano is used afterwards, it will by me the nitrate of soda might be dispensed with, which would bring the cost to 22s. 6d. per acre. I should prefer guano to nitrate of soda, because of the other matters contained in the former. At the distance we are from the sea (about 30 miles), it would seldom be necessary to apply common salt, as the gales of winter generally bring as much as is needed; but last winter we had no such visitor, I think though, that where salt was applied, along with the other chemical manures, the Wheat was more luxuriant than where there was none; but the point is not understanding of the [illegible] was not kept separate.

When the chemical manure was applied, one land was left without it, for the purpose of comparison. Guano was sowed on the land on the 29th March, at the rate of something less than 2 cwt. to the statute acre; one side of the field being covered with Peruvian, the other with African; and the land on which no chemical manure had been sowed was, half of it covered with guano, and the other half left without anything except lime; but as it was thought desirable to ascertain the value of the chemical manure without lime, each half of this patch was sowed with the chemical manure in April, after the long drought of the last spring had thoroughly set in. A small patch was left unmanured, in order to show the natural condition of the land, and to serve as a comparison both with the manured parts alongside of it, and also with the condition of the field when the experiment commenced, in 1841-2, when the [illegible] portion yielded only 19½ bushels per acre. This part of the experiment, however, was frustrated by the carelessness of the men who threshed out the crop.

The crop was a very good one throughout the field, but was evidently shorter and thinner where there was no lime, and also where guano was applied alone. It was best on the headlands, where more lime had been applied.

The weather was exceedingly favourable until the wheat was going out of bloom; but it then changed, and the crop was beaten down by the rain, in some places so thoroughly that it never rose again; and from that time to this day it was ripened (the 21st August) there were not more than six fine warm days. This cold and ungenial weather would, no doubt, materially affect both the quantity and the quality of the crop, the sample being only just fair.

On threshing out the crop, I find the result to be as follows:—Where the guano and chemical manure were applied, but no lime, the yield was 19½ bushels (of 60 lbs.) per statute acre; where the land was left unsubsoiled, it was 32½ bushels; where guano alone was applied, it was 32½ bushels; where the chemical manure alone was applied, it was 43½ bushels; where the African guano was applied, it was 45 bushels; where the Peruvian was applied, it was 52½ bushels; on the headlands, where three times the quantity of lime (or 3½ tons per acre) was applied, it was nearly 62 bushels; and where six times the quantity of lime (or 7 tons to the acre) it was 49½ bushels. I give this last result as it was ascertained, but do not consider it conclusive, for the

Wheat-plant on this manured looked quite as well as the other, until it went out of bloom, when from some unknown cause, it was entirely blighted, in irregular patch, from a foot to 2 yards in width, and extending almost from end to end of the manured row, becoming brown and parched, as if affected by lightning, or some atmospheric visitation. When the rest of the crop ripened, the results were clearly to the eye. I subjoin the following tabular statement of the produce per acre, in the different parts of the field:—

Guano alone	32 bushels.
Chemical manure alone	24
Guano and chemical manure, with views of [illegible] on the wheat-seed and middlings	[illegible]
Do. do. do. and [illegible]	[illegible]
African do. do. do.	43
Peruvian do. do. do.	[illegible]
Do. do. do. [illegible]	[illegible]
Do. do. do. [illegible]	[illegible]
Average crop thereupon the field	[illegible]

It may be as well to observe, that the total expense of the manure, and of its application, to that portion of the field which produced 32 bushels per acre (including the guano and the additional quantity of lime used), came to the rate of 31s. per statute acre. Deducting the cost of the nitrate of soda, the utility of which, under the circumstances, I am inclined to doubt, it would have been 23s. 6d.

I consider these to be very favourable results, and as offering strong inducements to continue the experiments. I have accordingly had the land ploughed up and cleaned, and it was again sown with wheat on the 9th instant.—*Farmer's Magazine.*

ON FLAX-SEED AS FOOD.

To many of the readers of the *Agricultural Gazette* an apology may be necessary for bringing this subject so frequently under their notice; this may not be impressed with a clear idea of its importance to the farmer. In a recent paper in one of the numerous agricultural publications of the day, while advocating the advantages of another addition to the list of cultivated plants in Britain, the writer appears to entertain such very extraordinary notions respecting the culture and the application of the seed to food for live stock, that the hopes he has aroused of the one and the fears he has awakened of the other are now so sensible of their folly, that they will little help either cause, and not unlikely the ultimate condemnation of their countryman, on whose behalf they have so shamefully imposed upon the credulity of the public. I refer to Mr. [illegible] paper, which, although [illegible] language is strong indeed, that [illegible] proceeds more from gross ignorance and [illegible] of the subject than from any wilful misrepresentation. It is, in fact, language [illegible] whose sole efforts are devoted to the [illegible] of their own class of their fellow-creatures, should be attached to [illegible].

[illegible] Flax culture in this [illegible] particularly anxious to [illegible] sanguine expectations [illegible] realized thereby to be obtained. I [illegible] was favourable or profitable [illegible] be adopted, and that such [illegible] requires a greater degree of [illegible] in the performance of the several processes connected with it than is necessary in the case of almost any of the other cultivated crops. On these grounds, then, it will [illegible] that such farmers as had not previously had opportunity of acquiring a practical knowledge of the mode of proceeding adopted in the Flax-growing districts, should be cautious in their first attempts to grow the article, and that their operations should, in the first instance, be conducted only on a small scale, until they were satisfied that they were likely to be successful. In regard to the use of Flax-seed as food, such precautions were scarcely necessary, as the quality of the substance used in a particular form by British farmers from a very early period has been very great. Oil-cake has always been in high and deserved repute as food for the domestic animals of the farm, and perhaps it was no great innovation of established practice to recommend the use of the genuine seed itself. Many farmers are aware of the extent to which adulteration has been practiced in the case of the portable manufactured cake, they are abundant grounds for stating that a similar system has prevailed in the case of oil-cake, which, being a valuable substance, held out greater inducements for the adoption of such a course. This imposition, however, can be guarded against by using the seed itself instead of the cake prepared from it, and in the former case it is quite [illegible] that no adulteration can take place which the most simple examination will not [illegible] In the [illegible] of the nutritious ingredients respectively contained in the Flax-seed itself and in the cake [illegible] usually existing [illegible] former is concerned with the [illegible] much in its favour. [illegible] difference in money between [illegible] important reasons also exist for a preference [illegible] to the seed, which need not here be [illegible] have been so recently [illegible] in former [illegible] on the subject.

The numerous inquiries [illegible] on the subject are, indeed, the best evidence of the system of feeding here recommended becoming more popular. That most misrepresentations [illegible] regarding it is evident from the nature [illegible] of the questions asked as to the manner [illegible] into effect. A Gloucestershire farmer [illegible] that he had made good thick jelly from Flax-seed [illegible] boiled into meal, but cannot [illegible] that its effects in fattening cattle are [illegible] to that of the common oil-cake, and assumes as a reason for the supposed inferiority of the former, that the seed may not have been sufficiently reduced before boiling, and that therefore a portion of the oil may have passed through the animals without its having been digested. The reduction [illegible] to a state of meal, and [illegible] the [illegible] of the oil, [illegible] the [illegible] of the [illegible] is no good reason assigned for the inferiority of the latter to the former, as it is [illegible] sufficient for ascertaining the [illegible] of the [illegible] of food. In the third [illegible] the [illegible] Flax-seed [illegible] with [illegible] of the [illegible] of the [illegible] with both theory and practice, as far as already applied, it is [illegible], it certainly requires little [illegible] to [illegible] that it [illegible] to [illegible] the subject of Flax-seed as food [illegible] those considered apart from the cultivation of Flax as a [illegible] crop. The chief supply, both of seed and cake, is at present obtained from the Continent, from which, no doubt, an increased quantity may be obtained, if required, so that it is altogether a matter of after-consideration how far it may be advisable to raise Flax-seed in Britain in preference to importing it from other countries. When the seed is consumed on the farm, it is certain that Flax is a highly *restorative*, and not an *exhausting* crop, as many have supposed; and from this circumstance, a gradual increase of the cultivation of that crop need not sensibly diminish the production of Wheat.

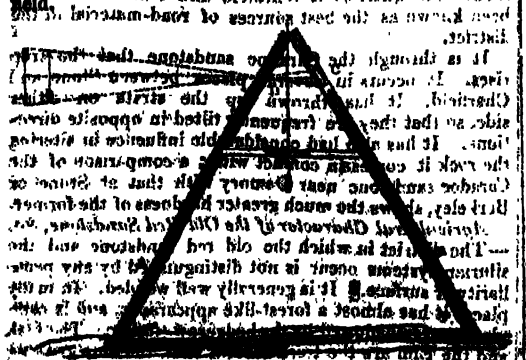
Experience having proved the great value of house-feeding in almost every case in which it is practicable, both as economising food and adding greatly to the stock of manure, advantage has been taken of the unexampled nutritious properties of Flax-seed to carry that system of feeding into effect, where it could not without this auxiliary be introduced; and instead of the usual method of confinement by stakes and chains, Mr. Warnes introduced the plan of feeding the cattle in boxes, somewhat similar to those in which sick horses, or brood mares with their foals are confined, as a medium between confinement by tying to the stake and more confinement in open yards, with shelter-sheds attached, as is usual in the practice of Scottish farming. This system, while it affords ample opportunity for moving about in the inclosure, secured a more uniform degree of warmth to the animals—a consideration of which modern science has abundantly shown the importance—and guarded the manure made by the animals from loss by exposure to the weather. This plan of box-feeding is, of course, applicable in the case of other articles of food as well as Flax-seed, and cannot therefore be regarded as a peculiarity consequent on the adoption of that article of food. Many inquiries have been made relative to the construction of these boxes by persons anxious to make a trial of Flax-seed, but it will be seen, that though a highly desirable arrangement for feeding cattle at all times, it is not necessary that the slightest change should be made in the arrangements of the farm-yard for that purpose. For the satisfaction of such inquirers, a description of Mr. Warnes's boxes is given; but it is hoped that these observations will tend to remove much misapprehension which at present exists on the subject, and remove one of the chief obstacles to the more general introduction of the system of feeding so strenuously and justly recommended by that gentleman. The description which follows is that of his own boxes, and given in his own words:—

"The description of these buildings is difficult, because however clear and explicit, it must convey ideas of magnitude and intricacy, while neither exist. To make ten boxes, a space will be required of 90 feet long and 12½ feet wide; then let a line be drawn from one end to the other 3½ feet wide, from the side most convenient to the passage. Next let the mould, to the depth of one foot, be excavated from the other part, and thrown on the side intended for the front, and spread to the thickness of a foot deep; this will give two feet from the bottom of the boxes to the surface. A wall of brick-work, 4 inches wide and 2 feet high, is next to be built round the inside of the part excavated, and intersected at distances of 8½ feet. At each angle, the brick-work should be about 12 inches square, which will both support the posts, and afford strength and durability; upon the wall a sill of wood is to be placed, for which purpose large poles, split or square, are adapted. The foundation being now complete, posts 6 feet long, and the necessary rails and ties, may be placed upon it, across the less the most ordinary poles may be laid to support a roof composed of the trimmings from hedges [illegible] inches, and completed with a thatch of straw or rushes. Two gates must be added to each box, one in front and [illegible] to open on hinges, and the other to be [illegible] to the [illegible] [illegible] of the [illegible] [illegible] [illegible] plan is pleasure. Presuming that [illegible] [illegible] [illegible]

The land of this track is generally too narrow, that those portions of the farmer's experience which would induce him to alter in any case the general practice of the district around him.

The general rotation in the fourfield course which I have already quitted is—1st, Fallow; 2d, Wheat; 3d, Barley; 4th, Seeds; 5th, Potatoes. The two latter crops is here sometimes substituted by Turnips, but almost omitted altogether. Lime is universally applied on the fallow once in three years. This frequently done before the Wheat crop. Lime is sold on the land at the rate of 60 or 80 bushels per acre. The average of the crops per acre are—Wheat 20 bushels; Barley, 30 bushels; and Potatoes less than 7 tons. This soil is not really fitted for the growth of Turnips, but few Turnips are grown. The soil on the old red conglomerate and its associate beds is rather of a light nature, but is certainly capable of producing, owing to its disintegration, a fine loam and to all appearance

The land on the lower members of the old red is much covered with extensive timber, chiefly Oak. It is generally a healthy dry soil, partaking more of the nature of the clayey than of the sandstone strata of which its subsoil is composed. The best of it are in pasture. The crops are many and of every description—both of the yellow Dawwheat and the white Moon flower. Over the whole district the crop of hay will not average 1½ tun per acre; about two-thirds of it are mown each year, and on many farms this portion is not shifted about among the several fields, but certain fields are grown, and the rest of the farm depastured during a succession of years.



Between Berkeley and Parcell the land is much overrun by Elm and Oak in the hedgerows. A three-field course is here followed—Wheat, Beans, and Potatoes being the crops cultivated. The soil here is sometimes a stiff clay, and at others it is brashy and sandy. If it were drained, the greatest improvement would be effected. Nowhere else in the county would such marked effects follow the use of this invaluable means of agricultural improvement. Drainage not only improves the capabilities of the soil, but it greatly diminishes the expense of cultivation, which is not an insignificant item in the sum total of the advantages attendant upon it. The answer to the question—"Would you, if you were allowed, break up a larger portion of your pasture-land?" which I frequently put, was uniformly answered in the negative on the undrained clay soils of the district, and in the affirmative on all the sandy and comparatively dry soils—and few wholly on account of the great expense of cultivation wherever the soil is wet.

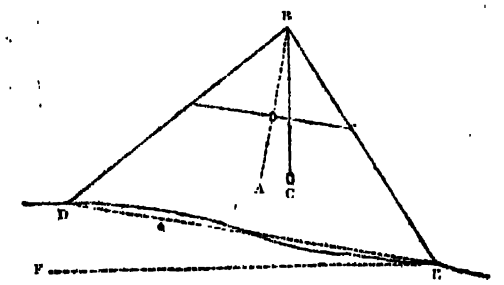
The average per acre, near Berkeley, of the Wheat crop is above 20 bushels. The Potato crop generally does not belong to the farmer. The land for the purpose is let to the labourers, and others the farmer first cultivating and manuring it. It is in this way let as high as 8l. per acre. The kind of Wheat sown is the old Red Lammas. On some of the pasture land, clay-draining has been followed to a considerable extent, and the mole-plough has also been used. The soil is at all enough to admit of these drains, and at the same time sufficiently free to drain easily, so that great success has followed them. They are, however, entirely confined for the arable land, each drain is being stopped by the treading of horses in wet weather.

Over the whole of the silurian formation the land is pasture, which is similar in quality to that on the old red sandstone. It is superior, however, to that on the poorer sands of that formation, but with it requires drainage, which is but rarely done. The crop-rock being of very small extent is not of much agricultural importance. It is covered by a red, apparently barren, soil, generally close upon the rock. It is shrubby, as pasture, and affords a Grass superior in quality to that on the formation surrounding it, and in wet seasons superior in quantity also. It is a deep soil, and would pay better to be cultivated as arable land than as pasture, being fertile, deep, and easy of cultivation. It possesses the three great requisites of good arable land.

MR. DENTON'S LEVEL.

Being daily in receipt of communications on the matter of my A Level, you will, I may judge from the number of these communications, interest many of your readers by affording me the opportunity of explaining the geometrical problem upon which this simple instrument is based, and the mode of using it in the field.

It is through the [illegible] that the observer will comprehend the science, the portability and the facility with which it may be used, of simple the surface or in the trench. The legs turn upon a hinge and fold into grooves cut in the [illegible] legs may be closed in a pair of seconds, folds and the whole may be tied into a small bundle for measurement. The legs are sufficiently narrow to stand in the narrowest trenches, while the cross-bar will afford the means of testing the instrument on the surface [illegible]



The object of the instrument is to assist foremen and workmen in setting and preserving a uniform fall in all works requiring such regularity. In spirit-level, although understood by workmen, is a thing easily put out of order, and to all but [illegible] liable to be broken into use, therefore is dreaded by workmen, as a process involving much [illegible] time, care, and precision, for which fingers are performed.

In draining and sewering, if the first object of the operator is to direct his drains according to the best fall of the ground, the next point of importance is that the flow of the trench, and the course of the tiles, soles, or bricks, should be even and regular from the top to the bottom of the drain. Any hollow in the drain intercepts the sedimentary matter which the flow of the drain water would otherwise carry out with it; the sectional area of the water-way is thereby lessened, and the sediment, gradually accumulating, after a time causes a stoppage, the drain bursts, and the work has to be re-done.

The level placed in the trench, as it is dug preparatory to laying in the tiles, indicates by the plumb-line any irregularity bad workmanship may occasion. Such use of the instrument is merely analogous to the mode by which the carpenter applies his square and plummet. It is my wish to prove that the extended principle upon which the A Level is based is so sound, that if accurately constructed, the instrument cannot work otherwise than with perfect efficiency, *in determining the average fall of surface between any two spots within sight of each other*.

It should be observed, that the legs of the instrument being equal in length, form, with the base upon which they are placed, an isosceles triangle, and that, when that base is perfectly level the plumb-bob pendent from the apex must necessarily divide the triangle directly in half. This admitted, it is equally clear that by means of a bar connecting the two legs at any given distance, and exhibiting on its face the centre or half of the angle at the apex, any person is competent, guided by the plumb-line, to raise or depress one leg until it stands on a level with the other: the plumb line will then hit the centre.

Now, as the plummet will always hang vertically, by reason of its weight, any rise or depression of either leg is immediately indicated on the connecting bar by the equivalent deviation of the plumb-line from the centre.

The angle A B C is equal to the angle D E F, *i. e.*, the angle made by the hypothenuse or surface with the horizontal line, is equal to the angle of the line dividing the triangle in half, with the vertical line.

Thus, the difference of height between D and E may be calculated by multiplying the natural sine of the angle D E F (read off on the bar as A B C, *if the index represents degrees*), by the length of the ground spanned between E and D. In the A Level, this is already done; and instead of degrees and minutes, inches and quarters are divided on the bar, so that the operator may at once read from it the difference of height between the two spots upon which the instrument stands, and *vice versâ*. If it is required to sink one leg an inch below the other, the ground is lowered until the plumb-line strikes the 1-inch division of the index on the bar.

It will be seen, that at a certain distance from the apex, on each leg a line of sight is shown. On the one leg there is a sliding sight-hole answering to a fixed index, agreeing with that on the bar B; on the other leg, there are cross hairs fixed, the centre of which are exactly the same distance from the apex as the centre of the index on the opposite leg. The line of sight therefore from these two points is ever parallel with the base of the instrument.

To arrive at the [illegible] fall or surface from the top to the bottom of a field, the instrument must be placed on a level by means of the plumb-line. The operator must then [illegible] to and fro drain, with a rod marked at which he levels to and fro drain, with a rod marked [illegible] a point where the line of sight cuts the ground, [illegible] between the [illegible] point. [illegible] reading with the height of the cross hairs B, above the base of the instrument. He then slides up or down the sight-hole until he fixes the cross hairs upon the paper in the stick.

This line of sight C B C, is parallel with the general line of surface E D, (regardless of its singularities), and therefore forms with horizontal line of sight A B A, an angle C B A, equal to the angle D E F, formed by the plumb-line central and the surface.

Now, as the opposite angles of lines crossing each other are equal, the angle A B C is equal to the angle C B A; and we have shown that the angle C B A is equal to the angle D E F; therefore A B C is equal to D E F, and consequently you are enabled to read from the index at C, the angle *converted into inches and quarters*, which is common to the whole distance from E to D. The height thus settled is transferred to the bar B, and retained by the sliding stud G (see the woodcut), to the edge of which the [illegible] is afterwards worked. This limb is used only to save memory, and assist the man who cannot read.

From the explanation I have given I have shown that, without any measurement of distance whatever, the average fall of surface is arrived at without any chance of error, if the span of the instrument is always the same, and the indices are accurately made agreeable with that space in the first instance.—*Dudley Beacon.*

THE ALLOTMENT SYSTEM IN IRELAND.

I am well pleased to find this system making its way in England, and am not surprised it should encounter some opposition. But that the objections of the farmers, as mentioned in the *Agricultural Gazette*, of the 12th October, are ill-founded, I think no better proof can be offered than the beneficial effects produced by the allotment system in Ireland, where with its modifications it has long been in operation. That it is highly advantageous to the labourer cannot admit of question; without it he could not exist in the dearth of employment, and with the low price of labour, in few places exceeding 8*d.* a day, that it is of much, indeed of essential service to the farmer is evident, for without it he could not pay his labourers; in his want of capital it is, in more than nine cases in ten, his only means of working his farm; it constitutes for him a species of credit, while it gives the labourer a security for his wages. The Irish labourer, whose day clothes are often his only night covering, whose bed is straw, and whose dwelling a hovel, is, by this allotment system, independent of the workhouse and of parish relief, and is virtually a capitalist, for he very generally has, through it, his year's provision in advance.

In many parts of Ireland, the main allotment system obtains, the labourer having more or less land which he holds with his house, and which, from his employer, the rent is paid by his labour, at a stipulated price—an arrangement of which he is very fond to avail himself, and in consideration of which he will give a higher rent for his allotment than he otherwise would. I have a gentleman farmer, in the neighbourhood of Portumna, where labourers' wages were only 5*d.* a day without meals; but they each held from him a house with an acre of land at 30*s.* a year, the grazing of a cow at 30*s.* more for the winter feeding of the cow at from 20*s.* to 30*s.*, a ton; so that these labourers lived in comfort, as the most people of their class, and at the end of the year their accounts were pretty equally balanced. In Tipperary, I found some holding a house and an acre of land for two guineas a year, the summer grazing of the cow at two guineas, and the wages at 7*d.* a day.

What I would call a modification of the allotment system is the potatoe conacre plan which appears to prevail in Connaught, and in the central districts of Ireland. Old Grass-land is let in small lots to the poor people for two or three crops of Potatoes in succession, followed by a couple of crops of Oats, at an annual rent of from 3*l.* to 6*l.* the [illegible] acre—that is, from 3*l.* 2*s.* 6*d.* to 5*l.* the statute acre, according to the goodness of the ground, and its capability of giving crops with or without manure, for the two or three years it is under Potatoes; and from 2*l.* to 3*l.* annual rent of the statute acre for the two years it is under Oats. Another plan more general in the south is the occupation of a hovel and a perch or two of land, at from 40*s.* to 40*s.* a year, and a portion of land ploughed and the manure placed on the ridges ready for trenching in of Potatoes, at from 5*l.* to 8*l.*, the statute acre according to the goodness of the land and manure, the labourer feeding the land and doing all the labour of it, and working out the rent at from 6*d.* to 8*d.* a day. In these cases the land is only let to them for the crop-season.

Now, as a good statute acre of Potatoes will be from 8 to 12 tons, and as they are worth from 1*l.* to 2*l.* a ton, and sometimes more, and very seldom so low as 1*l.*, we may take the average and it is rather a low one—at 1*l.* 10*s.* a ton, and taking the average of produce at 10 tons to the acre, we have 15*l.* for the value of each acre of Potatoes, and as the average rent may be taken at 5*l.* an acre, we find that the allotment system virtually doubles the wages of the labourer, without laying any additional charge on the farmer.

But the allotments of the poorer classes of Ireland are under the worst possible treatment, and as we may expect more and superior management in the allotments in England, so we may expect far more beneficial results. I have no hesitation in saying that an acre of ground, under proper treatment (and I will, at some future period, submit courses for an acre and smaller lots), will give an English peasant as much Potatoes and vegetables as he chooses to eat, a pig at Christmas, and the support of a small cow, such as our Kerry, with the exception of her keep for the year. Half an acre may give him his Potatoes, vegetables, and pig or pigs.

I assure the farmers of England that I never yet knew an Irishman rendered so independent of his employer as to become a saucy and bad servant from his possessing his bit of land; it is attended with a contrary effect, for his dread of losing it is such that he is made much more subservient, and more to be depended on, than the casual day labourer. He becomes, indeed, an interested person, and I have known him even submit to a blow from his employer, rather than leave his service and lose his land. I have resided in Ireland nearly 27 years, and may, therefore, speak with some confidence on this subject.—*J. M. Goodiffe, Granard.*

Home Correspondence.

Mildew on Barley.—It may, perhaps, interest some of your readers to learn that the little black specks, which are so common on the straw of the late Barley crops, are a form of the true mildew which is so destructive to Wheat. I have never observed Puccinia graminis on Barley before, and the heaps of spores are so small, and completely concealed beneath the cuticle, that their real nature would scarcely be suspected. The parasite is too imperfectly developed to be at all injurious. The grains, especially in shady parts of the field, are much infested with Cladosporium herbarum, which makes them nearly black, and there is scattered over the leaves and sheaths a minute club-shaped, jointed parasite, which gives them a speckled appearance. The crops themselves are very heavy, and have been for the most part secured, notwithstanding the unpropitious weather, in tolerable order, and it is thought will yield a fair sample: the heaviest crop was not sown till the 17th of June. Those portions only which were reaped have suffered from the wet, in consequence of the sheaves being more tightly bound, and therefore not admitting so free a current of air. The mould which your Buckinghamshire correspondent found on Wheat, and which proved to be a form of Erysiphe communis, has been, I believe, almost universal, but it does not appear, in any case that I have witnessed, to have been injurious to the produce, though so very abundant. With us, those portions of the leaves and sheaths were most affected that were covered with the red rust, a parasite which, though so much dreaded on the Continent, even more than mildew, as it should seem from Philippar's account, does not appear in Great Britain to do much harm, at least to the red Wheats.—*M. J. B.*

Gypsum and Guano.—In the *Agricultural Gazette* for Oct. 16, a correspondent is informed, that it is questionable if gypsum would tend to fix the ammonia in guano unless both were dissolved in water. From some experiments which I have recently made, it appears that gypsum acts upon the insoluble part of guano, and produces a soluble sulphate; nothing more than perfect contact of the two compounds being effected by the water in which they are placed. After washing a portion of guano very frequently for several days, until every trace of its soluble salts was removed, I added 50 grains of gypsum to 100 grains of the insoluble residuum of the guano. In the course of two or three hours a decided action had commenced. The evaporation of a few drops of the water in which the gypsum and guano were placed, gave a large supply of microscopic crystals, and about 10 grains of soluble sulphates, the sulphate of ammonia being one, were ultimately obtained. My former short notice on this subject showed that the sulphuric acid of the gypsum fixes ammonia, if its salts be dissolved in water; and by the present experiment it appears that, under the action of gypsum, even insoluble portions of guano may be made immediately available for the food of plants. This effect, resulting from the perfect contact of two insoluble bodies, will seem to be the less surprising, if we bear in mind that even two elements, two of the metals, when placed in contact, not in water, but in atmospheric air, immediately liquefy each other.—*J. B. Reade, Stone, Aylesbury.*

Railroads.—Has it occurred to you what may be the effect of these railroad works that are everywhere interesting our properties, and absorbing our land? It is worthy of the consideration of those who are engaged in agriculture, what the results of this all-absorbing mania may be in regard to rents and rent-charge, and as affecting the aggregate produce? Farmers should be looking out; and the sooner they get leases of their landlords the better, I am inclined to think, for them and their families. The venerable Laurent, as in your newspaper of last week, may well protest, though, alas, in vain! And another in vain supplicates for the favourite and cherished Elm or Oak of his early care. Should the Colossus of *Roads* penetrate the park of Blair Athol and others, where the Queen and Prince Albert planted their pairs of Oaks, would they be spared? But the pocket, of course, before the refined pretensions of sentiment, and the M.P. will be the arbiter after all; and if he be a proprietor, we can see (without the aid of Lord Rosse's telescope), which way his vote will go. But consider what thousands of acres of land the rail has already taken out of all possibility of cultivation, and draw your own conclusions.—*An Early Contributor, and an Original Subscriber.*

Chidham Wheat.—I transcribe for you, from "Young's Survey of Sussex," published by the Agricultural Board in 1813, the account of the origin of this variety of Wheat:—"The farming world is certainly indebted to Mr. Woods (of Chidham), for a valuable acquisition, in bringing into cultivation, what with justice has been called, and is a new sort of Wheat, the Chidham White, or Hedge-wheat. The origin of it was this:—As Mr. Woods was occasionally walking over his fields, he met with a single plant of Wheat growing in a hedge. This plant contained 30 fair ears, in which were found 1400 corns. These Mr. Woods planted the ensuing year, with the greatest attention, in a Wheat field: the crop from these 1400 corns produced 8½ lbs. of seed, which he planted the same year, and the produce amounted to 43 gallons; this he drilled, and it yielded 25½ quarters, 9-gallon measure. Having now raised a large quantity of seed, he partly drilled, and in part sowed, the last produce broadcast, over rather more than 50 acres of land, and he gained 384 loads—26 loads of this quantity was sold for seed at 14*l.* 15*s.* per load. The Wheat, upon trial, was found to be so fine, that Mr. Woods had an immediate demand for a far greater quantity than he could spare for sale: 1792 turned out a bad yielding year, otherwise the last produce would have fully equalled 40 loads. With respect to the sample of Chidham Wheat, it is white, of a very fine berry, and remarkably long in the straw, so as to stand in a wet summer full 6 feet in height. The seed is now (1813), dispersed over Hampshire, Surrey, and other counties, and much cultivated about Guildford.—*J. S.*

The Cotswolds.—In your *Gazette* for Oct. 5, I find among your "Notices to Correspondents," in reply to "G.", you describe the soil of the Cotswold hills to be "poor, thin, and brashy." I have resided the greatest part of my life upon the Cotswolds, at Salperton, which is situated between Northleach and Andoversford, and though much of our soil is as you describe, I do not believe it varies more in any part of England. To that answer for it that in my parish we have not one ground without a variety of soils. Some of our stone brash is quite deep in soil (I am not speaking of the valleys), as you will suppose when I mention that I have grown many of the large Belgian Carrots, five pounds weight, without manure, upon a farm which was so wretchedly cultivated that I was obliged to take it in hand four years ago. We have, also, a good deal of very stiff clay, and still more of a very deep soil, called in the country a dead earthy soil, on which, as elsewhere, great benefit is derived from paring and burning, though I am sorry to say, some few landlords are, to the injury of their land and the ruin of their tenants, discontinuing it. You then say, "No cheese is made there." Of course not in the same quantities as in the vale; but I will answer for it that, upon at least one-third of our farms, cheese is made. Cheese has been made from time immemorial in my parish, and it is very highly spoken of by those who taste it. You then say, "Turnips are sown broadcast; but the farmers rarely use artificial manure." Now I should much like to know where you obtained your information, for it would almost puzzle you to find one farm where the Turnips are all sown broadcast, certainly in our neighbourhood; and I understand at the Cirencester Cattle Show, nearly all the competitors for the best field of Turnips, raised them with artificial manure, and if not upon the ridge system, by drilling upon the plain surface. I cannot call to my recollection one farmer who does not use some sort of artificial manure. There was one of my father's tenants who never had, and last year I persuaded him to let me have a few loads of straw, and pay him with bones, which bones I stipulated to put on with my drop-drill. I did this in a great measure to remove prejudice, and though we only put 4 bushels per acre with, I believe, about 16 of turf ashes, he has got better Turnips there than any part of the field with farm-yard manure; indeed, had it not been for the large grub, which has destroyed thousands of acres of Turnips upon the Cotswolds this year, he would have had a very fine crop. I was in great hopes somebody else would have taken notice of your paragraph, but this not being the case, I could not refrain from answering it myself. I will, if you wish it, give you some slight account of the Cotswold system of farming from time to time. [Thank you].—*T. B. Browne.* [You needed to have read "G.'s" communication, to have become qualified as judge of the accuracy of our answer to it. The statements as to cheese-making, and the use of artificial manures are, comparatively speaking, correct, *i. e.* but very little cheese is made, and but very little artificial manure—in the sense in which "G." employed the term—is used. We know that the drill cultivation of Turnips is rapidly acquiring general adoption on the Cotswolds, but that does not hinder us from admitting the truth of "G.'s" supposition, that broadcast culture still to a great extent exists.]

Allotments.—I have read with interest all that your columns have contained on this subject, and am myself endeavouring to pursue some such system in the village where I reside, convinced that it presents a very important means by which to improve the condition of an invaluable class of the community. The suggestion I have to offer, is therefore, made in no unfriendly spirit; yet I confess I am not without very strong misgivings that sooner or later, according as the system of providing the labourer with a patch of ground for his own cultivation may become established, advantage will be taken of his dependent state to turn this present well-intentioned scheme of good against him, and convert it into a medium by which still further to lower his condition. I fear that it will be made a handle to lower still further the wages of the agricultural labourer; that the farmer, taking into calculation the advantages which a labourer and his family may derive from the cultivation of his little allotment, will convert them into an element by which to measure the minimum, daily or weekly stipend on which a labouring man may subsist. The allotment system, by this perversion of its humane intent, may thus, in its ultimate effects, promote the very evil it is meant to correct, its first tendency being to increase population by improving the condition of the present generation, while, if my anticipations should unhappily be realised, its remote consequences will be a return of the privations and poverty consequent on insufficient wages, and operating upon a wider spread surface of society. The probability of the evil seems obvious than the preventive. It becomes, however, the duty of every friend to humanity to be alive to the possible consequences of a measure which now lives in the support of the most philanthropic spirits of the age.—*Basilicus.*

Professor Johnston's Lectures on Peat.—The following is an explanation of the great variety of opinion regarding the use of common salt as a manure. Here Farmer *A* in Dalston on the side of the hill facing the sea, applies salt to a considerable extent in various ways, but never found that it did him any good. *B* and *C*, in the inland valley, had also used it, and to very beneficial results. Farmers *A* and *B* meeting in the market-room, and amongst other subjects of discussion arises upon the use of common salt as a manure. *B* tells *A* that he has tried it often, and in different ways, and never could discover any difference in favour of the crops that had been salted beyond the lump that had not. *A* had, therefore, satisfied himself of its worthlessness, whatever another farmer made of it, and so made up his mind to use no more of it as only so much time and money thrown away. *B*, more than that, it has prevented wetting such manures as might have been of some benefit, and has thus lessened the purchase-money and carriage, damaged his pulling it on, and spiritual failure of my crops; that might have been much better had I used something else, and not depended upon it, I am a considerable loser, and have, therefore, learned a lesson I am likely to remember." Another which farmer *B* says, "I am rather surprised at your statements regarding common salt, as I have been using it for many years, and have always observed a very decided difference in favour of the crops where I applied it, and on that account I am likely to continue to use it while I am satisfied of its beneficial results." Another farmer from the sea aspect says, "I have used salt a good deal, and can confirm the statement of my friend from the same district, that it is useless as a manure, and have also made up my mind to give it up; experience and the evidence of my own senses, telling me it is good for nothing." In this way the discussion goes on, those from their side of the hill being against it, and those from *B*'s side, viz., in the valley beyond, as invariably for it, until the question whether salt is of any use as a manure is really put to the vote. The Professor declined upon the spot to enter into such an argument upon different opinions not within his knowledge of the causes. He called attention to the following, the quantity of common salt, contained in different soils, and explained the maximum amount that any land was likely to require of it; and the Con. the sea decomposing spirited by the winds the salt which comes in the spray and was carried on to the land was of considerable quantity, when it was found that houses as much as 20 miles inland had their windows incrusted with it, so that tracts lying within the influence of the sea-breeze could not be in want of it. The management of draughills then came to be considered, and the generally bad system pursued. He said they were generally placed upon the driest part of the steading, and if that was not dry enough, drains or gutters were carefully cut from them to some lower place, and from what he saw in the market, Brook, where the best and richest part of the manure found its way to the nearest river, and washed onwards to the sea. The Professor then said, "What would you think if, on your going home to-night, you found that the water had all drained away, and that nothing was left but the leaves? You could hardly complain; but under such circumstances you would have no more reason to do so than your farms have to complain; you waste your farmyard tea, and you carry to your land the leaves."—*A Subscriber.*

Two Crops per Annum.—In the counties of Berks and Oxford, Turnips or Rape is very often sown with Beans or Peas; the seed is sown sometimes between the rows with a small hand-drill, and sometimes broadcast just before the last hoeing; I have Tankard Turnips sown with Beans this season, now ready to be fed off with sheep, some of the roots weighing from 3lb. to 4lb. The crop of Beans was very good.—*J. C. C.*

Prevention of the Fly in Sheep.—I have heard that an excellent way of preventing sheep being struck with the fly, is to mix train oil and tobacco to a moderately thick substance, and then occasionally draw a brush down the back of each animal during the season that the fly is about. Once a month is said to be sufficient. Can you say if it is effectual, or will some practical farmer give his opinion on the subject?—*A. A.* [Your plan will very frequently succeed in preventing the attack of the fly, but a more simple and effectual method is the occasional application of coarse whale oil.—*W. C. S.*]

Fire-clay as a Manure.—Mr. James Anderson says, (p. 692, *Agricultural Gazette* 1840), Mr. Sprot planted two Potatoes with a large spadeful of well rotted, hatbed stable-dung, well incorporated with the soil; two others he planted about 18 inches from the above, incorporating with the soil an English pint of Garnkirk fire-clay. I do not think the experiment conclusive as to the extent of the fertilising quality of the Garnkirk fire-clay, for though this clay might make the soil more retentive or attractive of moisture, and so far of service to these two Potatoes, yet from their close proximity to the dunged ground, they probably received as much benefit from the effluvia that permeated from it to the dunged Potatoes did, while this proximity would, if the clay is attractive of moisture, which is probably its case, tended to deprive the dunged Potatoes of moisture, to which the stable-dung also assisted. And the dung been of the byre instead of the stable, and the distance greater, I think the result would have been different.—*J. M. Goodiffe.*

Hop Gardens.—I am about to commence a Hop-yard, but being myself inexperienced in the system, I have had recourse to my neighbours for information, all of whom invariably recommend the removal of all the sickly (or barren) plants, under the idea that as they never bear they are useless. I know practical men are to a degree right when they seem to be wrong, but I should have suspected that the perfection, if not the quantity of the weight of the Hop, would have been best secured by impregnation. I should, therefore, be much obliged if any one would favour me with your opinion on the point; I feel anxiously anxious what is the practice among the best growers in Kent, Sussex, &c., and particularly how many barren plants it would be desirable to have in every hundred. I presume it will be necessary to plant them singly, and not two or three plants together, as is the general custom. I am myself inclined to plan ten per cent. I should further be obliged by the names of the best kinds, Kent Hops especially; of the hardiest and best bearing, and in imitation of the name and address of the party from whom proper cuttings might be obtained. I understand Hop-growers themselves, and not hirelings, may provide them.—*Humulus, Bradford.*

How to stack Cabbages.—Peter Mackenzie tells us "the Cabbages are put in heaps in a manner like cast-iron bullets in an arsenal;" but as few English farmers have had the advantage of an education at Woolwich, and as many of those of the interior have not even seen an iron bullet, let alone an arsenal, they may not understand how a pile of balls is made. As it may also give Cabbage-growers more confidence in storing, to be informed that over a large tract of country it is generally done with success, I will state the practice throughout the province of Connaught and neighbouring parts. About a month before Christmas the Cabbages (the roots being cut off), are ranged as close as possible in parallel rows of any length—say six rows; on the tops of these, five parallel rows are ranged from these again four rows; on these three, then two, and one row finishes the heap; a little straw is placed over them to keep the earth from them, and they are covered about a foot thick with earth beaten down so as to exclude air and rain; they are thus finished off like the roof of a house; no straw or anything is mixed with them. Of course advantage is taken of a dry day; and it is better to lay the tops downwards, that any moisture may drain from them. The first rows may either be placed on the surface, or a pit may be excavated to the depth.—*F., Mr. Cobbaliffe.*

Sea Buckthorn.—Will your correspondent "M. D. P.," who, in your *Gazette* of the 26th of last month, alludes to the plant called Sea Buckthorn, favour us with some further particulars respecting it? From the properties he describes it to possess—of growing freely on sand-hills, and especially of not being liable to be attacked by rabbits—it would be most valuable in some localities. Will it grow and be useful as underwood, and in inland districts? Perhaps Mr. D. P., or some of your correspondents, will oblige us by describing it more particularly, and state if it is to be met with in any other parts than those referred to. Upon inquiry, I cannot find that it is known under the name in question.—*An Old Subscriber.*

A Correspondent, in the Number of the *Gazette* for Oct. 26, asks who is the author of the saying that, "whoever could make two ears of Corn, or two blades of Grass to grow upon a spot of ground where one only grew before, would deserve better of mankind, and do more essential service to his country, than the whole race of politicians put together." I beg to inform him that the King of Brobdingnag made the observation to Mr. Lemuel Gulliver.—*Ed. G.*

Societies.

ROYAL AGRICULTURAL SOCIETY of ENGLAND.

The Council resumed their sittings for the Session, at the Society's House in Hanover-square, on Wednesday last, the 6th of November. Present—William Miles, Esq., M.P., in the chair; Viscount Hill, Colonel Austen, Thomas Raymond Barker, Esq.; Samuel Bennett, Esq.; French Burke, Esq.; Humphrey Gibbs, Esq.; T. B. Brandreth Gibbs, Esq.; Stephen Grantham, Esq.; Henry Handley, Esq.; W. Fisher Hobbs, Esq.; W. H. Hyett, Esq.; John Kinder, Esq.; Francis Pym, Esq.; James Allen Ransome, Esq.; Professor Sewell, William Shaw, Esq.; and Professor Solly.

Henry Drummond, Esq., of Albury Park, near Guildford, Surrey, was elected a Governor, and the following gentlemen Members of the Society.

Talbot, Hon. and Rev. W. Chetwynd, Ommersley, Worcester.
Jones, W. Tilley, Gwynllyn, Aberystwith, S. W.
Gibaut, Moses, Mainland, St. Lawrence, Jersey.
Southampton, Lord, Whittlebury Lodge, Towcester, Northamptonshire.
Tiomson, Henry, Trinity, Colchester, Lancashire.
Roper, John Abbott, Buckingham.
Grant, John, Portsmouth, Devonshire.
Grant, Rev. Thomas, Vicar of Dolby, Daventry, Northamptonshire.
Smith, Benjamin, Coldham's Farm, Tonbridge, Kent.
Cunard, Samuel, Halifax, Nova Scotia.
Monmouthshire.
Galpine, Richard, Lymington, Hants.
Sanders, Samuel, Lockerd, Herts, Hampshire, Herts.
Williams, Leigh, Farnham, Surrey.

FINANCE.—Mr. R. Barclay, Chairman of the Finance Committee, laid before the Council the Report of the Society's funds on the last day of the previous month, from which it appeared that the amount of invested capital was 7209*l.* and the current cash balance in the hands of the bankers, 988*l.* This Report was then confirmed, and cheques ordered for the various payments recommended by the Committee.

COLONEL AUSTEN called the attention of the Council to the large amount of arrears of subscription still remaining unpaid, notwithstanding the constant reference of the Finance Committee to the subject, and the reduction of no less than 1223*l.* of arrears during the last six months; and he thought that some still more vigorous and decisive step would be taken by the Council to insure the payment of the subscriptions as they became due from year to year, and thus remove the inconvenient position under which the accounts of the Society were placed by the accumulation of unpaid payments, and the consequent accumulation of arrears.

Mr. Pym, Mr. French Burke, and Mr. Kinder, having stated the success which had attended the efforts they had made in their respective counties of Bedfordshire, Essex and Hertfordshire, as Honorary Collectors of the Society's subscriptions from the members residing within those districts, expressed their willingness to continue their exertions to the sure of such collection, and to aid the Council in extending the system of such friendly co-operation, through members of the Council, to other counties. Mr. Pym then gave notice, that at the Monthly Council to be held on the 4th of December next, he should move, "That county or district collectors should be appointed for the purpose of getting in the subscriptions of the Society."

ELECTIONS OF COUNCIL.—On the motion of Mr. RAYMOND BARKER, seconded by Mr. Shaw, the Council resolved unanimously, that Philip Pusey, Esq., M.P., Chairman of the Journal Committee, should be requested to accept the office of a Trustee of the Society, vacant by the decease of His Grace the Duke of Grafton. Mr. Thomas Lockley Meire, of Cound Harbour, near Shrewsbury, was elected a Member of Council, in the place of the late Mr. Edward Gough, of Gravel Hill, near Shrewsbury.

IMPLEMENTS AT SOUTHAMPTON.—Mr. PARKES, Consulting-Engineer to the Society, communicated to the Council the doubt and difficulty under which he this year laboured in drawing up his report on the trial and exhibition of Implements at the Annual Country Meeting of the Society, from the circumstance of his acting at Southampton simply as the mechanical referee of the Judges, and not as formerly as an actual judge himself—an arrangement which, to a considerable extent, placed him under the condition of an ordinary inspector of the implements, and excluded him from the more immediate communication with the judges at the trials which determined their awards, and which was essential to his being enabled to make a complete and satisfactory Report. The following resolution was then passed:—"That it is the opinion of the Council, after considering the letter addressed to them by Mr. Parkes, that Mr. Parkes should draw up the Report from the reports of the Judges, for which they are solely responsible; but that upon all trials which he himself viewed, it will be competent for him to make any remarks he may think necessary, as well as upon the whole mechanical appearance of the Show."

Mr. SHAW gave notice that at the next Monthly Council in December he should move:—"That the trials of implements be in future made at such time and place as the Society may find best adapted to the circumstances, and not confined to the Annual Country Meetings of the Society.

SHREWSBURY MEETING.—Earl SPENCER, Chairman of the General Shrewsbury Committee, addressed a communication to the Council in reference to the arrangements of the Annual Country Meeting, to be held at that place next year; and Mr. BRANDRETH GIBBS reported the result of his personal visit to Shrewsbury, and his interview with the owner of the fields intended for the trial of implements, and which had been now placed, agreeably with the instructions of Mr. Shelley and Mr. Miles, the stewards of that department, under proper cultivation for that purpose. Mr. Gibbs also reported that Earl Spencer and Mr. Taylor had undertaken the trial of the Wheat, selected at Southampton for cultivation in reference to the Society's prize.

PRIZE ESSAYS.—Mr. J. A. GORDON, of Naish, near Bristol, addressed a communication to the Council, in which he proposed to place the sum of 30*l.* at their disposal, as a prize for the best Essay on the Influence of Electricity on Vegetation. The Council ordered their thanks to be given to Mr. Gordon for this liberal offer, and referred the consideration of the subject to the next monthly Council. Mr. SHAW expressed his regret to find that all the Essays to which the prizes of the Society had been awarded, had not been published in the Journal; for, although the one in which he was himself much interested—"On the Mechanical Properties of the Plough"—had been placed, he was informed, in the hands of its lamented author, the late Rev. W. L. Rham, for revision and extension, and remained incomplete at the time of his decease, there were other Essays to which prizes had been awarded, but which had not yet been published.—The Chairman explained to Mr. Shaw, that, independently of the Essays, which it was thought not desirable to publish under their present form in the Journal, there were several others whose appearance was delayed in consequence of the extent to which the pages of the Journal had been occupied by the Prize Reports on the farming of the various counties already selected for consideration; that on the county of Norfolk having proved so voluminous that its author had preferred its entire publication on its own account, to the requisite abridgement of its details for the Journal.

ASHES OF PLANTS.—The MARQUIS OF NORTHAMPTON and Sir JOHN JOHNSTONE, Bart., M.P., communicated to the Council a proposal, on the part of the British Association, that the Society should join with that body, in contributing a sum of money from its funds for the purpose of obtaining a complete series of analyses on the ashes of plants, from various localities, to be made under the immediate superintendence of Professor Gregory, who had liberally placed his services on this occasion gratuitously at the disposal of the two Institutions. The consideration of this question was postponed until the January Council in December.

The communication of Mr. Hudson on his sowing machine having been referred to the Journal Committee, and the offer of a model accepted, thanks were ordered for the numerous donations made to the Society, and the Council adjourned for a fortnight, until Wednesday, the 20th of November.

FARMERS' CLUBS.

Cirencester.—At the last annual meeting of this Association, the following remarks were made:—Mr. Hammonds of Tunsheet, said that last year he sowed a field of Swede Turnips in rows. One part of the field he manured with good rotten dung from the fatting stalls, at the rate of 30 loads per acre. Close beside it he drilled in guano, at the rate of 2½ cwt. per acre. The Turnips where the guano was placed were the best up till the middle of the summer, which he fed them off, and the crop in that field this summer was quite as good where the guano was put as where he manured it with dung.—Mr. G. Wickens had used guano on meadow land, and one could tell to an inch where it was laid, the Grass was so greatly improved.—Capt. Aitchison spoke from experience of the effect of manuring with soot on his land. The eight-acre field, where the ploughing-match was held last year, he sowed with Wheat, and top-dressed it with soot, in the autumn, at the rate of 50 bushels to the acre, and he had a most excellent crop of Wheat, and a finer piece of young seeds he scarcely ever saw.—The chairman believed, in this part of the country, mould taken from hedges and mixed with dung or lime was a very favourite manure with the farmers. Now, it occurred to him that by spreading this mould over their land they sowed a great many weeds, else where did the great quantity of weeds found in the farmers' fields come from? He saw go where he would, a great many weeds, and he was inclined to think that the mould, taken from the ditches, although it might be valuable to the land, contained a great many weeds. He thought that artificial manures were preferable in this respect: they did no harm.—Capt. Aitchison was of opinion that the farmers were too apt to spare the labour of turning the mould heaps sufficiently often to destroy the weeds. His mode was to turn the mix hills three times at least, and he was satisfied it paid the farmer. Thus the whole of the seeds were brought into life and destroyed before being carried into the fields.

Saffron Walden.—The following are portions of a speech by Ph. Pusey Esq., M.P., at a late Meeting of this Society:—He said there was one subject that occupied the attention of the country—the improvement of the condition of the agricultural labourer; and on that point he would beg to throw out some considerations for them to pass their opinion upon. He would say that he thought credit was due to Lord John Russell for his endeavours to revive the old amusements of the peasantry of this country. He might quote a practical authority on the subject—the Speaker of the House of Commons—who told him in 1830, when outrages took place, that they would all remember that there were about 30 parishes in Hampshire, known as the cricket parishes, and in these parishes no disturbances occurred. Emigration was talked of as a remedy for the evil; but he thought those who talked of this were not aware that the population had flowed to Canada, the United States, and other parts, to the amount of 100,000 a year. He did not think this could be looked on as a national remedy for what was called the "surplus population." Then they had the allotment system proposed, and on that subject he would speak confidently. He was aware that there were objections to it on the part of the farmers; he found that was so when he carried it into effect 14 years ago; but that was passed away, and the farmers, he believed, no longer feared allotments. For the last 14 years he had had 400 or 500 allotment tenants, and it certainly had answered extremely well. But still, this must be regarded as a palliation; it was not a sufficient remedy for the present want of employment; that remedy was to be found in the employment by the landlord of the surplus population of the villages during the season, in permanent improvements of the soil. He learned this from his relative Lord Kinnaird, who, 30 years ago, used to employ a number of labourers in improvements on his estates; Mr. Pusey had done the same himself; and he believed, if he could get this principle established in every parish, we should hear no more for some years of a surplus population. He did not think gentlemen were aware of how far money would go in improvements. If they had men for 10*s.* a week for the winter months, for 300*l.* they might employ 50 labourers, and they would not only benefit them, but all the other labourers, because as a little corn thrown in would sometimes spoil the whole market, so if they withdrew these labourers they rendered employment better for all the others. Then the question came, Where were the landlords to find funds for this purpose? He knew this country well, and he knew there was not a place from Plymouth to Berwick in which landlords might not make improvements; but when the tenant was short of money, the landlord generally would be short of money too. But he would tell them how to find funds. There were many districts where there was a great superfluity, not only of useless but of mischievous timber, and if they would cut that

down, which excluded the sun and air and fed on the soil, and sell it, they would benefit the farmer and the labourer too by laying out the proceeds in under-draining the soil. There was another mode in which they might find money. He knew that on some properties a large sum was spent in the preservation of game. It was not at all unusual for the game to cost 500*l.* or 600*l.* a year; and if this were given up, the money would employ 100 able-bodied labourers in improving the property. This was another fund for the landlords of England to benefit the labourers, and the farmers at the same time. Still, if the landlord did his utmost he might not be able to find money sufficient for the purpose; but let him give security to the tenant, that if he will lay out his money in permanent improvement, he shall reap the reward of the outlay. This might be done by a lease, and it might be done without a lease, for they ought not to lay down an absolute rule, as leases were not universally applicable, and it was not desirable that the landlord should give up the land for 10 to 14 years to a man that was not able to do justice to it. But without leases there was a plan adopted in Leicestershire, by which they might give security for money expended in improvements. If a farmer boned his land, it was supposed that would not be exhausted in less than three years; and if the tenant left the first year, he received back two-thirds of the expense. Then if he clothed the land, that was not exhausted under ten years; and if he left it in five years, he received back one-half. Therefore, if the landlord objected to granting a lease, he said let him give security in this way for the outlay in permanent improvements on the land. There was another source of employment for the population—that was the breaking up of Grass land. He had broken up a great deal of Grass land himself, and he never repented of it. It appeared to him, that since the system of fatting cattle on artificial food Grass land had sunk in value. Now they would see at once the great increase of employment that would arise from breaking up these lands: they might reckon one labourer for 100 acres of Grass land, but it would take four to 100 of arable; and thus if they had 500 acres of Grass land, and broke it up, instead of five families they would employ 25 on it, which would considerably relieve the distress.—Mr. Edward Solly then entered deeply into the mutual benefits conferred by chemistry on agriculture, and *vice versâ*; and gave a short sketch of the progress of agricultural chemistry during the last few years, pointing out the value of science in all practical matters, and more especially drawing attention to those parts of Agriculture which were likely to be benefited by chemical science. He stated that phosphate of lime existed in large quantities in Wheat flour, and that it was necessary that a proper quantity should be afforded the plant, in order to bring it to perfection, as well as those materials necessary to the formation of starch and gluten. A gentleman named Lawes, had endeavoured to produce superphosphate of lime in large quantities by burning bones, and adding thereto sulphuric acid. This was an excellent manure. He could not, however, procure enough bones for his purpose. Professor Daubeny had visited Spain, at the request of the Royal Agricultural Society of England, and found phosphate of lime to exist there in large quantities, but the heavy expense of land carriage prevented its transmission to this country. It was, however, very probable that large quantities existed below the surface of the soil in this country, which had only to be brought up and spread upon their lands to excite fertility. He had, at the suggestion of Professor Henslow, visited a part of the east coast, where he had seen hundreds of tons of the required material in the shape of coprolites, one of which he held in his hand, though from its appearance no one would suppose that it contained the most essential manure for the production of both plants and animals. The value of phosphate of lime being known, chemists and others would seek everywhere for cheap and abundant supplies of it, and he had no doubt the search would be successful.

Reviews.

Practical Treatise on the Use of Peruvian and Ichaboe African Guano, &c. By J. H. Sheppard.

Another of the many pamphlets on this subject, to some of which we have already directed the attention of our readers. It is full of convincing testimonies to the value of guano as a manure, and it contains many useful directions how to apply it.

Miscellaneous.

On Ploughing Old Pasture Lands.—With the consent of the proprietor, two pieces of old turf of the second class were ploughed this spring, after proper drainage, in the parish in which I reside, and sown with Oats in the usual way. The produce of the first piece is estimated at 70 bushels per statute acre; the second piece, only a part of a field, produced 64 bushels per acre; and I have no doubt of the successful cropping of this land for a series of years, in the hands of the present good managing tenant. A part of this field, containing about fourteen acres, remained unploughed, and was not stocked in the spring, but mown for hay in July. The produce was gathered in, the whole amounting to about five tons, and but little herbage has grown since. It is easy to see the relative position of the occupier with regard to these two pieces of land, without going to figures. I am aware that it will be said the excessive drought that has lasted so long this summer is the cause of the failure of the Grass-land, and this is fully conceded, and this fact strengthens the evidence in favour of ploughing; inasmuch as it gives the farmer a greater control over the elements, in order that they may be made subservient to his interest. The master may pass over the Grass-land and make his silent remarks, but has no power or control over it. But not so in the other case: he can plough deep; he can hoe and harrow; thus pulverising the soil, rendering it capable both to attract and retain moisture; applying various [illegible] to the young plant [illegible] to what degree the [illegible] of the season, whether too excessive wet or drought, but little [illegible] with agriculture can [illegible] upon this head; the farmer will [illegible] it will [illegible] control [illegible] to [illegible] per [illegible] this description of land was put into Grass at a period when the population of this country was limited and small, and that there has been a vast accumulation of vegetable matter going on for generations, laid up in store by Providence for the supplies of the future, all of which might easily be converted into food for man, and a return given back which would produce food hereafter.—*Thomas Underwood, in the Northampton Mercury.*

Guano.—I could give the names of scientific farmers who applied guano three years back, that, without any better treatment than the ordinary mode, in the same field can be discerned on Clovers this year at a very considerable distance, where it was applied against the richest farmyard decomposed dung, in the same field; this I account for by having used genuine Peruvian guano—for African Ichaboe guano was not known at that time. The failure in so many instances where guano has been lately applied is from its spurious quality, the improper mode of application, the mixture of lime, &c.—*J. H. Sheppard, Chester, in the Farmers' Journal.*

Advertisement.—*R. A.*—The Advertisement will cost 5*s.* Shall we insert it?

Books.—*I. G. T.*—We cannot mention prices. Apply to any bookseller.

Book-keeping.—*E.*—We do not see that you need charge upon your returns for the year any per centage whatever on your invested capital—i. e. if it be all your own—before balancing your accounts. In *anticipating* the result of your proceedings for the coming year the case is different; for then, to insure accuracy, you must deduct from your estimated returns various per centages on different portions of your invested capital, according to what experience tells you will preserve its value from depreciation. Thus, 5 per cent. on the present value of your sheep must be deducted, for this will be required to replace the losses of the year by death or accident; 10 per cent. on that of your horses must also be deducted to cover the losses and injuries which *they* may sustain—and so on. At the end of the year, however, you have to collate facts, not to estimate probabilities, and if your valuations of stock be just, the simple difference between that at the beginning of the year + the amount of purchases and expenses during it, and that at the end of the year − the produce of sales during it will obviously represent the financial result of the year's proceedings.

Carcase.—*S. H.*—Chop it up, and cover the pieces with thick layers of your vegetable matter and pounded chalk; you had better not put clay or salt in the compost, unless you wish to retard the process of decomposition.

Dipping Sheep.—*H. F. Campbell.*—4 lbs. of Mr. Bigg's Composition suffices for 20 sheep. Mr. B.'s address is 15, Crawford-street, Portman square, London.

Fullers' Earth.—*Delta.*—Your remarks go to prove, not that fullers' earth contains alum, but that it contains alumina, which is only one of the three constituents of which alum is composed, the other two being sulphuric acid and potash. The effect of alum as a manure would more probably be owing to these than to the alumina which it contains.

Lucerne.—*D. H. L.*—One can hardly judge without seeing it. What has destroyed it? You may as well leave it till spring. You will be able to foresee the fate of your plant before it be too late for Swedish Turnips, especially if you can use Crosskill's clod-crusher, and so obtain a tilth in spite of weather.

Mr. Warne's Boxes.—*T. M. and a Subscriber.*—See to-day's Article, by Mr. Sproule.

Sea Mud.—*M. D. P.*—Certainly: have it ploughed before winter; the summer's fallow recommended was additional to this. Frost cannot be expected to deprive mud of excess of salt, except by increasing its porosity, and thus facilitating the action of future rains, in washing out its soluble ingredients. Lime decomposes salt, and may thus deprive it of some of its noxious properties; perhaps, however, muriate of lime and carbonate of soda, which are the resultant compounds from this process, may be as injurious in excess as common salt. We have no facts to determine the quantity of the latter substance, which may be beneficially applied per acre.

Spade Husbandry.—*Malum.*—Where can Dr. Yelloly's fork be obtained? The Vernon hoe has a dart-shaped blade, attached to a handle, with a swan-neck shaped termination. It is useful for opening drills for seed or sets, &c.

Trifolium incarnatum.—*R. G.*—Autumn is the proper season for sowing Trifolium incarnatum. Can any one give us his experience of it? Spring is the best season for manuring meadow land with guano. Apply a cwt. per acre.

Vetches.—*Paddy.*—In a luxuriant crop the lower parts of the plant will be certain to wither and rot. We know of no efficient remedy. Oats and Rye, sown with the seed, have but a slight tendency to support the plants.

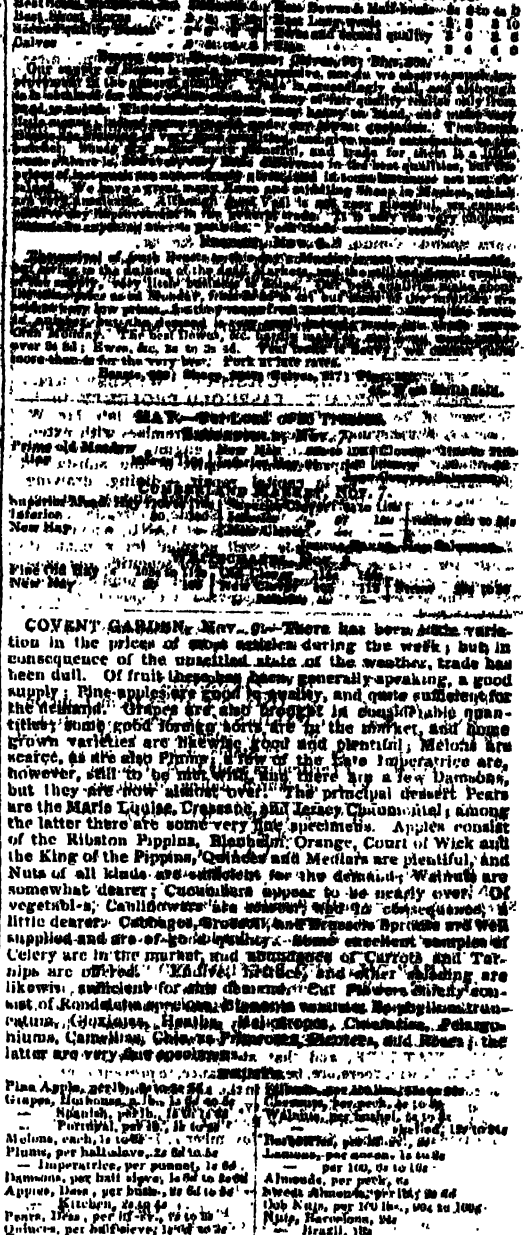
Warm or Fences.—*A Quiet Observer.*—Will you be kind enough to explain your meaning. What, in reference to quickets, is "preserving the spring."

*** As usual, many communications have been received too late.

Markets.

POTATOES.—Southwark Wednesday, Nov. 4.

In consequence of the coming goods the arrivals during the past week have been limited, which has caused a considerable clearance; several parts of cargoes of inferior sorts have been disposed of, and towards the end there was more money asked for the best Kents, but there were not sufficient sales made to justify an advance in the quotations, yet the demand was much better, and really sales were effected of the best samples at the following prices.



Perfection	60	to 70	Rose and Snow Flakes	—	—
Perth	50	—	Shaws	—	—
Fluckes	—	—	Whitneys	—	—
Early Devons	55	60	White	55	60
Late Devons	—	—	Blues	55	60
Cornwall	55	60	Chelmsford	50	—
Jersey Blues	50	—	White	55	60
— Whites	—	—	Prince Regents	50	60

HOPS, Friday, Nov. 6.

The Markets for fine Weald of Kent Hops keep advancing, and is full 5*s.* per cwt. dearer than last week.

The Duty is still estimated at 140,000.

Farlamond & Smith, Hop-Factors.

COVENT GARDEN, Nov. 6.—There has been little variation in the prices of fruit seldom during the week; but in consequence of the unsettled state of the weather, trade has been dull. Of fruit there has been generally speaking, a good supply; Pine-apples are good in quality, and quite sufficient for the demand. Grapes are also brought in considerable quantities; some good looking sorts are in the market, and home grown varieties are likewise good and plentiful; Melons are scarce, as are also Plums; a few of the late Imperatrice are, however, still to be met with, and there are a few Damsons, but they are now almost over. The principal dessert Pears are the Marie Louise, Crassane, and Jersey Gratioli; among the latter there are some very fine specimens. Apples consist of the Ribston Pippins, Blenheim Orange, Court of Wick and the King of the Pippins, Codlins and Medlars are plentiful, and Nuts of all kinds are sufficient for the demand. Walnuts are somewhat dearer; Cucumbers appear to be nearly over. Of vegetables, Cauliflowers are scarce, and consequently a little dearer. Cabbages, Greens, and Brussels Sprouts are well supplied and are of good quality. Some excellent samples of Celery are in the market, and abundance of Carrots and Turnips are offered. Kidney Beans, and other kinds are likewise sufficient for the demand. Cut Flowers chiefly consist of Dendrobiums, Cinerarias, Cinerea Primroses, Daisies, and Roses; the latter are very fine specimens.

Pine Apple, per lb.	2*s.*	to 4*s.*	Filberts, per 100 lbs.	—	—
Grapes, Hothouse, per lb.	1*s.*	to 6*s.*	Cocoanuts, per score	1*s.*	to 2*s.*

Rainwater and Lay.

TO GENTLEMEN, NURSERYMEN, AND GARDENERS.

LAVENDER-HILL NURSERY, WANDSWORTH-ROAD, Surrey County.

During the present month, sold by auction, unless previously disposed of by private contract, the Entire Stock of the extensive NURSERY GROUNDS, by order of the Executors, consisting of upwards of Two Hundred Thousand Forest and Fruit Trees, Evergreens, Flowering Shrubs, Roses, Herbaceous Plants, Bulbous Roots, Greenhouse Plants, Heaths, Geraniums, Cinerarias, Stock Plants, Seedlings, Cuttings, &c. &c. &c.

White Spanish Onion, Early Cauliflower, &c. &c.

The Nursery Grounds will be found in full bearing, and contain an extensive Collection of HERBS, Stock of Manure, and Implements of Cultivation, Garden Frames, Lights, Mats, Hand Glasses, Pots, Tubs, Boards, Labels, &c. &c.

The Stock of the present Tenant, consisting of about Two Hundred Loads of Manure, Hurdles, Fencing Stakes, Rails, Poles, &c. &c.

The Nursery Grounds will be found in full bearing, and contain an extensive Collection of HERBS, Stock of Manure, and Implements of Cultivation, Garden Frames, Lights, Mats, Hand Glasses, Pots, Tubs, Boards, Labels, &c. &c.

The Stock of the present Tenant, consisting of about Two Hundred Loads of Manure, Hurdles, Fencing Stakes, Rails, Poles, &c. &c.

White Spanish Onion, Early Cauliflower, &c. &c.

Descriptions of particulars will be duly given in future advertisements. Those wishing to view the Premises previous to the Sale, will be admitted by Tickets, which may be had of the Auctioneer, Lavender-hill, Wandsworth-road, Surrey County.

LAVENDER-HILL NURSERY, WANDSWORTH-ROAD.—IMPORTANT LEASEHOLD PROPERTY to be Disposed of, by order of the Executors of the late Mr. W. Pamplin, Nurserymen, those valuable Premises with extensive frontage, most beautifully and eligibly situated, and capable of much improvement, consist of the substantial DWELLING-HOUSE, in capital repair, containing drawing, and large sitting-rooms, Kitchen, Scullery, and Dairy, and large underground and other domestic offices; Stable, Coach-house, Sheds, and other buildings; about NINE ACRES of LAND, occupied as Nursery Grounds. The whole (well adapted for a moderate family, for a Nursery and Seedsman, or for scientific and experimental Agricultural purposes) will be Sold by public Auction during the present month, unless previously disposed of by private Contract.

For particulars apply to Mr. W. J. Lee, Clapham Common, or letter. Mr. Pamplin, 29, Bow-street, Soho.

TO MARKET GARDENERS.

TO BE LET AT EALING, SIX MILES from London, a Capital MARKET GARDEN of 11 Acres, well stocked with Fruit-trees, &c. Ready to the occupation of Mr. Samuel Everett. There is a House, with Stable and other conveniences on the premises. For particulars apply to Mr. Groves, Builder and House Agent, near the Church, Ealing, Middlesex.

TO FARMERS, BUILDERS, HAULIERS, HAY-MAKERS, and Others.

TO BE SOLD, by PRIVATE CONTRACT, about 200 Chaldron of CINDER ASHES, and About 2000 Loads MANURE, mixture of Night-soil and Sweepings of the Paved Streets, &c., Lying on the Premises, Albion-street, Rotherhithe, Surrey. Apply to Mr. Page, Jun., on the Premises.

N.B.—The Manure, &c. may be delivered into craft if required.

WEST BYFLEET, SURREY, AND BAGSHOT NURSERIES.

NOTICE.—The Business and these Nurseries, since the death of the late Mr. Samuel Waterer, carried on in the name of S. and C. WATERER by mutual agreement divided. That part of the Business at Bagshot, Surrey, is carried on by HOSEA WATERER, and that at Knaphill by JOHN WATERER. It will, therefore, be of importance, to prevent confusion, that correspondents be particular in the address and direct letters intended for the Knaphill Nursery, to Knaphill, near Woking Hill, near Bagshot, and those for the Bagshot Nursery, John Waterer, Nurseryman, Bagshot, Surrey.—November 7, 1844.

GRASS FARM.—WANTED, to RENT, upon very Moderate Terms, within nine miles of London and two of a Market-town, a GOOD DEVICE, in perfect repair; containing three or four Meadow Fields or nine Arable, and good Dwelling-house, with the usual Domestic Offices, &c. There must be from 30 to 50 Acres of good sound Meadow land adjoining, and the rent asked for them must accommodate itself to the altered state of the times.—Apply by letter, post paid, with full particulars, to F.R.C., Post-office, Farnham, Essex, Herts.

WHITNEY'S PATENT CLOTH for COVERING FRAMES, CUCUMBER or MELON PITS, &c.

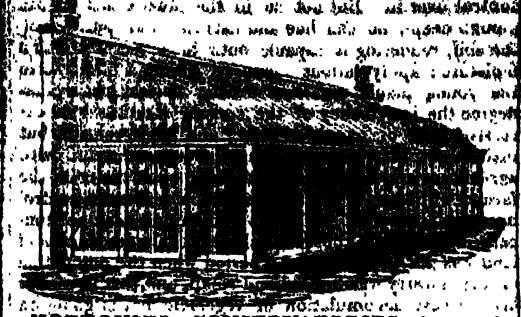
This Cloth is made expressly for the purpose of applying Whitney's Composition upon; and is much more durable than any other material. When coated it is beautifully white and transparent. The perfect success of Whitney's Composition for all Horticultural purposes cannot be more fully established than by stating that on the 10th of last March Hamburgh Vine was first introduced into a House covered with Cloth and coated with the Composition, and the last of Sept. a bunch of Grapes was cut weighing 16½ ounces, the fruit was finely coloured, and the flavour throughout very excellent. A sample was sent to the Editor of the "Gardeners' Chronicle" for his inspection. The Vine grew very luxuriantly, the foliage very fine, and the wood ripened exceedingly well. As a winter protection it is infinitely warmer than glass.

The PATENT CLOTH and COMPOSITION can be obtained of Messrs. Butler & Muckley, Covent-Garden Market; Hurst & M'Murtry, Leadenhall Street; Wright & Webber, Cornhill; Barclay & Sons, Farringdon Street, and Hennay & Co., Oxford Street.—Wholesale and Shipping Agent, Mr. Bailey, Wolverhampton.

SLATE WORKS, ISLEWORTH, MIDDLESEX.

THE following Articles, manufactured in Slate for Horticultural purposes, may be seen in use at Worton Cottage, upon application to the gardener (Sundays excepted).

Tank Covers	Shelving for Frames
Cisterns	Boards for Balconies and Verandas
Shelves	Ridging
Garden-Edging	Orange Tubs, Flower Boxes, &c.



EDWARD BEAN will be happy to answer any inquiries, either personally or by post.

STEPHENSON AND CO., 61, Gracechurch-street, London; and 77, New Park-street, Southwark, Inventors and Manufacturers of the improved CONICAL and DOUBLE CYLINDRICAL BOILERS, respectfully solicit the attention of scientific Horticulturists to their simple, approved method of applying the Tank System to Pinehouses, Propagating Houses, &c. by which atmospheric heat as well as bottom-heat is secured to any required degree without the use of pipes or flues. S. & C. have also to state that at the request of numerous friends they are now making their Boilers of Iron as well as Copper, by which the cost is reduced. These Boilers, which are now so well known, especially require description, but to those who have not seen them, prospectuses will be forwarded as well as references of the highest authority; or they may be seen at most of the Nobility's seats and principal Nurseries throughout the kingdom.

S. & Co. beg to intimate to the Trade that at their Manufactory in New Park-st., every description required for the construction of Horticultural buildings, Stoves, &c. for heating them, may be obtained upon the most reasonable terms agreed.

Conservatories, &c. of Iron or Wood, erected upon the most ornamental designs. Balconies, Palisading, Field, and Garden Fences, Wire Work, &c. &c.

COTTAM AND HALLEN, ENGINEERS, IRONMONGERS, &c., &c., No. 2, Whitby-street, Oxford-street, London, and at Cornbrook, near Manchester,

HOTHOUSES, CONSERVATORIES, &c., made upon the most improved principle, either of Iron or of Iron and wood combined, which can be fixed complete in any part of the Kingdom, at very low prices.

HOT-WATER APPARATUS for heating Hothouses, Conservatories, and Greenhouses, Churches, Public or Private Buildings, &c., with Cottam's Patent or Rogers's Boilers. After 15 years' experience, and having fixed upwards of 2000 Apparatus for the above-mentioned purposes, and by various improvements which they have made during that time, C. and H. can with confidence undertake the erection of similar Apparatus upon the most extensive scale.

Materials may be had for those who wish to fix their own Apparatus.

THE TANK SYSTEM on an improved principle, that will heat the house at the same time, without pipes.

IRON HURDLES, best Wire for Strained Fencing, Ornamental Iron and Wire-work, Garden Chairs, &c., &c., and every description of Implement for AGRICULTURAL and HORTICULTURAL PURPOSES.

Show Rooms at their Manufactory, 2, Winsley-street, Oxford-street, where a large assortment of the above can be seen.

HOT-WATER APPARATUS FOR HEATING HORTICULTURAL BUILDINGS, DWELLING-HOUSES, CHURCHES, and MANUFACTORIES, upon improved principles, and at very moderate charges, erected by DANIEL and EDWARD BAILEY, 272, HOLBORN.

D. and E. Bailey having devoted much time to the consideration of this subject, and had much experience in the erection of apparatus for the above-mentioned purposes, have, by improvements suggested in their practice, rendered their mode of heating not only very efficient, but very simple, and have combined durability in the apparatus with economy in the charge. They have erected apparatus in England, Scotland, and Ireland, for many noblemen and gentlemen, and have had the honour to be employed by the Horticultural Society of London, in executing the works of their splendid Conservatory, lately erected at Chiswick.

D. and E. Bailey also construct in metal all descriptions of Horticultural Buildings and Sashes, and invite noblemen, gentlemen, and the public to an inspection of their various drawings and models, at 272, Holborn, where they have the opportunity of exhibiting, amongst other metal works, an extremely complete and convenient kitchen apparatus, or range, adapted for the continued supply of hot water, and an arrangement of the oven more complete than has hitherto been brought before the public.

D. and E. Bailey were the first to introduce metallic curvilinear houses to horticulturists, and can refer to the Conservatory attached to the Pantheon as one of their works, besides many others in this country and on the Continent.

D. and E. Bailey have prepared a quantity of the Galvanic Plant Protectors, which are now ready for immediate delivery; they beg to introduce to public notice a new Trough Pipe, for Orchidaceous or other Houses where vapour is constantly, or at intervals required, and which may be seen at their Manufactory.

WIRE-WORK, HOT-WATER APPARATUS, GREEN-HOUSES, &c.

ST. THOMAS BAKER, MANOR-HOUSE, MANOR-PLACE, KING'S-ROAD, CHELSEA, Manufacturer of INVISIBLE WIRE-FENCE, to resist Grazing Stock, and rendered Rabbit-proof. WIRE-WORK in Trainers, Arches for Walks, Bordering, Flower Stands, Pheasantries, &c. HORTICULTURAL BUILDINGS, Green and Hothouses, Conservatories, &c. The same heated by HOT-WATER APPARATUS, on improved and economical principles.

Parties waited on in Town or Country, and Drawings and Estimates free. Work for the Trade as usual.

Ward's Cases, or Domestic Greenhouses.

IMPORTANT TO AGRICULTURISTS, &c.

ANALYSES of SOILS, MANURES, and all AGRICULTURAL PRODUCTS, are conducted by Messrs. Mitchell and Frain (late Mr. Mitchell's), Analytical Chemists, with the view of ascertaining whether the Soil, in which it is proposed to grow any particular crop, contains all that is necessary to produce a luxuriant vegetation; also to estimate the relative value and purity of Manures, and the comparative worth of Farm Produce in general. Gentlemen instructed in Agricultural Chemistry. The course will comprehend the Elements of Analysis.—No 84, Hawley-road, Kentish Town.

MR. LAWES' MANURES,—Mixture for Wheat, 7l. per ton; Super-phosphate of Lime, 7l. per ton. To be had at the Factory, Deptford Creek, near London.

Super-phosphate of Lime, in a concentrated form, may also be procured at Messrs. Warner's, 28, Cornhill, in 7lb. packets, price 1s.

GUANO (GENUINE PERUVIAN & BOLIVIAN) ON SALE, BY THE ONLY LEGAL IMPORTERS, ANTONY GIBBS AND SONS, LONDON; Wm. J. MYERS AND CO., LIVERPOOL;

And by their Agents,

COTESWORTH, POWELL AND PRYOR, LONDON; GIBBS, BRIGHT, & CO., LIVERPOOL and BRISTOL.

47, Lime-street, Nov. 1, 1844.

GUANO for SALE, in Bags of 1 cwt. each, just landed, at the Warehouses of the Agricultural Company, 21 and 26, Billiter-street.—Successive years' experience and the opportunity have proved that Genuine Guano is the simplest, cheapest, and most powerful within the reach of the Agriculturist. The only reasonable anxiety which now remains is to procure the Genuine Article, and to obtain such practical directions for using the Manure as shall fully develop its productive powers. To secure to buyers these indispensable requisites, with each purchase will be given a warranted chemical analysis of quality, and also a copy of the recently published Pamphlet, "Practical Instructions for using Guano as a Manure, illustrated by Practical Results."

Large parcels will be delivered direct from the ship or waterside premises; smaller quantities may be had at the warehouses, 21 and 26, Billiter-street, or delivered within any reasonable distance at a trifling additional cost. Apply to James Clare, 24, Billiter-street.

LIQUID MANURE.

ENGLAND INDEPENDENT OF THE WORLD FOR CORN.

THE Attention of the Agricultural Interest, at this important crisis, is requested to the great importance of LIQUID MANURE, and the ease with which it may be appreciated by the use of FOWLER'S PUMPS, made expressly for the purpose, either portable or fixed; Garden, Slulp, and Barge Pumps also fitted for Distillers, Brewers, Soap-boilers, and Manufacturers for hot and cold liquors. Pumps kept for hire, for Gentlemen's Gardens and Wells. Buildings heated by Hot Water, for Horticulture, and every variety of manufacturing purposes.

The Pumps supplied on advantageous terms, by Benjamin Fowler, Engineer, &c. 62, Dorset-street, Fleet-street, London.

DR. HALLETT'S DRY SOLUBLE FERTILIZER is, especially in this year, the cheapest Manure to use, for there is a great deficiency of the Phosphates and other Salts of Ammonia, which all knowledge powerful stimulants. They are fairly entitled to the Subject of Fig. 1 in Turnips. (see No. 33 of the "Gardeners' Chronicle," &c.). 5 cwt. of either has been found equal to nearly 20 tons of ordinary horse-manure. They are applicable to all sorts of field and garden crops. No. 1 for heavy top growth, as Corn; Hops, &c. No. 2 is for all roots, and a sure preventive of the Fly in Turnips. Price of each, 10l. per ton, or 1s. per cwt.

DR. HALLETT'S CONCENTRATED LIQUID FERTILIZER is extensively used by Gardeners for improving the size and flavour of fruits and vegetables, and the luxuriance and perfecting the seed of flowers. Sold in quarts at 1s. 6d., and in bottles, six times the size, at 7s. 6d. Each quart requires 32 gallons of water, to reduce it for use.

Agents for the above—London—Mr. Fothergill, Wardour-street; Mr. R. Hallett, the Factory, Bermondsey Street, Tooley-street; Messrs. Warner & Warner, 28, Cornhill; Hurst & M'Murtry, 6, Leadenhall-street; Winstanley, Pooley, Pace & Co., St. Peter's Alley, Norfolk—Buffard and Ward, Norwich. Suffolk—Mr. W. Bevans, Oxford. Leicester—Matthews & Co. Gloucestershire—Mr. Betterton, Fairford. Devonshire—Mr. Seward, Plymouth. Wilts—Mr. G. King, Devizes. Glasgow—Mr. D. T. Jackson, Hartlepool, Sunderland, Stockton, and Newcastle—Pace & Co, Dundee—Green and Co. Further respectable Agents wanted.

CHEAP AND DURABLE ROOFING.

BY HER MAJESTY'S

ROYAL LETTERS PATENT.

TO GARDENERS, NURSERYMEN, AND OTHERS.

F. M'NEILL & CO., of Lamb's Buildings, Bunhill-row, London, Manufacturers, and only Patentees of the IMPROVED PATENT ASPHALTED FELT, for Roofing Houses, Sheds, Verandahs, &c., and for Protecting Plants, and Covering Garden Frames, beg to call the attention of Gardeners and others to their superior article, which has been exhibited at the Great Agricultural Shows of England, Scotland, and Ireland, and OBTAINED the Prize, for being the most cheap and suitable for roofing, &c. It has been tested, in the gardens of several noblemen and gentlemen in the neighbourhood of London, and in different parts of the country, to which Testimonials can be referred. The Felt is impervious to rain, snow, and frost, and is a non-conductor of heat and sound. Its advantages are Lightness, Warmth, Durability, and Economy.—Price ONLY ONE PENNY PER SQUARE FOOT.

Samples, with directions for laying on, and testimonials of its merits, sent free to any part of the town or country.—Patent Felt Works, Lamb's Buildings, Bunhill-row, London.

TANNER'S VITREOUS CLOTH, A SUBSTITUTE for GLASS for HORTICULTURAL PURPOSES.—The above recommends itself to the notice of Gardeners and Horticulturists, as producing plants superior to Glass, at a less expense. The support the Proprietor has received from very many highly respectable Florists encourages him to consider that his labours have not been misapplied in bringing before the public an article so generally required. Price of cloth, 7-8ths of a yard wide, thin 3s. 6d. per yard; stout, 4s. 1 yard wide, 3s. 6d. Price of Plaid (for rendering the cloth still more lengthened service), 4s. 6d. and 5s. 6d. per yard. Manufactured only by N. W. Tanner, Chemist, Exeter; and Sold by Messrs. Butler and Muckley, Covent-garden, London; Mr. Cunningham, Paradise-street, Liverpool; Messrs. Lucombe and Pince, Exeter Nursery.

AGRICULTURAL DRAINING.—THE DERBY LEVEL.—The attention of persons draining their land is directed to this cheap but simple instrument, presumed to be all that can be required for the purpose, and to price such as to place it within the reach of all. To be had of the Maker, J. Davis, Cattle-in, Derby.

DRAIN TILES, SOLES, &c.—A regular supply can now be had of the above, and at moderate prices, at Ainslie's Patent Drain Tile Works, Alperton, near Ealing, Middlesex.

Alperton is eight miles west of London, and about three miles from Acton, Ealing, and Harrow. The Works being on the banks of the Grand Junction Canal, Tiles, &c., can be barged at a cheap rate, to any distance on the line.

All communication to be addressed "Alperton Tile Works, near Acton, Middlesex."

DRAINING OF LAND.—THE WORKMAN'S LEVEL, invented by Mr. Barnes Denton, is made and sold by Messrs. Jones, Opticians, 30, Lower Holborn, London.

IMPROVED ROOFING FELT.

McKIBBIN'S PATENT ROOFING FELT is particularly applicable as a substitute for Slate, Tarpaulin, Thatch, and other Articles used for Roofing, from its Economy, Durability, and Lightness. It is quite impervious to wet and damp, resists the heat of the sun, and is a non-conductor of heat or cold. Besides the economy in repairs, the timber where it is used may be so light as to save the whole expense. It requires no other coating, and by attention to printed directions may be applied by a common labourer. It is free from smell, age and contraction, like zinc, and requires neither painting nor coating. It is now in very general use for Roofing Houses, Verandahs, Sheds, Workshops, Pigeon-cotes, Railway Stations, Icehouses, &c. &c., and for protecting Plants, covering Garden Frames, Corn, and Hay Ricks, the top and sides of Stump-fences; and to Emigrants it provides a cheap, warm, durable, and portable Roof.

This Improved Roofing Felt is much more durable than the common Felt, made as it is thus, without tarring, like it or other materials in continuous lengths, to be stripped by storm; and being fastened down at the overlaps only, the wet cannot percolate through the nailholes.

Sold in sheets 32 inches by 36, at 6d. each (being less than 2s. 6d. per square of 100 feet).—Apply to H. C. Bowden, Agent to the Manufacturers, Kent Lodge Chambers, Leadenhall-street, London.

AGRICULTURE, COMMERCE, NAVIGATION, the CHURCH.—E. SAVORY and SONS, Goldsmiths, 14, Cornhill, London, opposite the Bank, have finished a few Splendid Pieces of PLATE, suitable for Presentation to Gentlemen connected with either of the above pursuits or professions, to which they invite the attention of committees who are in search of valuable testimonials for such occasions.

THIS DAY IS PUBLISHED,

THE BOOK OF THE FARM; detailing the Labours of the Farmer, Farm Steward, Ploughman, Shepherd, Hedger, Cattle-man, Field-worker, and Dairymaid. By HENRY STEPHENS, F.R.S.E. In three large volumes royal octavo, price 2l. 10s., illustrated by 23 Engravings on Steel, and upwards of 600 on Wood.

ADVERTISEMENT OF THE PUBLISHERS.—Before the publication of the BOOK OF THE FARM there was no Work to which the Student of Agriculture could be referred, as giving, in full detail, the various operations to which his attention would be directed in the course of the year. Such a work has long been a desideratum to the practical Farmer; and in the present volumes it has been the object of the Author to supply it. Commencing with the end of the Agricultural year, when the crops are reaped and housed, he sets out with what may be called the preparatory labours for the ensuing season; the reader being thus led on from month to month, and taught what labours should be in succession undertaken; why at that particular time; how these can be best performed, and with the smallest cost of money or time; and also the data by which the master may ascertain that his work has been efficiently performed. Nor has it been only to the primary operations of the Farm that the Author has limited his instructions. Almost every concomitant topic of subjects, which it should be the interest of the Farmer to know, has been brought forward and systematically discussed; and separate sections—we had almost said treatises—have been devoted to the mystery he necessary to be learned by the bailiff, the weather-seer, the hedge-planter, the ditcher, the drainer, the plough-man, the cattle-feeder, the stock-keeper, the drover, the pig-killer, the miller, the thatcher, up to the grieve or general overseer of the farming operations. In brief, it has been the great object of the Author, while endeavouring to make his Work as systematic and perfect as possible, that no subject, either of primary importance or collateral interest to the Agricultural Student or practical Farmer, should be left undiscussed; and the utmost pains has been taken that the information given should be brought down to the latest and most approved discoveries in all the departments.

SUBJECTS TREATED OF IN "THE BOOK OF THE FARM."

INTRODUCTORY.—The Difficulties which the young Farmer has to encounter at the outset in learning practical Husbandry—The Means of overcoming those Difficulties—The kind of Information to be found in existent Works on Agriculture—The Construction of the "Book of the Farm"—The existing methods of learning practical Husbandry—The establishment of Schools for Instruction in practical Agriculture—The Evils attendant on Landowners neglecting to learn practical Agriculture—Commercial Farms as places for Instruction in Farming—Advice to Young Farmers who intend Emigrating as Agricultural Settlers to the Colonies—The kind of Education best suited to Young Farmers—The different kinds of Farming—Choosing the kind of Farming—Selecting a Tutor Farmer for Teaching Farming—The Pupilage—Dealing with the Details of Farming—The Steading or Farmstead—The Farm-house—The Persons who Labour the Farm.

WINTER.—The Weather in Winter—Climate—Observing and recording Facts—Soils and Subsoils—Enclosures and Shelter—The Planting of Thorn Hedges—The Plough—The various Modes of Ploughing Ridges—Draining—Yoking and Harnessing the Plough, and of Swing trees—Ploughing Stubble and Lea-ground—Trench and Subsoil Ploughing, and Moorband Pan—Drawing and Stowing Turnip, Mangold Wurzel, Cabbage, Carrots, and Parsnips—The Feeding of Sheep on Turnips in Winter—Driving and Slaughtering Sheep—Rearing and Feeding Cattle on Turnips in Winter—Driving and Slaughtering Cattle—The Treatment of Farm horses in Winter—Fattening, Driving, and Slaughtering Swine—The Treatment of Fowls in Winter—Threshing and Winnowing Grain, and of the Thrashing-machine—The Wages of Farm-servants—Corn Markets—The Farm Smith, Joiner, and Saddler—The Forming of Dunghills, and of Liquid Manure Tanks—Winter Irrigation.

SPRING.—Ewes Calving, and Calves—The Advantages of having Field-work in a forward state—Cross-ploughing, Drilling, and Rubbing Land—Sowing Spring Wheat and Grass Seeds—Sowing Beans, Peas, Tares, Lucerne, Saintfoin, Flax, and Hemp—Switching, Pruning, and Water-Tabling Thorn Hedges—Hiring Farm Servants—Sowing Oat-seed—The Lambing of Ewes—The Training and Working the Shepherd's Dog—Sowing Barley Seed—Turning Dunghills and Composts—Planting Potatoes—Breaking in young Draught-horses—Sows Farrowing or Littering—The Hatching of Fowls.

SUMMER.—The Sowing of Turnips, Mangold-Wurzel, Rape, Carrots, and Parsnips—Repairing the Fences of Grass-fields, and the proper Construction of Field Gates—The Weaning of Calves, Bulls, and the Grazing of Cattle till Winter—Mares Foaling, Stallions, and Horses at Grass—Sheep-washing, Sheep-shearing, and Weaning of Lambs—Rolling the Fleece, and the Qualities of Wool—The Making of Butter and Cheese—Weeding Corn, Green Crops, Pastures, and Hedges, and Casualties to Plants—Haymaking—Summer Fallowing, and Liming the Soil—Building Stone Dykes—Embankments against Rivulets—Forming Water Meadows—Breaking in young Saddle-horses.

AUTUMN.—Pulling Flax and Hemp, and the Hop—Reaping Rye, Wheat, Barley, Oats, Beans, and Peas—Carrying in and Stacking Wheat, Barley, Oats, Beans, and Peas, and of the Construction of Carts—Drafting Ewes and Gimmers, Tupping Ewes, and Bathing and Smearing Sheep—Lifting and Pitting Potatoes—Sowing Autumn Wheat, and the Construction and Principles of Agricultural Wheel Carriages.—Eggs—Rotation of Crops—Fertilising the Soil by means of Manures—The Points possessed by the Domesticated Animals most desirable for the Farmer to cultivate—Making Experiments on Farms—Destroying and Scaring Vermin on Farms—Looking at a Farm; its Rent; its Lease; its Stocking; the Capital required for it—Improving Waste Land—Farm Book-keeping—The Conveniences of the Cottages of Farm Servants—The Care to be bestowed on the Preservation of Implements—Index.

WILLIAM BLACKWOOD and SONS, Edinburgh and London; and Sold by all Booksellers.

Price 1s., free by post,

Publishing in Weekly Numbers, price 6d. each, and in Monthly Parts,

THE MYSTERIES OF PARIS; a new and splendid Edition, adapted to the English reader. Illustrated with upwards of 200 Engravings on Wood of all the characters, Scenes, Costumes, and Localities described in this extraordinary Work, executed expressly for this edition, by the first Artists in Paris. Under the Superintendence of Mr. Charles Heath.

Already published Parts 1 to 5 and Numbers 1 to 24.

"This work is continued with unflagging spirit. We never saw a series of more life-like illustrations. The most finished effects are produced without trick or elaboration. These is the highest art with what seems to be the most rude and careless vigour. In this the French designers are incomparably superior to those of every other country. Nor do we know a better study for their peculiar effects than this illustrated *Mysteries of Paris*."—*Examiner*.

CHAPMAN and HALL, 186, Strand.

Just published, price 1s., or post-free, 1s. 4d.,

A COMPLETE READY RECKONER, for Measuring and Valuing Hay Ricks, with very plain Instructions for taking the Dimensions, and for judging the Density of the Hay, by EDWARD REDE, Land Surveyor, Sunbury, Middlesex.

Published by GILBERT, London; and will be forwarded by the Author, post-free, to any part of the kingdom, on the receipt of 1s. 4d., or an equivalent number of postage stamps, in a pre-paid letter.

SUBSCRIPTIONS

FOR THE

NATIONAL TESTIMONIAL

TO

MR. ROWLAND HILL,

AUTHOR OF THE PENNY POSTAGE,

WILL CLOSE ON THE 30TH OF NOVEMBER.

Of all the sources of income stated in the recently published Quarterly Returns of the Public Revenue, none exhibit *so large* a proportionate increase as the *Post Office*. On the year's net Revenue, the Customs have increased at the rate of about 10 per cent., the Excise 1½ per cent., the Property Tax 2 per cent., while the *Post Office Revenue*, under its almost nominal rate of a penny, has increased above 15½ per cent., and the increase on the quarter has been even as much as 25 per cent.

These cheering results show that (though the *plan of Penny Postage* is yet but *imperfectly tried*) the *complete restoration* of the Post Office Revenue to its amount before the Penny Postage was adopted is not an event far distant, if it be fully and honestly carried out; and the *City of London Mercantile Committee on Postage* desire to impress these satisfactory results most emphatically upon the Public, in announcing the *approaching close* of the National Testimonial to Mr. Rowland Hill. *All* parties are unanimous upon the great *moral* and *commercial* advantages of the *Penny Postage*. Its expediency as a *financial* step has been the *sole* ground of question; but now, even this *can scarcely be doubted*; for, let it be remembered, that the Old Postage Revenue had been absolutely *stationary* for twenty years,—retrogressive, in fact, if we consider the increase of population, education, and commerce during the period. The change which Penny Postage has effected, is to make the *Post Office Revenue* the *most buoyant* source of National Income, bidding fair to become more profitable than it has ever been. The Committee, therefore, call upon the Public to reward, with suitable gratitude, the Author of this great and triumphant measure.

The Committee have the satisfaction to announce that the Subscriptions, headed by the chiefs of political parties and of commercial wealth, already reach 10,000*l.*; but 10,000*l.* cannot be held to be a sufficient *national* reward for such *national* services. The Committee therefore urge upon the *nation at least to double* this sum. If every letter-writer, for only a single week, would pay a twopenny instead of a penny rate for his letters, the amount, and more, would be raised. In proportion as the public show their gratitude to Mr. Hill, so they strengthen the chances for the complete adoption of his plan, *now but partially carried out*. Its perfection will bring greatly-increased convenience to themselves, and increased advantage to the Post Office Revenue.

Never have the services of any *Public Benefactor* been *requited* as Mr. Hill's have been. Quitting a permanent situation for a *temporary* public engagement, to carry out his plan, Mr. Hill's services, whilst his plan was yet not carried out, were dispensed with, and he received the following acknowledgments of his merits, and—*nothing more*.—

"I gladly avail myself," writes the present Chancellor of the Exchequer, "of the opportunity of expressing my sense of the satisfactory manner in which, during my tenure of office, you have discharged the several duties which have been from time to time committed to you." "I entertain," writes Sir Robert Peel (who has also subscribed 10*l.* to the Testimonial), "a due sense of the motives by which your conduct, in respect to Post-Office arrangements, has been actuated, and of the zeal and fidelity with which you have discharged the duties committed to you."—Mr. Trevelyan, on behalf of the Lords of the Treasury, writes thus:—"I am also commanded by their Lordships to take this opportunity of stating, that they consider it due to you, on the termination of your engagement with the Government, to express to you the approbation with which they have regarded your zealous exertions in the execution of the duties which have been intrusted to you; and how materially the efficiency of the Post Office arrangements has been promoted by the care and intelligence evinced by you in the consideration of the various important questions which have been referred to you."

Under these circumstances the Committee call upon the *Public* to come forward with due generosity, and reward Mr. Hill themselves, as the *unrequited Inventor* of the *great measure of Penny Postage*—a measure which has opened the blessings of free correspondence to the Teacher of Religion, the Man of Science and Literature, the Merchant and Trader, and the *whole British Family*, especially the *poorest* and most *defenceless* portion of it;—a measure which is the *greatest boon* conferred in modern times on *all the social interests* of the *civilized world*; for Penny Postage is spreading its influence throughout Europe and reaching even Russia. The Committee rely on the gratitude of their countrymen, and feel sure that this, their last appeal, will not be made in vain.

(Signed) GEO. LARPENT, Chairman.

Subscription Cards, and every information, &c., may be obtained on application to the Secretary, Mr. GEORGE WANSEY, Solicitor, 3, Moorgate-street, London.

Printed by WILLIAM RICHARDS, of No. 6, York-place, Stoke Newington, and FREDERICK MULLETT EVANS, of No. 7, Church-row, Stoke Newington, both in the county of Middlesex, Printers, at their Office in Lombard-street, in the precinct of Whitefriars, in the City of London; and published by them at the Office, No. 5, Charles-street, in the parish of St. Paul's, Covent-Garden, in the said county, on each.—Advertisements and Communications are to be addressed to the Editor.—Saturday, November 9, 1844.

LARGE STOCK OF SEEDLINGS.

W. AND T. SAMSON, Kilmarnock, Ayrshire, have a large stock of the following plants, which they will dispose of at low prices:—

American Arbor-vitæ, 2 years old	50,000	Larch, 1 year old	1,000,000
Ash, 1 year old	200,000	Quercus macrocarpa, 1 year old	15,000
Beech, 1 year old	1,500,000	,, palustre, 1 yr. old	25,000
Bullace, wild, 1 yr. old	5000	,, rubra, 1 yr. old	5000
Elm, 1 year old	200,000	,, tinctoria, 1 yr. old	6000
Holly, 1 year old	150,000	Scots Fir, 2 years old	1,000,000
Hornbeam, 1 year old	150,000	Sloe, or Blackthorn, 1 year old	150,000
Juniper, common, 1 year old	30,000	Spruce, 2 years old	1,000,000
Quercus coccinea, 1 year old	100,000	Thorn quicks, 1 year old	1,500,000

They have also a large quantity of transplanted Azalea pontica, American Arbor-vitæ Evergreen Privet, Irish Yew, 1½ foot, Double Nedthorn, fine Plants, &c. &c., which they are inclined to sell cheap.

SHILLING'S EARLY GROTTO PEA.

THE above PEA possesses advantages over every other for autumn sowing, being quite hardy, very prolific, and much larger than any other early Pea. See *Gardeners' Chronicle*, 25th of last May. "Mr. Shilling has sent us specimens of his New Early Grotto Pea, which were gathered on the 20th inst. He states that these were produced from seed sown in the open ground on the 28th of last November. Judging from the specimens sent, this is a fine, large, good-looking Pea, and will, no doubt, be found to be a very useful early variety."

To the Market Gardener they will be found invaluable. Price 1*s*. 6*d*. per quart, 10*s*. per peck.

SHILLING'S QUEEN CABBAGE, which gave such general satisfaction last year, as the best early variety grown. Having saved a considerable quantity of seed this summer, it is offered on the following advantageous terms:—1*s*. 6*d*. per oz., 10*s*. per lb.

Agents—Messrs. Field and Child, 149, Lower Thames-street; Messrs. J. and W. Noble, 152, Fleet street; Mr. J. Keenan, 4, Great Russell-street, Covent Garden; Messrs. Hurst and M'Mullen, 6, Leadenhall street, London.

Northwarborough Nursery, Odiham, Hants.

KNAP HILL AND BAGSHOT NURSERIES.

NOTICE.—The Business of these Nurseries, since the death of the late Michael Waterer, carried on, in the name of H. and J. WATERER, is by mutual agreement divided. The KNAP HILL NURSERY will in future be carried on by HOSEA WATERER, and that at BAGSHOT by JOHN WATERER. It will, therefore, be of importance, to prevent confusion, that correspondents be particular in the address and direct letters intended for the Knap Hill Nursery, to Hosea Waterer, Knap Hill, near Bagshot; and those for the Bagshot Nursery, John Waterer, Nurseryman, Bagshot, Surrey.—November 16.

J. T. WILLMER, Sen., having purchased the Stock of those beautiful Fuchsias noticed in the *Gardeners' Chronicle* of May 18 and June 1, under the initials of "T. L. H." Nos. 1, 2, 3, 4, 6, 10, 11, 13, and described as being a fine set of flowers, large, the upper petals in fine proportion, the side petals generally meeting above the eye, J. T. W. has a few sets of the eight sorts, with their names, to dispose of; the price for each set is 30*s*. Early application is requisite, to insure them. This Advertisement will not be repeated.

Sunbury, Middlesex, Nov. 13, 1844.

NURSERY LARCH.

COWAN AND CO., Nurserymen, Glasgow, have on hand a large quantity of well grown transplanted LARCH, 2 and 3 feet high, which they will sell at a low price, as they must be removed this season. All sorts of Forest-trees, seedling and transplanted, grown extensively, and offered at very moderate prices.

S. GIRLING begs to refer the Readers of the *Gardeners' Chronicle* to his Advertisement of PETUNIAS, SEEDLING VERBENAS, DAHLIAS, &c., of the 12th October.

Dancecroft Nursery, Stowmarket, Suffolk.

FASTOLFF RASPBERRY.

J. T. WILLMER, Sen., respectfully informs his Friends and the Public that he has a few hundreds of the above Superb RASPBERRY, warranted to be the genuine kind. 100 Canes, 40*s*.; 50 Canes, 20*s*.; and 25 Canes, 12*s*., including mat and packing.

J. T. W. has likewise a superb collection of CARNATIONS, PICOTEES, PINKS, and AURICULAS on sale, Catalogues of which may be had by post-paid application.

12 pairs first-rate Carnations	£2	0	0
12 ,, ,, Picotees	2	0	0
12 ,, ,, Pinks	0	12	0
12 plants of fine named Auriculas, including boat and packing	1	0	0

Sunbury, Middlesex, Nov. 13.

FASTOLFF RASPBERRY.

JOHN BELL begs to refer the readers of the *Gardeners' Chronicle* to his Advertisement last week of the above Raspberry, which may also be had true of the following Nurserymen:—Mr. W. Catleugh, Hans-place, Chelsea; Mr. W. Moore, Dereham; Mr. Bishop, Wacton; and Mr. J. W. Nutting, Seedsman, 46, Cheapside, London.

Messrs. Youell and Co., of the Yarmouth Nursery, having stated in their Advertisement of last week that the Raspberry they call the Fastolff can only be had true of them or their Agents, J. Bell feels bound, in justice to himself and other Nurserymen whom he serves with the above, to state that he has had his Canes the last three seasons from the same persons Youell and Co. have had theirs from; and that the above Raspberry is not so exclusive as Messrs. Y. and Co. wish the public to believe, as it is grown in almost every cottage and gentleman's garden at Burlingham, Lingwood, Acle, Rollesby, Ormesby, Hemsby, Filby, and all the adjoining parishes in that part of Norfolk; Ormesby and Filby being the two parishes from which Youell and Co., and myself, have had nearly all the stock. J. B. believes the Raspberry first originated in the garden of W. Jary, Esq., Burlingham, from which gentleman's garden J. Bell's first canes were procured. The Raspberry is generally known about these parts as the Filby Seedling.

Bracondale Horticultural Establishment, Norwich.

THE FILBY, or FASTOLFF RASPBERRY.—At the request of some gentlemen living in the neighbourhood of Yarmouth, T. RIVERS begs to submit the history of this really excellent Raspberry to the public. In the year 1814 Colonel Lucas, of Filby, a place lying between Norwich and Yarmouth, discovered a Raspberry plant growing under an old Laurel hedge in his garden. His attention was drawn to it, and he soon found it to be a superior and delicious variety, so that in a short time every other sort was ejected from his garden, and this alone cultivated. It was not, however, till 1824 that he allowed his gardener to part with it, who then gave canes to his neighbours, and by this means it got to be cultivated in Caistor, Ormsby, and, in fact, in all the neighbourhood, under the name of the Filby Raspberry, to the exclusion of all other sorts. It has latterly often been called the Caistor Raspberry, from the Market Gardeners growing it in that parish. In Caistor is an old castle in ruins, that formerly belonged to the Fastolff family: the latter name was given to the variety by Youell and Co., when they first began to sell the canes. The fruit upon which Dr. Lindley pronounced his opinion was gathered in the Filby garden, now the property of the Rev. G. Lucas, who authorises and permits the publication of the above facts; and has also permitted his Gardener to supply the Canes after this date to T. RIVERS only.

Canes are sold at 30*s*. per 100, or 6*s*. per score, carriage paid to London. Charge for package, for small parcels, 6*d*., for large do., 1*s*. to 1*s*. 6*d*. Orders to any amount can be executed. The Trade price will be given on application.

Sawbridgeworth, Herts, Nov. 12, 1844.

TULIPS, HYACINTHS, RANUNCULUSES, ANEMONES, GERANIUMS, AURICULAS, CARNATIONS, and LILIUM LANCIFOLIUM.

H. GROOM, Clapham Rise, near London (removed from Walworth), by Appointment Florist to Her Majesty the Queen, and to His Majesty the King of Saxony, begs to recommend to the attention of the Nobility, Gentry, and Public his extensive assortment of the above Flowers, which, from the success he has had in their cultivation, he can offer at very moderate prices. He particularly wishes to call attention to the highly-flattering remarks on his Exhibitions of Tulips and Lilium lancifolium this season, in the various papers. He is also desirous of reminding the Nobility, Gentry, and Amateurs, who may wish to add to their collections or ornament their parterres with these beautiful flowers, that this is the best season to make a selection. The varieties of the splendid Lilium lancifolium are particularly adapted for parterres, as, besides being quite hardy, they flower at a time when the Nobility and Gentry are at their country seats, and when flowers are so much wanted. They only require to be known to be universally cultivated. Catalogues can be forwarded by post on application. Foreign orders executed.

BAGSHOT NURSERY, SURREY.

JOHN WATERER begs to call the attention of the Nobility, Gentry, and Public, to his unlimited collection of AMERICAN PLANTS, which are this season unusually well set with bloom buds, particularly those for forcing, comprising,—Rhododendrons, Kalmias, Azaleas, Andromedas, Ledums, Daphne cneorum, &c. Also those of larger sizes, among which may be had Rhododendron Catawbiense, and many other fine varieties; Kalmia latifolia, Magnolias, of sorts; Azalea coccinea major, and aurantia, &c., &c., from 3 to 6 feet, which are fine objects for single specimens or borders, being bushy to the ground. J. W. begs to recommend his unrivalled Stock of Cedars of Lebanon, 18 inches to 4 feet; also about 200, 4 to 9 feet, bushy to the ground, very handsome for Lawns; the whole of them warranted to move safely. Also about 6000 Spanish Chestnuts, 1 to 6 feet; 50,000 Birch, 3 to 4 feet; the whole of which may be had at moderate prices. N.B.—Planting done by contract.

Nursery, Bagshot, Surrey, 34 miles from Farnborough Station, South Western Railway.

TO THE PLANTERS OF ENGLAND.—TRUE HIGHLAND PINE.

JAMES GRIGOR, Nurseryman, Norwich, begs to remind such of the Planters of England as are anxious to enhance the beauty and value of their estates, that he is now sending out plants of this recently introduced and very desirable timber-tree, at the undermentioned prices:—

Single plants, strong and well rooted	6*d*. each.
Strong plants, 20 inches high	5*s*. per 100.
Do. 18 ,,	30*s*. per 1000.
Smaller-sized plants	from 10*s*. to 20*s*. ,,

For introducing this tree Messrs. Gregor, of Elgin and Forres, were awarded several premiums by the Highland and Agricultural Society of Scotland, where it is rapidly superseding the common Pine. In its old age it assumes in a great measure the darksome grandeur of the Cedar of Lebanon, and is therefore invaluable for planting in masses throughout the more prominent parts of distant landscapes. Sir Walter Scott describes it as presenting much of "the bold and contorted figure of the Oak;" and the *Quarterly Review* recommends it as an acquisition to churchyards and cemeteries. It is highly esteemed for all economical purposes, on account of the hardness and durability of its wood.

N.B.—J. G. has for the present disposed of all his potted plants; but as the others have excellent roots, there is no risk in removing them. A supply in pots will be ready in the course of next month.

CEDRUS DEODARA, raised from seeds in the open ground, 10*s*. each. Araucaria imbricata, Pinus excelsa, &c. &c. on reasonable terms.

TO PEAR-GROWERS.

RENÉ LANGELIER, Nurseryman and Florist, CLARENDON NURSERY, ST. HELIER, JERSEY,

Begs leave to draw the attention of Pear-growers to his new PEAR, named "LANGELIER'S BEURRÉ" of first-rate merit; perfectly melting ripe in January; shape of Napoleon, but larger in size; standard, tree very vigorous; one of the best flavoured Pears known, otherwise it would not be recommended by R. L., as his motive for advertising it is not for the sake of publishing, but for the good of the public in general, to whom he is happy to have the opportunity of rendering himself useful; of which "Von Mon Leon Le Clerc" will be a sufficient guarantee, having proved itself as it was represented, and given universal satisfaction. The trees of this Superb New Beurré are small and limited in number, and the price will be 21*s*.; if 6 trees are ordered, 7 will be sent; no discount will be allowed to the trade, and to the trade only will 8 plants be sent for 6; the number is very limited. R. L. also takes this opportunity to state that to this day numbers of "Von Mon Leon Le Clerc" remain unpaid for, consequently none will be sent to unknown correspondents, except for ready cash, or post office order.

As this is the season for planting, R. L. wishes to draw the attention of the public to his acknowledged unrivalled Collection, of which a List may be had by pre-paid letter, and begs to state that nothing is sent from his Establishment except proved fruit, unless requested. R. L. also wishes to obtain attention to a small quantity of EVERGREEN OAKS, among which will be found a great variety; they are fine and healthy, 2 years old, about 12 inches to 2½ feet high, fit for planting or potting, price 20*s*. per 100. Also, fine KIDNEY POTATOES, superior in flavour and produce to the Ash-leaf; the sample, extra fine, 5*s*. 6*d*. for 24lbs. weight, as not less than that quantity will be sent.

RICH LEAF-MOULD and PEAT-EARTH.—Several acres of valuable Peat-earth and Leaf mould of a rich quality, to be disposed of. Gentlemen and Nurserymen engaged in the Cultivation of Heaths and American Plants will find the above articles of a very superior kind. They will also be found of great value as dressings upon strong lands.—The Estate is within one mile of the Thames, convenient for water carriage. For full particulars apply to Mr. Lawrence, Corn Chandler and Seedsman, No. 18, Piccadilly.

NURSERY STOCK.

RICHARD MITTON, Nurseryman, Pontefract, being about to clear off five Acres of Nursery Stock, consisting of Forest and Fruit-trees, Evergreen and Flowering Shrubs, &c., begs to offer the same at unusually low prices. Particulars may be had on application.—Pontefract, Nov. 16.

A SPLENDID NEW AZALEA AND FUCHSIA.

WM. PAWLEY, White Hart Hotel, Bromley, Kent, has now ready for delivery a beautiful and distinct variety of Azalea, named "Carminator," that gained first prize at the Regent's Park Exhibition, April 30th, 1841; a fine large flower, very dark, good habit, and a free bloomer: established plants, 21*s*. each.

Fuchsia Cassandra.—This beautiful and distinct variety is now ready, at 10*s*. 6*d*. per plant; for particulars, see Professor Lindley's opinion in *Gardeners' Chronicle* under the initials "M. C.," Sept. 7, p. 608.

N.B.—The usual discount to the Trade, and a remittance from unknown correspondents.

EXHIBITION OF CHRYSANTHEMUMS.

CHANDLER AND SONS, Nurserymen, Vauxhall, London, beg to state that their Collection of this beautiful autumnal Flower is now in bloom, and will continue for the next two or three weeks.

C. and Sons are now sending out healthy young plants of Double CAMELLIAS of sorts, with flower-buds, at 30*s*. per dozen, larger plants, 42*s*. per dozen; and young plants of the newer sorts, at 60*s*. per dozen. Package included in the above prices.

EDWARD BECK informs the Public that in consequence of the greatly increased demand for his SLATE TUBS, he is enabled to reduce the price of the following sizes about 10 per cent. He regrets the too frequent delay which has occurred in the execution of orders. This he hopes to avoid in future by keeping a supply on hand.

Present Prices for Cash or Post-office order:—

14 inches	11*s*.	0*d*.	20 inches	22*s*	6*d*.
15 inches	12	6	22 inches	25	0
16 inches	16	0	24 inches	34	0
18 inches	19	0			

Slate Works, Isleworth, Middlesex.

CARNATIONS AND PICOTEES.

JOHN DICKSON, Acre-lane, Brixton, Surrey, has prepared for the growers of these splendid flowers a Catalogue, containing them to choice of their qualities, with the prices annexed, which may now be had at the Nursery, and of Messrs. Warner & Warner, Cornhill, London.

THE TRUE PASTOLFF RASPBERRY.

GREAT YARMOUTH NURSERY. NORFOLK. 1844.

PATRONISED BY HER MOST GRACIOUS MAJESTY THE QUEEN, HIS GRACE THE DUKE OF RUTLAND, HIS GRACE THE DUKE OF MARLBOROUGH, THE EARL OF HARRINGTON, THE EARL OF LIVERPOOL, THE LORD BISHOP OF LONDON, LORD VISCOUNT LORTON, LORD SONDES, &c. &c.; as well as by the HORTICULTURAL SOCIETY OF LONDON.

YOUELL AND CO. beg to announce they are again able to supply fine canes of the above truly excellent variety, unequalled for the size of its Fruit and richness of flavour; prices as follow:—

Packages containing 100 Canes	.	£2	0 0
Ditto " 50 "	.	1	1 0
Ditto " 25 "	.	0	12 0

For particulars of the above, see YOUELL & Co.'s Advertisement of Nov. 9th.

YOUELL and Co. feel it due to themselves to state that a spurious kind was offered for sale by other parties last season, under the title of "Pastoff Raspberry," the same having no pretensions to the genuine variety; and to obviate a repetition of the like they have appointed the following Nurserymen and Seedsmen as their Agents for the sale of it, at whose establishments may be seen growings of the Fruit:—Bury St. Edmunds—Mr. R. Pettit; Canterbury—Mr. W. Masters; Carlisle—Messrs. Little and Ballantyne; Chichester—Messrs. Newman and Co.; Cheadle, near Leek, Staffordshire—Mr. F. Fox; Cork—Messrs. Hayecraft; Doncaster—Mrs. Milan, Seed-shop; Dundee—Messrs. Urquhart and Son; Durham—Messrs. Hancock and Sons; Edinburgh—Messrs. Peter Lawson and Son; Feltham—Messrs. Whitley and Orsborn; Glasgow—Messrs. Reynolds and Co.; Hadlington—Mr. T. Dods; Halifax—Mr. W. Throp; Jersey—Mr. B. Saunders; Leeds—Messrs. Ely and Son, Rothwell Haigh; London—Messrs. Flanagan and Son, No. 9, Mansion House-street, and Messrs. Noble, No. 152, Fleet-street; Liverpool—Mr. James Cuthbert, 12, Clayton-square; Manchester—Mr. H. D. Cormack; Nottingham—Mr. J. F. Wood, the Coppice; Peterborough—Mr. John White; Penzance—Mr. J. Fox; Plymouth—Mr. W. E. Rendle; Shef field—Messrs. Fisher, Holmes, and Co.; Southampton—Mr. James Jupiter; Stafford—Mr. J. Sandy; Torquay—Mr. J. Morgan; Wakefield—Mr. W. Barratt; Waterford—Messrs. Fennessy and Son; Wellingham, Kent—Mr. J. Cattell; Wexford—Mr. James Harper; York—Messrs. T. and J. Backhouse.

YOUELL'S CELEBRATED TOBOLSK RHUBARB, the earliest sort known, fine roots, fit for forcing, 12s. per dozen. For Particulars, see their Advertisement of Nov. 2.

Finest Imported DUTCH HYACINTHS, 6s., 12s., and 18s. per doz.; for Particulars of which, together with the Extensive and Select Collection of CARNATIONS, PICOTEES, and PINKS, see their Advertisement of Nov. 9.

Great Yarmouth Nursery, Nov. 13.

NEW AND SPLENDID RHODODENDRONS.

RHODODENDRON WILLIAMSONII. — This magnificent variety was forwarded for the opinion of Dr. Lindley and also of Mr. Glenny. Dr. Lindley (see *Gardeners' Chronicle* for May, 1844)—"*G. B. S.*—Your seedling makes a handsome and showy variety for the garden; the heads of the flowers are large, compact, rich in colour, and the foliage is very handsome." Mr. Glenny (see *Gardeners' Gazette* for May, 1844—"*G. B. S.*—If hardy, a very great acquisition; size very large, bright rose, well spotted, and if bloomed in the open ground, a valuable addition to our hardy plants, for the foliage is as perfect as the flower."

RHODODENDRON INVICTUM.—A very dazzling deep rosy crimson, very dark spots, a most distinct and superb variety, and blooms later than most of the Hybrids, and quite hardy. The above two splendid hardy Rhododendrons now offered to the public were raised by Mr. Williamson, the Curator of the Sheffield Botanic Garden, where Invictum has bloomed for several years, and has been the admiration of all who have seen it. Price for the two, 21s.

Apply to F. Godwin, Nursery and Seedsman, Sheffield; W. and A. Godwin, Market Drayton; or Messrs. Warner and Warner, 28, Cornhill, London, where paintings of the above may be seen.

SUPERB DWARF ROSES.

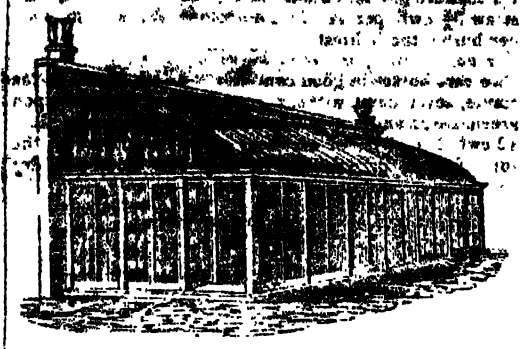
F. GODWIN, having a very large stock of Dwarf Roses, including the most approved varieties of the Hybrid China, Gallica, Provence, Damask, &c., is offering them at the following reduced scale of prices:—

100 selected sorts, in 50 named varieties	.	.	.	25s.
50 " do. 25 "	.	.	.	15s.
24 " do. 12 "	.	.	.	8s.

The above are strong, healthy plants.

Sheffield, Nov. 12, 1844.

HOT WATER FOR BOTTOM-HEAT



J. WEEKS AND DAY, Architects, &c., Gloucester Place, King's Road, Chelsea, HORTICULTURAL BUILDERS, and Hot-water Apparatus Manufacturers, invite the attention of Horticulturists to their Improved Plan of Bottom Heat, now becoming so universally adopted.

From the extensive Practice they have been honoured with for so many years in designing and building CONSERVATORIES, GREENHOUSES, HOTHOUSES, PITS, &c. &c., and erecting their HOT-WATER APPARATUS to every description of Buildings to which heat is applicable, J. Weeks and Day have the greatest confidence in recommending their BOILERS as the most efficient of any yet invented, their largest being capable of heating a range of forcing Houses 200 feet in length, with a comparatively small quantity of fuel, and only requiring attention once in 10 hours. To be seen in use at most of the London Nurseries, also at their Manufactory; and a variety of Horticultural Erections, Models, Plans, &c. &c.

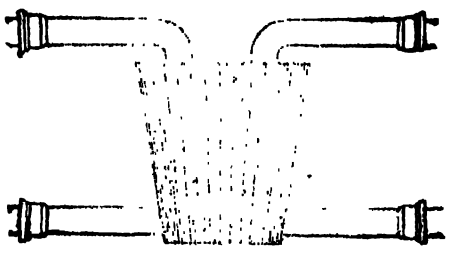
DUTCH HYACINTHS for forcing, Single and Double at 4s. per dozen; also Narcissi, Crocuses, Tulips, Irises, Jonquils, Anemones, Ranunculuses; priced Catalogues of which will be forwarded per post, from Arthur Corbett's Italian and Foreign Warehouse, 18, Pall Mall.

Double Italian Tuberoses should be potted in the first week of next month.

COTTAM AND HALLEN, Engineers, &c., Nos. 2, Wellington-street, Blackfriars-road, London, and at Cornwall-road, Lambeth.

HOTHOUSES, CONSERVATORIES, &c., made upon the most improved principle, either of iron or of iron and wood combined, which can be fixed complete in any part of the Kingdom, at very low prices.

HOT-WATER APPARATUS for heating Hothouses, Conservatories, and Greenhouses; Churches, Public or Private Buildings, &c., with Cottam's Patent or Rogers's Boilers. After 15 years' experience, and having fixed upwards of 3000 Apparatus for the above-mentioned purposes, and by various improvements which they have made during that time, C. and H. can with confidence undertake the erection of similar Apparatus upon the most extensive scale.



Materials may be had for those who wish to fix their own Apparatus.

THE TANK SYSTEM on an improved principle, that will heat the house at the same time, without pipes.

IRON HURDLES, best Wire for Strained Fencing, Ornamental Iron and Wire-work, Garden Chairs, &c., &c., and every description of Implement for Agricultural and Horticultural Purposes.

Show Rooms at their Manufactory, 2, Winsley-street, Oxford-street, where a large assortment of the above can be seen.

BURBIDGE AND HEALY'S NEW BOILER and FURNACE for HORTICULTURAL PURPOSES.
Registered under 6 & 7 Vict., Cap. 65.
No. 130, FLEET STREET, LONDON.

Burbidge and Healy respectfully inform the Horticultural Public that they have constantly on hand an extensive assortment of their new Boiler and Furnace Doors. In very numerous cases where they have been fixed, they have the highest testimonials of their complete success: for the further assurance of those who may require this apparatus, Burbidge and Healy refer them to the Horticultural Society's Gardens, Chiswick, also to Mr. Glendinning, Garden Architect, &c. &c., Chiswick Nursery, in the same neighbourhood, where the apparatus may be seen in successful operation, in connection with their new Tanks. The following are the present prices:—

Plain Boiler.	Patent Door and Frames.	Fire-bars & Dead Plate.	Flue Door.	Damper.	Will heat of Pipe.	Forcing Pit, Length by feet.
In.	£ s.	s.	s. d.	s. d.	s. d.	
10	1 5	20	7 6	6 2	6	30 feet.	12 to 20
Ribbed Boiler.						
10	2 2	20	10 6	7 6 2	6	50 to 70 ft. 4 in.	Under 25 to 40
12	2 15	30	12 0	7 6 3	6	80 to 125 feet.	40 to 65
14	3 10	35	17 5	9 6 4	6	150 to 250 feet.	65 to 100
18	5 5	42	25 0	8 6 5	6	300 to 400 feet.	Warm a grapery 35ft. long, and a pit 50ft.
24	8 15	50	35 0	8 6 7	6	600 to 800 feet.	

If 3 inch pipe be used, one third more. If 2-inch pipe, as much more.

The above quantities are rough estimates, which may be varied by enlarging or contracting the fire, or by regulating the fire door. It is possible to heat a much larger quantity of pipe with the boiler, but it would be done at great loss of fuel. The above proportions can be generally relied on as a near approximation to what is correct.

WIRE WORK, HOT-WATER APPARATUS, GREEN-HOUSES, &c.

ST. THOMAS BAKER, MANOR-HOUSE, MANOR-PLACE, KING'S ROAD, CHELSEA, Manufacturer of INVISIBLE WIRE-FENCE, to resist Grazing Stock, and rendered Rabbit-proof. WIRE-WORK in Trainers, Arches for Walks, Bordering, Flower Stands, Pheasantries, &c. HORTICULTURAL BUILDINGS, Green and Hothouses, Conservatories, &c. The same heated by HOT-WATER APPARATUS, on improved and economical principles.

Parties waited on in Town or Country, and Drawings and Estimates free. Work for the Trade as usual.

Ward's Cases, or Domestic Greenhouses.

CONICAL BOILERS.—The Boilers invented by Mr. James Weeks, and made only by Messrs. Green, of Lambeth, and many of the Nobility and Gentry in the Country, have given the greatest satisfaction, and may be seen in operation at Messrs. Chandler's, Vauxhall; Loddiges', Hackney; Henderson's, Pineapple-place, Edgware-road; Rollinson's, Tooting; Penny's, Plymouth; The Horticultural Society's Gardens, Chiswick; and in the Gardens of the Royal Botanical Society, Regent's-park.

HOT-WATER APPARATUS FOR HEATING HORTICULTURAL BUILDINGS, DWELLING-HOUSES, CHURCHES, and MANUFACTORIES, upon improved principles, and at very moderate charges, erected by DANIEL and EDWARD BAILEY, 272, HOLBORN.

D. and E. Bailey having devoted much time to the consideration of this subject, and had much experience in the erection of apparatus for the above-mentioned purposes, have, by improvements suggested in their practice, rendered their mode of heating not only very efficient, but very simple, and have combined durability in the principal portions in its charge. They have erected apparatus in England, Scotland, and Ireland, for many noblemen and gentlemen, and have had the honour to be employed by the Horticultural Society of London, in executing the works of their splendid Conservatory, lately erected at Chiswick. D. and E. Bailey have also constructed, under the inspection of Horticultural Buildings and Stoves, and invite noblemen, gentlemen, and the public to an inspection of their various drawings and models, at 272, Holborn, where they have the opportunity of exhibiting amongst other metal works, an extremely complete and convenient kitchen apparatus, on range, adapted for the continued supply of hot water, and an arrangement of the oven more complete than has hitherto been brought before the public.

D. and E. Bailey were the first to introduce metallic curvilinear houses to horticulturists, and have built in the Conservatory attached to the Pantheon as one of their works, besides many others in this country and on the Continent.

D. and E. Bailey have prepared a quantity of the Galvanic Plant Protectors, with the new safety valve and medicine delivery; they beg to introduce to public notice a new Trough Pipe, for Orchidaceous or other Houses where vapour is constantly, or at intervals required, and which may be seen at their Manufactory.

IMPORTANT TO AGRICULTURISTS, &c.

ANALYSES of SOILS, MANURES, and all AGRICULTURAL PRODUCTS are conducted by Messrs. Mitchell and Field (late Mr. Mitchell), Analytical Chemists, with the view of ascertaining whether the Soil in which it is proposed to grow any particular crops contains all that is necessary to produce a luxuriant vegetation; also to estimate the relative value and purity of Manures, and the comparative worth of Farm Produce in general. Instructions contracted in Agricultural Chemistry. The course will comprehend the Elements of Analysis.—No. 5, Hawley-road, Kentish Town.

GUANO for SALE, in Bags of 1 cwt. each, just landed, with a succession of cargoes to arrive.—Successive years' experience has unquestionably proved that Genuine Guano is the simplest, cheapest, and best Manure within the reach of the Agriculturist. The only reasonable anxiety which now remains is to procure the Guano unadulterated, and to obtain such practical directions for using the Manure as shall fully develop its productive powers. To secure to buyers these indispensable requisites, with each purchase will be given a warranted chemical analysis of quality, and also a copy of the recently-published Pamphlet, "Practical Instructions for using Guano as a Manure, illustrated by Practical Results."

Large parcels will be delivered direct from the ship or waterside premises, smaller quantities may be had at the warehouses, 24 and 25, Billiter-street, and delivered within any reasonable distance at a trifling additional cost. Apply to James Clark, 24, Billiter-street, Fenchurch-street, London.

UNRESERVED SALE OF NURSERY STOCK.

MESSRS. PROTHEROE AND MORRIS beg to announce that the Sale of the VALUABLE NURSERY STOCK, at the Key Field Nursery, St. Albans, Herts, will commence on Monday, November, 18th, 1844, and two following days, at 11 o'clock each day.—American Nursery, Leytonstone.

TO NURSERYMEN, SEEDSMEN, AND OTHERS.
LAVENDER HILL NURSERY, WANDSWORTH ROAD.
UNRESERVED SALE OF EXTENSIVE NURSERY STOCK.

MESSRS. PROTHEROE AND MORRIS are instructed by the Executors of the late Mr. Pamplin, to sell by Public Auction on the premises, Lavender Hill Nursery, Wandsworth-road, near London, on Monday, Dec. 2d, and following days, at 11 o'clock on each day, the whole of the EXTENSIVE and VALUABLE NURSERY STOCK, comprising a large quantity of the finest Hardy Evergreens of all sizes (which remove particularly well out of this ground); Fruit and Forest Trees, Shrubs and American Plants; Hardy Herbaceous Plants; large and small Camellias; a very capital collection of Ferns, some of which are of extreme rarity; Garden Frames and Lights; Shop Fixtures and general Fittings of a Seedshop and Counting-house; Stock of Seeds of the present Harvest; Garden Implements, including useful Carts, Barrows, &c.; several thousand yards of Box Edging; about 200 Pollard Willows with their tops and tops; Evergreen and other Hedges; also some growing Crops, as Mangold Wurzel and Turnips; together with many useful articles.

The whole will be sold without the least reserve, the premises having been disposed of for other purposes, and must be cleared before Christmas.

Catalogues will be ready one week prior to the Sale, and may be had on the premises; at most of the Seedshops in London; at No. 43, Frith-street, Soho; and of the Auctioneers, Leytonstone, Essex.

SIX THOUSAND MOSS ROSES.

MR. JOHN KING begs to give notice that he is Instructed to Sell by Auction, on the Premises, Victoria Park, on the 19th November, 1844, at 12 o'clock precisely, by order of Mr. Carter, of Grove Street, Hackney, about 6000 MOSS ROSES, Fruit Trees, a large quantity of Flower Plants, Cucumber Boxes and Lights, Tools, Seeds, Hedges, &c. To be Viewed till the Sale. Catalogues had on the Premises; Three Colts, Grove Street; of Mr. Clark, Seedsman, Bishopsgate Street; and of the Auctioneer, Hackney Road.

TO MARKET GARDENERS, GENTLEMEN'S GARDENERS, AND OTHERS.

TO BE SOLD, a Bargain, within one hour's drive of Covent Garden Market, THE LEASE OF AN EIGHT-ROOMED HOUSE, EXCELLENT OUTBUILDINGS, AND FOUR ACRES OF CAPITAL MARKET-GARDEN GROUND, covered with the choicest Fruit Trees in full bearing. Also, from 3000 to 6000 feet of Glass, that has been erected within the last four years, and heated by hot water. Likewise the Stock and Crops, which consists of upwards of 400 Fruiting Pine plants, nearly two succession ditto, several thousand Strawberry plants in pots for forcing, upwards of a Thousand Chillies, several thousand empty pots, tools, leaded cisterns, with every other requisite for carrying on a most profitable Trade. There are 36 years of the Lease unexpired; Rent, 50l. per annum. For further particulars apply, personally or by letter, to J. D., Mrs. Lowe's, Grocer, Bishopsgate; Middleton.

FARM.—Wanted to Purchase, a FARM of 200l. to 400l. a year rental, it must be south of the river Thames.—Address, by letter, stating size, situation, rent, and price, to E., *Gardeners' Chronicle* Office, 7, Upper Wellington-street, Covent-garden, London.

FOR SALE, an INDIAN BULL, COW, and CALF, and the Cow, which is only thirty-six inches high, again forward in calf.—Apply to Mr. Gulley, Langford Budville, Wellington, Somerset.

to ascertain the best mode of its equal distribution over the soil, he next caused it to be mixed with water to the consistence of cream. This he had passed through a fine riddle; a fresh quantity of water was mixed with the refuse, and in this manner the whole of the guano was separated from the bones, feathers, skins, and grit. A given weight of the guano thus prepared was mixed with a given number of bushels of dry mould of good tilth, or both mixed together, and when the mass was made it was just dry enough to pass through a screen or iron riddle, and to admit of being sown immediately before or after the prepared soil. In mixing up the guano with water, he used a few pounds of powdered gypsum as a fixer, according to the common phrase, and he urged the importance of such an addition, whether the guano was applied as he used it, or in its original state. He was satisfied that, when he considered the influence of the long continued dry weather during the early part of the season, he would have had little or no crop on his dry soil, but for the invigorating and powerful influence of the guano; and he had this year a better green and corn crop than he had ever had before.—Mr. Fraser, of Reelig, kindly stated that he had been in the habit of applying three cwt. of guano per acre, sowed with the crop, and had found it succeed admirably. In his opinion and experience the best way for Turnips was to sow the guano broadcast (after the land is clean and in order for drilling), plough, harrow well in, and drill up—the whole guano will be then in the raised drills, but intimately mixed with the soil, so as to furnish food in the best manner to the young plant, without burning the seed. As to white crops, he thought that either the whole or part of what is given per acre should be sown broadcast, and harrowed in, when the seed sown and harrowed in, so that the whole should be mixed as before with the soil. When a part is reserved it should be sown in spring, when the plant (Wheat) begins to look sickly, when the guano will start it afresh. A friend from London says, that it has been recommended, when sowing guano with white crops, to add from ¼ to ½ cwt. of nitrate of soda, which brings away the plant finely.

Witham.—At the late meeting of this Agricultural Society the President read an account of the following experiment with manure:—Much has been said respecting the management of farm-yard manure, some contending that rain or water injures the quality of such manure, and renders it worthless. Others believe that such manure cannot be made without a considerable portion of water, as dry muck will mould, and lose all its fertilising qualities. The following experiment was made this last summer, 1844:—On the 15th of November, 1843, 10 Scots were put loose in stalls 12 feet square, fed with Bean meal, cut hay, malt coombs, and oil-cake. Each bullock foddered or littered with one truss of good wheat straw per day, 30 lb. per truss, carefully weighed; cleaned out once a month; no urine escaped, all was absorbed by the daily large quantity of straw foddered. On the 13th of January, 1844, five stalls were cleaned out, and the manure weighed the same day, carefully laid by itself, and covered nine inches thick with earth—no evaporation escaped; stirred over three times and watered each time, as the manure was disposed to mould very much. On the 4th of April weighed again, and carted upon the land for Oats, not very rotten; the carts were filled exactly 2 tons weight, and laid upon one quarter of an acre. On the same day, 13th of January, the other five stalls were cleaned out, and laid upon dry ground, all exposed to the weather, from the 13th of January to the 4th of April, weighed and managed exactly as the other five stalls, stirred on the same days, watered when stirred; what drained from it was thrown upon the heap of manure. Exactly 3 tons laid upon the same quantity of land. The whole threshed directly out of the field, 24th August. One quarter of an acre of Oats produced, from the manure closely covered up, 18 bushels 1 peck, weighed 38 lbs. per bushel. Straw 5 cwt. 1 qr. 18 lbs. One quarter of an acre, not covered up, produced 17 bushels 1 peck; weighed 39 lbs. per bushel. Straw 5 cwt. 1 qr. 6 lbs. In tabular form they will stand thus:—

	qrs.	bsh.
Covered manure, produce	9	1
Not covered	9	5
In favour of covered manure	0	4

	cwt.	qrs.	lbs.
Produce of straw, per acre, covered	21	3	10
Ditto not covered	21	1	16
In favour of covered manure	0	2	0

On the same day, one quarter of an acre was manured with 1 cwt. of guano, and produced 19 bushels 37½ lbs. per bushel. Straw 2 cwt. 2 lbs. Oats, guano-manured, equal to Quite 4 bush. per acre; straw 2 cwt. 2 qrs. per acre. The guano-manured exceeded 3 bush. of Oats per acre more than the covered muck.—N.B. Guano was sown on Wheat, Barley, Oats, and Carraway, upon another farm, a different soil, subsoil clay; no benefit was observed. The drought continued a long time.

The following paper was then read on *Sowing Wheat.*—August, 1843, one quarter of an acre of a very gravelly soil—in a hot summer producing but little—was, after Peas, ploughed four times in the same day with six horses, 15 inches deep; dibbled with Wheat in October, and produced at the rate of 6 bushels 3 pecks per acre more than the land by the side of it, ploughed in the usual way for Wheat 5 inches deep. Straw 3 cwt. per acre more than the adjoining land of the same measure and same soil. This same field is subject to Wire-grass in the autumn; in a few weeks it is thickly coated. One acre was hoed and burnt, costing 10s. per acre. One acre by the side of it ploughed with wheat quarter. All dibbled, no visible difference throughout the year either in produce or in cleanliness of the land during the summer of this autumn, 1844. One acre in the same field was folded 14 nights with 200 sheep, fed in the day-time on stubbles—no oil-cake or Corn. The other part of the field all manured, 10 tons of good muck per acre. The folded Wheat succeeded the manured Wheat 2 bushels 3 pecks per acre, and the straw 3½ cwt. per acre. The folded Wheat 1 lb. 4 ds. per bushel the lightest.

Experiment upon Horse-keeping.—June 24, 1841.—Two cart-horses in good condition were kept [illegible] the stable, seven days, without going [illegible] upon green Tares and Corn.—[illegible] days 12 cwt. 1 qr. 9 lb. of excellent [illegible] the top of the growth. [illegible] dry weather, no waste.

	cwt.	qrs.	lbs.
Also one peck of Oats per day per horse	1	1	12
3 bushels 3 pecks wheat straw	20	0	4
Also chaff	1	2	0
Corn and chaff	1	3	12
Tares	18	1	9
Two horses consumed in one week	14	0	19
One horse consumed in weight in 7 days	7	0	9

That is, 113 lbs. per day for one horse. Drank 6 gallons of water per horse per day. Two horses littered for 7 days, one truss of Wheat straw per day, 36 lbs. per truss.

	cwt.	qrs.	lbs.
From 252 lbs. of straw and the above food and water.—Weight of manure in its raw state at the end of the week	12	2	3
Monday, 5th of August.—Weighed the muck made from the green Tares after lying in a dry stable six weeks, stirred over four times, four pails of water (that is, 16 gallons) thrown upon it, as the dry muck required it every time to prevent its moulding. It was not very rotten; it was removed with a fork, no shovel used: weighed this day	5	1	10

N.B.—The stable was a sound old brick floor, with a gutter in it; a 10-gallon copper was placed at the fall of the gutter, and cemented carefully. No urine could escape. Only 21 quarts of urine in the seven days drained into the reservoir. *Second Experiment on Horse-keeping—with dry food.*—Monday, the 7th July, 1841.—Two cart-horses (not the same as before mentioned, but of the same size and condition) were kept in the same stable upon dry food, and not removed for seven days.

	cwt.	qrs.	lbs.
3 cwt. of excellent Clover hay consumed in the 7 days	3	0	7
1 peck of Oats per day per horse	1	1	0
Also chaff	0	2	4
Two horses consumed in one week	4	3	11
One horse consumed in weight in 7 days	2	1	19

That is, 39 lbs. per day for one horse upon dry food. Drank 12 gallons of water per day per horse.

	cwt.	qrs.	lbs.
Weight of manure in its raw state, from 252 lbs of straw, and food and water	10	1	2
The same, after being kept in the stable 6 weeks, stirred over 4 times, 4 pails of water each time (great difficulty in preventing its getting mouldy): it weighed	6	0	2
Decrease in weight	4	1	0
Only 13 quarts of urine drained from the dry food. Observe, manure made from green food, when in a proper state to be carted upon the land	5	1	10
Difference in weight in favour of green food	1	0	10

Notwithstanding this increase of weight in the green food, it is presumed the manure made from the dry food is of the most value.

The President then said, Mr. W. Hutley had put into his hands the following paper relative to experiments with Wheat drilled on the same description of land:—

Account of the Produce from different quantities of Wheat, drilled upon equal quantities of land.

No. 1. Drilled at the rate of 4 pecks per acre, rows 12 inches apart.

	qrs.	b.	pk.	pt.
Produce—Wheat, best	3	3	1	2
Seconds and tail	0	1	1	5
Total	3	4	2	7

Straw 12 cwt. 13 lb.

No. 2. Drilled at the rate of 6 pecks per acre, rows 6 inches apart.

Wheat, best	3	5	3	0
Seconds and tail	0	1	1	2½
Total	3	7	0	2½

Straw 15 cwt. 13 lb.

No. 3. Drilled at the rate of 9 pecks per acre, rows 6 inches apart.

Wheat, best	3	6	1	5
Seconds and tail	0	1	3	3
Total	4	0	0	8

Straw 18 cwt. 3 qr. 27 lb.

N.B.—No. 1 was about a week later in sowing than the other two pieces.

The President said, Professor Johnston told him that the other day he was in Hampshire, and there he found thin sowing answered very well.—Mr. H. Dixon said, Mr. R. Dixon had tested Lord Western's recommendation of 9-inch drilling against his own, which was six inches. He sowed at least two bushels and a half an acre, generally three; and there were 71 acres of land which in 12 years had grown 272 acres of Wheat, the average of the crops for those 12 years being pretty well 5½ qrs. per acre. This was from thick sowing. He was also a thick sower of Beans; he put on six or seven bushels of beans per acre; his average for the last 12 years was eight quarters (!) of Beans per acre.—The President asked if Mr. Wm. Hutley could give them an idea of the expense of burning and draining his land. The land was forked after the plough, and he saw there were 20 men to two ploughs, which must have been a considerable expense.—Mr. Hutley said, when he took his farm he thought no land was more out of condition; it was extremely poor, and was overrun with Thistles, Docks, and everything that can be pretended to good farming ought to try to eradicate. The first thing he set about was to take the water off it, which had cost him rather more than 2000*l.* on 160 acres, as he had made rather more than 1000 rods of drainage through it. At the time he took the land there were a vast number of Pollard-trees on it, and being fully convinced these were an injury to the farmer, and an impediment to good cultivation, he cut them down and drew them home. He then set about the tillage of the land with spirit. He forked 25 acres of it, ploughing five inches and forking ten, and keeping the subsoil at the top; that cost him 10*s.* an acre to plough, because the horses going upon the soft soil could not get over so much land; and the forking cost him 4*l.* 4*d.* an acre. He had 13 acres of the land so bad, and so soft in some places, that the cattle could hardly go upon it. After he had drained it, it cost 5*l.* or 6*l.* an acre to plough; then 4*l.* for burning; and he had now got as good a crop of Turnips on it as at any other part. The whole expense of bringing the land into this state will run 12*l.* to 15*l.* an acre; and with the year's rent for the 160 acres, it had cost him, without anything for stock, except horses, 2600*l.* He thought it was the duty of the landlord to take a tenant that was competent to employ labour and improve the soil. The next thing was to give them a lease and stimulate them to lay out their money. He had seen a vast deal of mismanagement, and a good deal of good management, but he never saw a man that could farm that had not got a lease, for he never saw him disposed to try. He would say to the landlords, "You cannot grow timber and corn too." They had a discussion on this subject at the Farmers' Club twelve months ago, and the conclusion they came to was that they should endeavour to get rid of the timber by offering the landlord 2*s.* an acre extra rent; he was sure it would be worth it; and he was sure if the landlord laid out that money in land, in the course of ten years it would produce more than all his timber was worth. Let them grow their timber where it ought to be grown—in woods. Looking around that neighbourhood they would find invariably that when individuals were without leases, and had timber on the estates, they had little in their pockets and nothing in their cupboards.—Mr. J. Beadel, in the course of his remarks on the state of Agriculture in Ireland, said, the system of cropping as he observed it would rather surprise them—they began with Potatoes; then they took Wheat; after Wheat they took four or five successions of Oats; and then they laid the land down to "rest," as they called it, but during the time land was thus at rest, he had seen upon it weeds, Docks, &c., taller and bigger round them he was himself. He walked over one field of this sort with the farmer, and he said to him, "What do you call this?" "Oh," said he, "that is at rest." "Rest! we should not call it rest in England, for we consider it draws the land as much to grow weeds as to grow corn."—This, it would appear, is an exaggerated picture of the most cultivated districts in Ireland.

Darlington.—The Members of this Club held their Monthly Meeting on Monday last, at the Offices of Mr. Thos. Dixon, Land Agent, their Secretary; the subject under discussion being The best Method of preserving Turnips through the Winter, and whether it is desirable to draw them from the Land, both as regards the preservation of the Turnips and keeping the Land in condition. The chairman introduced the subject, and during the course of the discussion he read an able communication on the subject from the pen of Mr. Davidson, a well-known correspondent of the Club. The members present were unanimous in opinion that in every case where Turnips are stored either in houses, in camps, or otherwise, in considerable quantities, it is desirable to pay attention to the manner in which the Turnips are prepared for storing. The top and roots ought to be taken off, together with as much dirt as possible, in order that the Turnips be stored clean; at the same time being careful in cutting off the tops and tails not to injure or wound the bulb or Turnip, as by that means, if wounded, its juices are exhausted and it is more liable to decay. With regard to storing or preserving the Globe or common White Turnip, it was only considered expedient so far as to have a regular supply always on hand, to serve the cattle in case of severe frost or wet weather, and on that account it becomes necessary to have three or four weeks' provision laid up beforehand, else it is generally found that White Turnips answer best and feed to most advantage when fresh drawn from the land; besides, when stored they do not generally keep well for any length of time, and in no case should they be stored later than the middle of December. With regard to Swedes and other hardy and late winter Turnips, the members were of opinion that it was in numerous cases advantageous to draw them from the land and store them, both as regards preserving the Turnips and keeping the land in condition and free from exhaustion. Swedish Turnips are of a hardy nature, and when healthy stand the winter frost well; but in very early spring, when vegetation takes place, both the Turnip and the land begin immediately to suffer, the bulb of the Turnip begins to turn into

woody fibre, and the roots begin to draw upon and exhaust the land without benefiting the Turnip; therefore, under these circumstances, it was considered desirable to take advantage of a fine dry season, not later than the commencement of February, and draw from the land and store, as far as practicable, all the later and hardy kind of Turnips for spring use. Where parties have not the advantage of sufficient Turnip houses and sheds for storing their Turnips, it was considered a good plan to pile them up between ranges of sackbags or bundles placed about four or five feet apart, and filled with straw. The Turnips then filled in to the height of four or five feet, and then thatched or covered over with straw in like way they keep pretty well. Upon dry land, where it may not be convenient in all cases to have the spring Turnips drawn from the land previous to vegetation taking place, a cheap method of putting a partial stop to vegetation was named by one of the members, which was as follows: —Go over the rows and pull all the Turnips nearly up by the roots, and then leave them in their former position; by this means vegetation is delayed, and yet the Turnip keeps pretty fresh. Another point of very considerable importance was also touched upon, viz., the carting Turnips off the land; it was considered that too much care could not be taken to have this done when the land was in a proper state, as in many instances, where the Turnips are carted off whilst the land is in a very wet state, there is no calculating the injury done to the land. The subject fixed for discussion at the November meeting is, The proper Time for Ploughing and preparing Land for Beans and other Crops.

Wrentham.—At the last monthly meeting, the subject before the Club was, The most eligible System of working Horses on a Farm, whether by yearly In-door Servants, or by Week-men. The peculiar province of a team-man was allowed to be one of much importance on a farm, and the present discussion was therefore not solely on the working of horses, but on the qualifications indispensable for such a post. On the score of economy the difference between hired servants and week-men was believed to be inconsiderable, although slightly in favour of the former. The question was therefore considered more as one of expediency, which could only be determined by reference to peculiarity of situation, or other local circumstances. Frequent changes being at all times undesirable, the advocates for week-men as horse-drivers were of opinion that when married men living contiguously were employed in that capacity, their services were likely to be more permanent, and consequently the interest in promoting their employers' welfare, being that of securing their own continuance, was greater. Yearly servants, on the contrary, were not usually to be depended upon beyond the expiration of their period of service; and as these men generally obtain an increased rate of wages, it is desirable on this head that the preference should be given to married men. On the other hand, it was believed that horses received better treatment when attended to by hired servants and single men, and it was also considered questionable whether the practice of entirely employing week-men, and particularly married men for this purpose, did not induce earlier or imprudent marriages, under the idea of obtaining better places, thus operating not unfrequently to the injury of a parish. In remote situations, in-door servants are decidedly to be preferred as a matter of convenience. It was also urged that the system of keeping hired servants tended materially in the end to their becoming better workmen generally, and more practically acquainted with the different husbandry operations on a farm. As no rule could, however, be laid down applicable in all cases, the following resolution was subsequently adopted:—"That where a surplus of labourers exist, and cottages are conveniently situated, the advantage appears in favour of employing week-men for the purpose of working horses on a farm, but under other circumstances yearly servants are to be preferred; although a mixture of both appears in some measure desirable, as tending to the better instruction of young servants, and to their ultimately becoming more generally useful labourers."

Miscellaneous.

On Fattening Sheep in Winter.—The subject proposed for February was, On the best manner of fattening Beasts and Sheep in the Winter Season. *Resolution.*—It is the opinion of the Members present, that the best method of fattening bullocks in the winter season is by giving them that description of food, which will deteriorate most by keeping; consequently common Turnips should be given first, then Swedes, and Red-root last. In all cases, the root to be cut into troughs, care being taken that they have the food regularly, and not too much by them at a time. With any cake food it is desirable to give good hay, with oil cake and Pea or Bean meal mixed together with a sufficient quantity of cut hay, in order that the corn may be consumed, without waste. The proportion of corn and cake given must depend on the size of the bullocks, the quantity of food in hand, and the time most desirable to get them to market. Bullocks tied up in a shed are considered to consume less food and to fat quicker than if allowed to range over a yard. Boiled linseed is also strongly recommended. In fattening sheep on roots, it is advisable to cut the same into troughs, and consume the food where it grows on mixed soil and light lands; by this method they may be confined in a fold, and made to go over the land in a regular manner and deposit the dung equally. Hay of good quality should be given sheep at all times during the winter season; and where quick fattening is required it is the opinion of this Meeting, that a pint of Linseed, each per day should be given mixed with cut chaff to the members present not having been in the habit of giving sheep oil-cake or linseed, do not feel confident to decide if either would be more advantageous than cost. *Keith Bennett, of the Liverpool Agricultural Society's Journal.*

Adulteration of Guano.—Four vessels recently sailed from Liverpool for guano stations ballasted with gypsum or plaster of Paris. This substance is intended for admixture with guano, and will enable the parties in charge to bring home a nice looking, light-coloured article, realising a large gain on the transaction. The guano is delivered upon the quays as it comes from the ships at Liverpool, and from the adulteration of guano alone a large gain is made. The rate of admixture, we are informed, is about 10 cwt. of gypsum to about 5 cwt. of Peruvian guano, from which an excellent-looking article, called African guano, is manufactured.—*Liverpool Paper.*

Guano.—We understand, by warrant from the Right Hon. the Lords Commissioners of Her Majesty's Treasury, dated the 17th ult., that guano imported from Ichaboe, or other places on the west coast of Africa, in British ships, and sold for the first time, is directed to be passed free of the auction duty of one-half per cent., hitherto charged on the sale of that article.—*Liverpool Courier.*

Notices to Correspondents.

Analysis of Guano.—*Dr. Nevington.*—See Paper by Dr. Ure in the last Number of the English Agricultural Society's Journal.

Bone Dust.—*Ullswater.*—It is not necessary that it should be literally dust, but it should be finer than half inch material: that which you describe, if spread on your Grass land, will act slowly, but for a long time.

Carcasses.—*Essex.*—See answer to a similar question in last *Gazette*. The flesh should be chopped up, and mixed and covered with vegetable earth, and the bones should be sold at the mill where you buy your bone dust.

Clay-burning.—*To Readers.*—Can any one describe the process of burning clay for ballast, as conducted on the Great Western Railway?

Depth of Sowing.—*W. C.*—We do not know Smith's hand-dibble. Wheat, Oats, and Barley, should be sown 1½ to 3 inches deep. With reference to the Grasses, see an Article by Mr. Stirling, published in this Paper not long ago. Mangold Wurzel seed should be dibbled not more than half an inch deep in rows 2 feet or more apart, and at intervals of 12 inches in the rows.

Fifth Paper.—*A Caledonian.*—Thank you. The letter by Mr. Grant has already appeared in our columns.

Gas Water, &c.—*W. B. G.*—It has been applied with useful result at the rate of 400 gallons per acre; but it must be remembered that it varies much in quality. Gas lime may be applied at the rate of 2 or 3 cart-loads per acre. It should be made into a compost with any vegetable refuse, and must be turned frequently before being spread. When thus exposed to the air it gradually becomes converted into gypsum. You cannot do better with surplus liquid manure than saturate mould with it, and then carry it to the field.

Liquid Manure.—*A Mid-Lothian Farmer* recommends to the attention of agricultural chemists the preparation of a soluble compound manure which, by the addition of water, might be converted into a liquid top-dressing for Grass lands. The sulphate of iron (green vitriol), is, perhaps, the cheapest fixer of ammonia we have.

Mr. Warnes' System of Feeding.—*A. O.*—It is adapted for dairy cows.

Salt.—*Subscriber.*—If you are inland, apply it to Grass land in wet weather in April, and to young Oats about the same time, at the rate of 1 cwt. per acre.

Saw-dust.—*W. P. P.*—There are three ways of using it:—you may soak it with liquid manure, and if you turn it frequently, it will probably, partially rot, and may then be applied to the land: or you may burn it and use the ashes; or you may apply it direct to the land, and perhaps this, on clay land, may be a useful manure. Of the last, however, we cannot speak from experience.

Sea Buckthorn.—*N. S. H.*—Thanks. Your communication has been anticipated.

Spent Bark, &c.—*Subscriber.*—We have applied it with benefit, first soaked with liquid manure, at the rate of about 10 cubic yards per acre. The compost of bark, soot, &c., which you propose, will in all probability be beneficial. Gypsum as it is sold, is just the mineral as it occurs in nature, reduced to a powder.

Swift's Works.—*J. F. S.*—It will have found in last Paper that he was anticipated.

Warnes' Pudding.—*A. Z.*—You must manufacture it at home. See Paper on "Flax-seed as Food," in the last Number of the *Gazette*.

Wheat.—*A. B.*—The young plant is folded over generally in April. On loose soils it is said to be beneficial. The quantity of land for a given number of sheep of course varies with the luxurriance of the Wheat plant. We shall, probably, have a word or two to say on this subject before spring.

Yearling Sheep.—*Constant Reader.*—They will fat readily enough on Linseed and hay. They will need water.

Miscellaneous.—*J. D.*—There are practical difficulties in the way, but we will consider the subject.

Markets.

POTATOES.—Southwark-Waterside, Nov. 11.

The prevailing east winds have prevented arrivals from the southern districts, but there have been several arrivals from the Channel Islands and Devonshire; yet the demand for the small stock of Kegs was not so good as was anticipated, and although 60s. was asked for the best kinds, this price may be considered nominal.

Joshua Mann, Hay Salesman.

Mark-Lane, Monday, Nov. 11.

There was a large supply of Wheat from Essex, Kent, and Suffolk, than we have received for several weeks, and the condition of the samples was much lowered by the damp weather, which made it rather difficult to effect a decline of 1s. per quarter on the best, as well as on other qualities. Foreign was in fair demand, but the Malt trade was dull. It was held checked the sale. Fine Malting Barley sold on about the same terms, but secondary and inferior qualities were 1s. lower. Oats, both White and Grey, are in better request, at 2d. to 3d. per quarter.

There is more doing in Beans at 1s. to 2s. advance.

Friday, Nov. 15.

The supplies of Corn and Flour during the week have been small, and the business transacted both on Wednesday and today was to a limited extent only. In Wheat, both English and Foreign, we observe no alteration. The very finest qualities of Barley maintain our quotations, but all other descriptions are a slow hearing sale. Beans, Peas, and Oats nothing fully as dear, the Market being badly supplied with all articles.

Duties on Foreign Grain [illegible]

SEEDS, Nov. 11.

Canary	per qr.	Linseed, Calcutta, Foreign, p. ton	77s to 80s	
Carraway	per cwt.	Mustard, White, p. bush.	10s	14s
Clover, Red, English		Superfine	12	16
— Foreign		Brown	12	16
— White, English		Hempseed, English, per last	32l	36l
— Foreign		Rape Cake, per ton	—	—
Coriander	per bush.	Linseed	—	—
Hempseed	per last	Tares, New, winter, p. bush.	5	6
Linseed	per qr.	Foreign	—	—
— Baltic	per last	Trefoil	—	—
— Cakes, Eng. per 1000		Turnip (very variable in quality).		

COVENT GARDEN, Nov. 16.—The supply of fruits and vegetables throughout the week has been good; but in consequence of the late heavy rains, trade has become somewhat dull. The prices of Pines and Grapes remain unaltered. A few Spanish Melons are offered, and occasionally one or two of English growth are to be seen. Dessert Pears are good and plentiful, the best being Marie Louise, Chaumontel, Glout Morceau, Passe Colmar, and Beurré Diel. Apples for tarts, of good quality, are also plentiful, and have not varied in price since our last report. Oranges are beginning to make their appearance, and the supply of other foreign fruit is good. Of Plums some of the late Imperatrice may still be met with, and Damsons, although very scarce, are still offered. A few Barberries are left, which are selling at 4d. per half-sieve. Walnuts bring from 12s. to 16s. per bushel; other Nuts are tolerably plentiful. Vegetables are for the most part sufficient for the demand. Asparagus, however, is becoming somewhat scarce, as it was last week. Cauliflowers are well supplied, and Cabbages, Savoys, and Brussels Sprouts are abundant. Celery of excellent quality is offered at about 8d. per bunch. A considerable quantity of foreign Horse Radish is in the market, and we also observed some fine American Shallots. Mushrooms have not altered in price since last week. Salads and other Sundries in sufficient for the demand. Among Cut Flowers we noticed Cypripedium insigne, and C. venustum, Azalea indica alba, Cyclamen persicum, Begonia rosaflora, Amaryllis, Chrysanthemums, Roses, Stocks, and Mignonette. Violets.

Pine Apple, per lb.	2s to 7s 6d	Filberts, per 100 lbs.	40s to 60s
Grapes, per lb.	1s to 4s	Chestnuts, per bush.	1s to 2s
— Spanish, per lb.	1s to 2s	— Roasting, per bush.	2s to 3s
— Portugal, per lb.	1s to 1s 6d	Walnuts, per bushel	12s to 16s
Melons, each	1s to 2s	Cobnuts, per bushel	12s to 16s
Plums, per half sieve	6d to 1s	Medlars, per dozen	1s to 2s
— Imperatrice, per pottle	6d to 1s	Services, per dozen	1s to 2s
Damsons, per half sieve	6d to 1s	Bullaces, per half sieve	6d to 1s
Apples, Dessert, per bushel	Americans 24s to 30s	Sloes, per half sieve	6d to 1s
— Kitchen, per do.	2s to 4s	Nuts, per bushel	10s to 14s
Pears, Dessert, per dozen	2s to 3s	Barcelona, per do.	12s to 16s
— Kitchen, per bushel	2s to 3s	Brazil, per do.	16s to 20s
Quinces, per half sieve	1s to 2s	Filberts, per do.	12s to 16s
Medlars, per bushel	2s to 3s	Cobnuts, per do.	12s to 16s

Cabbages, per dozen	1s to 2s	Onions, per bushel	2s to 3s
Cauliflowers, per dozen	2s to 4s	— Salads, per bundle	2d to 4d
Broccoli, per bundle	2d to 4d	Parsley, per bushel	2s to 3s
Brussels Sprouts, per lb.	2d to 3d	— Roots, per bunch	2d to 3d
Sorrel, per half sieve	6d to 1s	Tarragon, per bundle	2d to 3d
Artichokes, per dozen	2s to 3s	Capsicums, per 100	1s to 2s
— Jerusalem, per bushel	2s to 3s	Cucumbers, each	2d to 6d
Potatoes, per bushel	2s to 3s	Radishes, per dozen bunches	2d to 3d
— cwt.	5s to 6s	Celery, per bundle	1s to 2s
— Kidneys, per bushel	3s to 4s	Herbs, per bunch	2d to 3d
Parsnips, per dozen	1s to 2s	Chervil, per pottle	6d to 1s
Red Beets, per dozen	1s to 2s	Chamomile, per pottle	6d to 1s
Carrots, per dozen bunches	2s to 3s	Fennel, per pottle	6d to 1s
Scorzonera, per bundle	1s to 2s	Watercress, per bundle	2d to 3d
Horse Radish, per bundle	4d to 6d	Mint, per bundle	2d to 3d
Celery, per bundle	1s to 2s	Tarragon, per pottle	6d to 1s
Lettuces, per score	1s to 2s	Thyme, per pottle	6d to 1s
Endive, per score	1s to 2s	Lavender, per pottle	6d to 1s
Garlic, per lb.	6d to 1s	Marjoram, per pottle	6d to 1s
Shallots, per lb.	6d to 1s	Sage, per pottle	6d to 1s
Leeks, per bundle	2d to 3d	Rosemary, per pottle	6d to 1s
Mushrooms, per pottle	1s to 2s	Basil, per pottle	6d to 1s
Cresses, per punnet	2d to 3d	Hyssop, per pottle	6d to 1s
Chilies, per 100	1s to 2s		

SMITHFIELD, Monday, Nov. 11.—For some of the best breeds, more money, &c. [illegible]

Friday, Nov. 15.

We have received but few Beasts for this week, and in with difficulty obtained for the best kinds, fully equal to the previous Monday's Horses. Inferior qualities are heavy of sale from 2s 6d to 3s 6d per 8lbs. The supply of Sheep is rather short, and the trade somewhat better than last Friday; but we cannot discover any improvement on Monday's quotation. Downs, &c. 4s 6d to 4s 8d. Best Long-woolds 4s 4d to 4s 6d. Veal trade heavy trade at from 4s 2d to 4s 4d. Veal trade is comparatively heavy, and is considered an extravagation for the best qualities. Pork trade is very heavy, and it must be very good quality to make 4s 4d.

Beasts, 7824. Sheep, 31,140. Calves, 180. Pigs, 290.

nervures scarcely visible; halters long and capitate; length four and a half lines; breadth nine. Female larger and darker; head very small and oval, scarcely the breadth of the thorax; eyes small, lateral and remote; ocelli similar to the male; thorax large and full; colour distinct; abdomen large, broader than the thorax, emarginated at the base, the apex trigonate, with two little nipples; wings very ample, fuscous; the costal nervure and stigma darker, as in the male; halters black; antennæ the longest; anterior thighs enlarged; posterior scarcely; the legs are similar to those of the male; length six lines, breadth 13 (fig. 3).

The female lays her eggs in the earth, and in the dung of horses and cows in May; they do not hatch until August; it may therefore be presumed that they are feeding at least seven months, viz., until the following spring. During May the flowers in the fields and meadows around London swarm with the Bibio hortulanus, and about the same period the fruit-trees in our gardens, and even the streets of the metropolis, are frequently visited by multitudes of the large and sombre-coloured Bibio Marci, whose flight is heavy and very peculiar in the males, the body hanging down, the long hind legs being stretched out like a heron. The larvæ seem to require a great deal of moisture, for they soon die if taken from the soil they inhabit.

Bouché says the best remedy against these larvæ is hand-picking, which is not attended with any difficulty, for the localities they inhabit are readily discovered in the spring, by the fine earth which is turned up where they live in society. He cleared his Ranunculus-beds of them eventually, by changing the earth in the autumn, and bringing in fresh which was free from the larvæ, and thus annual renewal of the earth seems to be a sensible and easy remedy.—*Auricula.*

Rural Correspondence.

Pruning Timber-trees.—Without any previous conversation on the subject, I went to ask the opinion of an old timber merchant of Sussex, the question was put to him of how he would prune an oak? His answer was, "Not at all—only upon an ash puts forth a useless shoot till it begin to ripen its wood, when it." In further observations, he went on to say, that you might keep a clean stem whilst the tree was young, so that you did not interfere with his tops, but not afterwards. If you pruned, you hindered his growth, and made his timber *dotted* (unsound, or filled with rotten knots). This person resides in one of the well-wooded parts of Sussex, and has had ample means of observing the growth of the commodity he deals in. It may be observed of the coppice Oak of Sussex, that in the copsing state it is very much overgrown by under-wood (Hazel, Ash and large Oak), and so pushed up with long and slender stems, which speedily acquire strength, when freed of that incumbrance by periodical cuttings, and, if allowed fair play, soon overtops, and eventually overshadows and destroys the underwood. In this way the best carpenter's timber is produced; that is, long and straight stems. In the periodical cuttings above spoken of, a straggling low branch on a sapling is sometimes struck off by the forest-maker, but no other pruning is practised. The same is done with the tillars or tellows (young Oak of hedges and hedge-rows; but here larger and shorter stems are produced by the free and unincumbered growth of the branches, and the result is the best knly timber, of which much is cut into plank before it is sent off. Very little Fir is grown in Sussex for economical purposes, except in a narrow strip of country in the central parts of the county. Here the trees seem to do best when left to themselves, only having their stems cleared of branches as they die off in the shadow of the overgrowing tops, so that the wounds may close in before the knots become rotten. It may be mentioned incidentally that, not of late, but it is almost within the memory of man, the lop and top of a broke of timber in the west of Sussex has been known to sell for more than the timber itself.—*P. P.* [We particularly commend this statement to the consideration of timber-pruners. Like all the statements of our excellent correspondent, it is full of good sense.]

Pruning Timber-trees.—In reply to "C. C. L. D." of the Wicklow mountains, who, if I understand rightly, objects and demurs to Mr. Billington's opinion, I will maintain that that is not the case. Mr. B. has never by anything of the which I have read, induced me to change or modify any opinion I previously held. It may be quite true that I hold some opinions in common with Mr. B., but these were not certainly formed by his writings. Again, "C. C. L. D." misapprehends me when he says, "I desire no better authority than Mr. Billington." It is true I used that expression, but it referred merely to Mr. B. as a reporter of the real state and management of the Nerquis plantations, and nothing more. I considered him a competent, honest, and experienced reporter, and such was the ground of my confidence in the accuracy of his testimony. As the Nerquis Plantations appear to have been visited by gentlemen from various parts of the kingdom, I would invite such as choose, to make their opinions known through the medium of the *Chronicle*.—*Quercus.*

Cyclamens.—If these are now in bloom, with liquid guano they will furnish splendid heads of flowers. I have some under the above regimen which are flourishing amazingly, many of the flowers measuring three inches across and nine inches in circumference, and these to be had not in single blooms.—*G. F. W.*

Hyacinths.—In cultivating these, prepare the four following soils in equal proportions, viz., loam, peat, rotten manure, and leaf mould; let them be well incorporated together. Procure deep pots, and place some broken potsherds over the hole, on which put some rough peat broken in pieces; fill the pots with the compost to within three inches of the rim, and put the bulbs on a little sand; then completely cover it over with the same, which will keep the bulb clean and in a uniform state as regards moisture, filling up the pot with the compost. Water it with a fine-rosed watering-pot. Let them stand till they get pretty dry, then plunge the pots over in cinder-ashes or sawdust anywhere under cover for a month; at the expiration of that time they will begin to push through; they may then be exposed to the light and air, and as they advance in growth water them with guano, which will cause strong flower-stems to be thrown up, and add greatly to their brilliancy of colour. After flowering they may be planted out in the open ground, in an airy situation, and the leaves allowed to die off gradually; then taken up and kept in a cool dry place. Treated in this way, they will flower every year.—*Flora.*

Destruction of Red-Spider, Thrip, &c.—"Delta," at p. 749, mentions the circumstance of a Paper having been read before the Horticultural Society of London, Aug. 2, 1837, respecting Laurel-leaves being used, when bruised, for destroying these pests. As a practical man I can speak from experience on this subject. Being in the habit of growing Melons and Cucumbers rather extensively for some years, of course I have been troubled with these insects as well as my brother gardeners, and this year rather more than usual. The method that I have adopted for many years for killing the red-spider, thrip, and green-fly, is as follows:—When the plants appear attacked with these insects, I get a quantity of Laurel bruised, and put it into the frame or frames, as it may be, about 3 o'clock P.M. It should be dispersed all over the frame, but by no means allowed to touch the leaves of the plants—for, if you do, it is sure to affect them very materially; then shut down the lights as closely as you possibly can; and should the sun be very fervent at the time, I always throw a single mat over the frame, in order to prevent the leaves of the plants from being burnt. The heat to which I allow the frame to rise is from 90° to 100°; never allow it to rise above that point, or you will be sure to lose plants, crop, and all. The length of time that I allow this heat to remain in the frame is two hours only; this time may perhaps appear short, but such is the fact. About 6 o'clock the mat is taken off, and a little more air is admitted to the plants. On the next morning, the Laurel is all taken out, and the plants are well syringed with warm water, and of course shaded during the day. I am certain that, by the evening of the second day, there is not the slightest appearance of thrip or spider. If "Delta" will try this plan, he may be sure of success.—*Devoniensis.*

Glout Morceau Pear.—"R. T." in his description of this Pear, (p. 716), suggests that the meaning of the word "Glout" may be explained by the synonym "Goulu," which he says "was recently observed in the Catalogue of M. Henrard, of Liége." "Pois Goulus," according to Chambaud, "signifies Sugar-peas, Honey-peas. The Pear in question may be accordingly termed a sugared or honied morsel." Now the only signification of Pois Goulus in the Dictionary of the Academy is, "Peas of which the shell or husk is eaten, because it is tender, and has not that small hard interior membrane which is found in other husks." If, therefore, Glout is to be considered the same as Goulu, may not the Pear in question have been so named from the extreme fineness of the skin, which may be eaten more easily than the skin of most Pears? The Dictionary of the Academy gives no other signification to the word "Goulu" than "Gluttonous," and it is, I apprehend, applied in that sense to the above-named Peas, as the eating shells and all has doubtless rather a greedy appearance.—*Guickenot.*

Botanical Lectures, &c.—In Hogarth's Works, published in 1808, by Longman and Co., and edited by Nichols and Steevens, I observe the following notice in a note at p. 348, vol. I., under the date 1762:—"That Dr. Mascll, Curate of Kew, Twickenham, &c. preached, for several years, the Botanical Lectures at Shoreditch Church." Did you ever hear of this lecture, or can you inform me whether it is still delivered? If a sum of money has been left for such a purpose, and it has been diverted to another, perhaps it might be possible to recover it, and use it according to the donor's intention. Such a lecture would now be very gratifying to many, though want of encouragement no doubt was the cause of its dying away. Can you likewise inform me if the Boyle Lectures are still delivered, and in what place? A competent hand these likewise might be made very interesting and acceptable.—*T. G. H.*

Cabul Melons.—I quite agree with Mr. Fleming with regard to the Hoosainee and Cabul Melons. I observed at the time at which Mr. Cuthill's advertisement appeared in the *Chronicle*, that he took the Hoosainee to be the Cabul, or rather the Trentham Hoosainee to be that variety. With respect to the Trentham Hoosainee, of which Mr. Fleming is proud, I have little to say; but this I well know, if as he says it is a free bearer and exquisite in flavour, it is the first hybrid that ever was of any use. I wish to be properly understood: if it is a good hybrid Melon it is one of the first that ever was really good. We too often find Persian Melons hybrids in this country, and that to the utter ruin of sorts. The kinds that Mr. Fleming chose for his parent plants are both good when well grown; still, strange as it may appear, they seldom or ever produce good hybrids, however careful one may be in performing the operation of hybridising: this I have proved. I have known many gardeners to have produced what they call their hybrids; and what are they? Any thing but good. I am fully convinced that the flavour of a Melon depends much on the cultivation, or the cultivator, if he is in possession of good and true sorts. I have known seeds to be given to two gardeners out of the same packet, of the true Ispahan Melon, sent to me direct from the city of Ispahan in Persia, from which I believe it takes its name: the produce of one was very similar to that of the Vegetable Marrow; and the produce of the other was fine Melons from 6 to 8 lbs. in weight, and of a most excellent flavour. This cannot always be said of hybrids, but quite the reverse; they are more like the former, Vegetable Marrow, however good the treatment may have been. I have grown the Hoosainee, (but not Mr. Fleming's Hoosainee) the original one: it is a good bearer, and as hardy as most of the Persian sorts, excepting the Germek. I have grown a hybrid between the Ispahan and the Green Hoosainee, which turned out to be very little better than one of the old useless kinds. I may mention that I have also grown the Cabul Melon in question for the last five years, seeds of which were sent to me by a friend in India: it is a very delicious Melon, thickly netted, and possessing a sweet melting flesh. Last season I grew 18 good fruit, the produce of a first crop, in a 3-light box, and 19 of a second crop; thus making in all 37 good Melons from 6 plants. This Melon has one great advantage over many others, viz., the good property of keeping for a length of time after being cut: I have known it to keep good for 5 or 6 weeks. On the 19th November last year I sent the last fruit to table.—*W. M. Donald, King's Road, Chelsea.*

Almonds.—It is not generally known that the Almond (*Amygdalus communis*) ripens in this country, and in favourable summers, such as our last, produces a large crop of well-ripened fruit, which makes a very nice addition to the dessert during winter. They should be gathered in November, stript of their outer shells, and laid out to dry for about three weeks, or placed on shelves in the fruit-room; afterwards let them be kept in very dry sand, and used as they are wanted. They must not be left in a damp place, as they speedily lose their aromatic flavour, and decay in our moist climate.—*J. R.*

Fuchsias.—Perhaps it may not be generally known that at this season, when Fuchsias have done flowering, if the strong shoots are divested of their lateral branches and tops, and packed in powdered charcoal, or perfectly dry earth in boxes, and placed out of the reach of frost in a cool place, they will retain their vitality until next April, when they may be cut into lengths of about a foot long, and planted with a dibble; insert them into the ground so as to leave about three inches of the cutting above the surface in any place where they are wanted to flower next summer. If kept tolerably moist they will be found to make good flowering plants with little trouble, and to any extent that may be required, the sorts that I have tried are Globosa, Globosa major, gracilis, virgata, and conica; they were packed in powdered charcoal on the 27th of October, and planted on the 6th of April. They flowered very well.—*A. C.*

The Mealy-Bug.—I wish you would call attention to Herreman's lotion for destroying the Mealy-bug, which is such a pest in our stoves. His printed paper does not do him justice, for it conveys an idea that the small-sized bottle will not be sufficient to effect near as much as it can really do. The only objection I had to make was the high price of the lotion, which would prevent its being used as freely as might be wished. He has since sent me a modified preparation, concerning which my gardener writes me word that he finds it equally effectual and less likely to injure the foliage; and that, I believe, Mr. Hereman will be able to sell at a lower price. I found the first lotion very effectual and harmless to the leaves in general, but in some instances hurting them very much, if not washed off speedily; but it proved quite harmless if washed off soon after the application.—*W. Herbert, Manchester.* [We should like to hear the experience of our correspondent's who have used this substance. This statement in its favour, by the Dean of Manchester, is very important; for certainly, if there is one thing more troublesome than another in glass-houses, it is this Mealy-bug. We must, however, beg those who may favour us with communications, to authenticate them by their signatures.]

Medlars.—As this is the proper time to gather the above, I would advise their being kept in the following manner, which will effectually prevent them from acquiring that dry rotten state, or tart disagreeable flavour to which they are so liable:—Select a day day for the purpose, and see that none are bruised; have them placed singly on open shelves in a cool place, and look them over once a week, and the moment one is found decaying (not ripening), remove it, as one will taint the whole. They are much affected by a minute Fungus, which spreads in an incredibly short time, and destroys an immense number. By attending to these directions, this fruit will be eaten in perfection, which is seldom the case in this country.—*J. R.*

Brewing.—If the brewing of beer comes within your limits, I should be glad to be informed whether or not boiling the wort is necessary, either for making the liquor more palatable, more wholesome, or less liable to become stale or flat, or rapid in its progress. I am told that boiling it not necessary for any one of these, and that some persons make the very finest quality of ale without ever boiling it.—*Ignoramus.* [It is the general practice to boil the wort with the hops, and opinion says that the more it is boiled the better the beer will keep. But some correspondents may, perhaps, be able to furnish a better answer to this inquiry. How is Preston Pans ale made? The very best that can be bought.]

To preserve Yellowhall Pears.—Take half a peck of Pears, pare them, and, leaving the eyes and stalks on, put them into a pan with as much boiling water as will cover them; add a pint of Damson syrup; let them boil until they are tender, then put them into jars. Take the liquor in which they were boiled, and add to it one-third of sugar, and boil and pour it over them. Repeat this on the second day, and on the third do the same, putting in the other two-thirds of sugar. Let it boil until it is perfectly clear, and pour it hot upon the fruit; when cold, put brandied paper over them, and tie closely. Two pounds and a half of sugar is the quantity for half a peck of fruit. The above is a copy of a receipt I had given to me some years ago. I found the Pears liable to ferment in consequence of (as I supposed) the fruit not having been boiled in the syrup. I consequently stewed them in a third part of the sugar, reboiled the syrup, adding a little more sugar, and finished them as above directed on the third day. In this way they keep well. A little bruised ginger boiled or stewed with them is an improvement, and gives them the flavour of Indian preserves.—*A. W.*

Peas.—In consequence of an advertisement or recommendation in the *Chronicle*, I purchased a quart of Cormack's British Queen Peas. I imagined before that I had very good kinds, but find this very superior in every respect to any Pea I have yet grown. It is a great bearer, excellent in flavour, of a large size, and the straw is not of an inconvenient height. It is decidedly the best Pea I know, and I think that others who try it will agree with me.—*W. D. F.*

Bees.—The following is an account of a common straw-hive, taken by me on the 5th October, 1844. The weight of the hive with the comb, immediately after the bees were destroyed, was 58lbs. avoirdupois. I reckon the hive and combs to weigh 20 lbs., thus leaving the great weight of 50 lbs. for honey. This, I imagine, is an extraordinary quantity to be gathered by a swarm of the present year. It was swarmed in the latter end of June. —*A Subscriber, Devon.*

Morphology.—The numerous supporters of the somewhat astonishing doctrine of Morphology, which from time to time appear in the *Gardeners' Chronicle*, have caused the matter to be noticed by novices like myself; and whether the originators of this—to me—wild doctrine are correct or not, is of little consequence to persons of my humble pretensions. But if Morphology is to be received by your readers on the grounds set forth by T. Moore, at pages 685 and 686 of the *Chronicle*, I for one cannot subscribe to it. Our author says, "It may be remarked, too, that several of the Achimenes, and *A. pedunculata*, especially, should be regarded as plants of a very suspicious character by the opponents of this doctrine; for in several cases during the past season, it has been observed that this *A. pedunculata* has produced scarcely any flowers, but in their usual position abundance of little scaly bulbs have been protruded; here, what should have been flowers have been developed as bulbs." In a specimen of the old Cyrilla pulchella now before me, which is a near relative to Achimenes, there are whorls of flowers, and between the bases of the underside of the flower-stalk and the leaves, there are whorls of scaly bulbs, which is evidence sufficient that the said bulbs do not protrude themselves where the flowers should be situated, but the proper place for them is so near that the flowers, scaly bulbs, and leaves, mutually touch each other; therefore the supporters of the doctrine of Morphology should be careful not to do so by hasty observation, as in this case; for in those very plants which our author states "should be regarded as plants of a suspicious character by the opponents of this doctrine," are seen distinct situations for both leaf, scaly bulb, and flower.—*Gardeners' Weekly.* [You are right. The scaly bulbs formed on the branches of inflorescence of the Achimenes are reproductive buds, assuming the form of bulbs; and though it may be argued that since leaf-buds and flower-buds are formed on the same plan, therefore the scaly bodies of an Achimenes being altered leaf-buds are equivalent to flowers, yet such a line of argument is not a good one, for the purpose of convincing persons unable to comprehend the principles of Morphology; which principles are true and irrefragable.]

Dogs' Scent for Game.—There is a notion that dogs lose their scent, or smell for game birds, during the time of incubation; that, however, I consider to be wrong. I think it is more likely that the birds lose, or rather do not emit, scent or smell during the time in question, and hence the notion. I mentioned this to a gentleman well acquainted with dogs and game, and he told me the following in favour of what I have advanced. He was once aware of a partridge's nest that was "hard set upon" near where a party of Gipsies had fixed their abode; although they had three dogs with them, yet the wary bird led off her brood three days afterwards. There must be some truth in what I have stated, otherwise the smell from the bird on the nest would have led the prowling dogs upon her. If my views on this subject are correct, it shows a wise provision of Nature to protect birds from harm during incubation; for if it was not so, they must often fall a prey to canine animals. It may be asked, How does it happen that birds do not emit smell while sitting on eggs? That may be owing to the habit or condition of birds being changed; or during the time of incubation they lose in a great measure, although not of self-preservation.—*T. W. Wilson.*

Vines on Open Walls.—After reading Mr. Harris's book upon the Cultivation of Vines on Open Walls, I adopted the plan which he recommends, and have now a considerable quantity of Grapes which are at last getting as well coloured as if grown under glass, to the surprise of every one who sees them or tastes them. I am living in latitude 52° 54'. The wall is a little east of south; it faces the sun at 11 A.M. The Grapes have been quite ripe about a fortnight; some of the bunches sooner.—*C. A. A., Lloyd.*

Small Birds.—Being an imitator and admirer of Mr. Waterton, my garden has for the last six years been a rendezvous for all the birds in my neighbourhood; and although often remonstrated with by my gardener, I stood firm for some time. I was first shaken by seeing four bullfinches strip, in early spring, nearly every bud from a Greengage tree: I could not be mistaken, as I tried to persuade myself that they were only hunting for eggs of insects, aphis, &c.; but the stripped trees and the strewn buds would, I think, have satisfied Mr. Waterton himself. My soil being cold, my Apples and Pears have remained on (the late soils) till now; having many small trees of new sorts with three or four fruits on, I was sorry to find that nearly every one of them had been attacked by birds. I believe the blackbirds have some of the blame to bear; but the principal performer is the little blue tomtit, already outlawed by reason of his attacks on the Pees. I did not find Mr. Knight's traps very successful. Can any one advise me as to the most successful mode of extirpating this garden enemy?—*Dodman.*

The Kingfisher's Nest.—Of the various materials and modes adopted by birds in the construction of their nests, those of the kingfisher are perhaps the least understood. The bird is found everywhere throughout Europe, and its brilliant plumage strongly contrasts with the little show made by most of the feathered tribe in this country. What early writers tell us of the kingfisher is so mixed up with the fabulous and ridiculous, that little reliance can be placed upon their accounts. Pliny says—"Their nests are wonderful—it is not discovered of what they are formed; some think of prickly back-bones, since they live upon fish." Bewick mentions that he had a kingfisher's nest with six eggs, "which resembled that of a chaffinch; it was made entirely of fish-bones, cemented together with a brown glutinous substance." He also relates Dr. Heysham's account of a boy finding a kingfisher's eggs in a hole "half a yard in length; at the end of it the eggs, which were six in number, were placed upon the bare mould, there being not the slightest appearance of a nest." My own knowledge of the kingfisher's nest is somewhat different from the above. I have found them in holes; but the eggs were not on the bare earth, but placed on a bed of very fine particles of fish-bones, not cemented together, but loose, and just hollowed out a little in order to receive the eggs. Part of one of those nests is now before me, which is very friable. It contained six eggs—the usual number of this interesting bird. The eggs are of a very delicate white, and are much like polished marble. It may be interesting to know how the bird procures these small fragments of fish-bones, to form its nest. They are evidently the pellets which these birds disgorge after eating fish, in the same way that owls and other birds bring up the fur and feathers of their prey in small balls; those of the Kingfisher have often been found in places which they frequent, of an oval shape about the size of a small Acorn. It is probable, however, that the small fragments are only those disgorged during the time of incubation. This corresponds with the boy's story already noticed, as well as with the statement of a writer in the "Museum of Animated Nature," who observes that the "kingfisher rejects the indigestible parts of its food, a circle of these *rejectaria* surrounds the eggs, and after the young are hatched is greatly increased; and hence has arisen the supposition that of pellets of fish-bones the nest is composed. This might induce the idea that after all that had been said of the kingfisher's "wonderful nest," it consisted merely of a few ejected pellets surrounding the eggs, which were placed on the bare ground. This however, as already mentioned, is not the case: for the cavity or nest is as nicely lined with fine particles of bones, as the nests of other birds are with softer materials. The ordure of the brood may cause the bony fragments to adhere together; and so may have given rise to the old notion that the nest of the kingfisher was composed of bones cemented together. Although this bird pastes for its nest some place seldom disturbed, except by the patient angler, I have found the kingfisher's nest in a gravel pit a quarter of a mile from a brook, in the act of digging or boring a hole for its nest, which is usually three or four feet in length. Bewick seems to credit the less that frequently the hole which leads to the nest is under water, but those who are acquainted with the habits of the kingfisher know, that though it darts into the water after its prey, it never enters the water like other water-birds. Perhaps the best way to ascertain if birds line the nest with bones before incubation, is to examine a nest when the bird begins to lay.—*J. Wighton.*

Moving Fruit-trees.—Mr. Van Houtte, of Ghent, in his Catalogue, just published, observes that as regards Peaches, it is particularly to be recommended that they should not be moved till after the sap is completely out of the leaves and at rest; otherwise, much injury may arise. This does not appear to be consistent with the directions given in this country, to plant wall-fruit as soon in the autumn as the leaves begin to turn yellow. He also, like others, recommends the gathering Pears as soon as the stalk easily separates from the branch; and adds, that if the fruit is left on till the leaves change colour, the quality of the fruit is much impaired. What is the experience of your correspondents as to this?—*Dodman.*

Beurre Diel Pear.—In notices to Correspondents, p. 702, it is stated that a specimen of Beurre Diel Pear measured 14½ inches in girth, and weighed 18½ ounces. I beg to say that I have gathered eight Pears of the same variety, each measuring 13 inches in circumference, and weighing 16 ounces; they were from a young tree 6 feet in height, and which measured at the height of 1 foot from the ground, 11 inches in girth.—*D. Murray, Gr. to W. M. Reeves, Esq., Cork.* [Correct.]

Pear-trees Improved by using Dressing with Sand.—I find sand from the north coast of Cornwall to be the best dressing for Quince Stocks, on which I graft all the best kinds of Pears; the sand is composed of from 90 to 95 per cent. of lime, from the shells of fish. I have 150 sorts of Pears grafted on Quinces—most of them are twice grafted, in order to insure their growing strong—they are in full bearing. Some years ago I accidentally got a cargo of Dutch sand, which was disposed of in the Pear garden, and from that I found sand to improve the trees much. I followed up the idea, and got a cargo from Hugh, in Cornwall, which is nearly all shell, and from that time my Pears are very fine, and more juicy than formerly.—*Alex. Penlay.*

Strawberries.—I should object to "M. A. S.'s" tiles, (see p. 701) as well as the Editor's plan of paving, as they obstruct the escape of effluvia from the ground, which I consider necessary for the growth of the plant and perfection of the fruit. Detached pieces of stone, tile, or slate, placed under the fruit, are not subject to this objection. If "M. A. S." chooses to tile so compactly, let him spread over the tiles some guano, which will not only feed the leaves of the plants, but give a peculiar perfume, if not flavour, to the fruit.—*J. M. Goodiffe.*

Bokhara Clover.—"B. D. Grey's" (see p. 702) seems disappointed in this only partially blossoming; it is a biennial, and of course does not flower until the second year; it grows 3 or 4 feet high during the first year, and considerably higher the second. In favourable situations it is said to attain the height of 11 or 12 feet; it should be cut for fodder, when about 2½ feet in height; it is of very rapid growth, and may the second year be cut monthly; it is very branchy. I sowed some in July, and it grew the same year by Michaelmas, nearly to 2 feet in height. I then left the neighbourhood; but have heard that it grew up like trees in the next year. I should sow it in drills.—*J. M. Goodiffe, Greenard.*

Bee-flowers.—If "B. D. Grey" wishes to provide for his bees, I would recommend Borrach (Buck or Brank) Wheat; they are so very fond of the blossom that he will not only feed his own bees, but those of his neighbours for miles round. I had 2 acres of it once (not sown till the first week of July, to ascertain how late it might be sown with a chance of a crop), and every blossom was scarcely ever without its attendant bee, though I had none of my own. Successions of it might be sown for the bees from April till the end of July; mine blossomed within a month after it was sown; but it cannot stand frost; it is its only enemy, but an invincible one. For a seed-crop it should not therefore be ventured on later than the end of June. Some crops I hazarded later were destroyed by night frosts.—*J. M. Goodiffe.* [It is not fond of clay land.]

The Pinaile Grossbeak.—The description of this bird's nest, p. 670, is very entertaining, as accounts from Natural History must ever be to those who are not eye-witnesses of the facts stated. I have before me, as I write two wasps' nests, one of the size of a hen's egg, built on a comb in a hive which the bees deserted; the other is a pensile nest, as large nearly as a human head, being 18 inches in circumference either way. It was built at the extremity of a branch of a Larch, the builders ingeniously taking into the web the smaller twigs, as a support to the structure. Both nests are formed of numerous lamina of the same material—a very thin papyrus, as it may be most justly called, of a greyish colour, and rather glossy. The cells in the combs of both are open at top, others are carefully capped. In the former are seen young wasps perfectly formed, but motionless. Should these not resuscitate in spring, and be cut open as from the chimney-piece of our sitting-room, where their habitations are now a handsome ornament as well as a great curiosity, all will be safe.—*E. G.*

Flower-beds.—I have a geometric garden, which I purpose to fill next year with beds of hardy plants; but I do not wish to have it gay before such plants bloom in the open air, and shall be much obliged to any of your correspondents who will give me a hint on the subject. I am provided with Geraniums, Cockscombs, &c., to fill up when the beds are required for Pelargoniums, &c.—*E. M. W., Chertsey.*

Weather in the North.—Let a singular circumstance, that whilst we have been hearing of heavy falls of rain in the southern and midland counties of England, no rain at all has fallen here since the commencement of this month; dry easterly winds, resembling the weather of March, have prevailed, the temperature ranging from 38° the minimum generally 40° Fahrenheit, by night, to 48°, the maximum by day. The Dahlias continue still

in flower in the gardens, and other half-hardy plants remain blooming in the open ground.—*Gardener's Mag. Lancaster.*

The Grey Wagtail.—This bird has found its way here again this autumn. I saw the species in the village as early as Sept. 11; but we had not the pleasure of its visit until the 9th of this month, on the morning of which day I heard the well-remembered tapping at the window as much frequented last year. It did not, however, remain (as I am inclined to believe) for any considerable time in much better condition than when it arrived last autumn. I now see him in company with another of his kind; but only one appears at the window, and that much seldomer than before.—*S. Stratford.*

Boiling for drying Fruits for Dessert.—Pare the pears and leave the apples on; cover them with water, and either boil in a brass pan, or stew in earthenware, until they are tender; then lay them upon old dishes, and put them in a slow oven 24 h. or more, turning them gently, that all parts may dry equally; when done put them in paper bags, and hang them in a dry place, or keep them in tin canisters or boxes. Reduce the water in which the fruit is boiled, and by constantly using this for the succeeding operation, a syrup is obtained, which gives a gloss to the fruit, as if sugar had been used. I never use sugar for them.—*A.*

White Beet.—Is the White Beet or the Chard, the true Mangel Root of Switzerland and Germany, the leaves of which are so much used in the place of Spinach? What was distributed as "White Beet" by the Horticultural Society? All I can perceive, produce leaves so fine as that which is grown in Switzerland. This may possibly be owing to the leaves not growing so luxuriantly as that cultivated abroad. I observed some of these from 3 to 4 feet in length.—Liquid manure being very plentifully applied.—*Dodman.*

Lettuce-leaved Spinach.—I may observe, that the Spinach, the seed of which was distributed by the Horticultural Society, under the name of Lettuce-leaved, proved excellent, tender, and high flavoured, and stood last winter well, though the leaves appeared far more tender and succulent than the common winter sort. I found transplanting a portion of the plants, when too thick or too forward, a good plan, and produced a good late crop for the spring, just before the first sowing crop came into use.—*Dodman.*

Whitney's Composition.—A friend had several boxes made in the shape of a small garden light box, some 3 feet and some 2 feet 6 inches square, about 6 or 8 inches at the back, and 4 inches in the front; these I covered with thin paper, and varnished it over with Whitney's preparation. They have answered admirably for cuttings, and my gardener finds them an admirable and economical substitute for hand-glasses; any old packing-case cut into two diagonals, makes a pair of useful frames. The muslin I found too thin, as I could not apply sufficient of the mixture to exclude the rain.—*Dodman.*

Societies.

MICROSCOPICAL SOCIETY.

Nov. 1.—T. Bell, Esq., in the Chair. A Paper was read by Mr. Busk, on the Echinococcus, a form of Cystic Entozoa. After giving a slight sketch of the history of researches on the Entozoa, the author proceeded to describe the Echinococcus. This Entozoon is developed in a nutritious cyst, which is found in the liver, lungs, and other viscera of human beings, and other classes of the Mammalia. The cyst in which the Echinococcus is contained has its internal parietes covered with rounded granular masses. On examining these masses, they are found to consist of a number of globular bodies, seated on a common receptacle, of a branched form, and covered with a delicate membrane. The globular bodies are the Echinococci. Each is attached to a pedicel, and the whole are united to a common trunk. When separated from the trunk, they appear like polygastric animalcules. Each globular body contains several transparent cells, like the stomachs of Polygastria. The head, or jaws, consisting of a row of hooked tentacles, is retracted within the cavity of the body; but during decomposition, this apparatus becomes exserted, thus having led to the different characters given to this animal. The Paper was illustrated by drawings and diagrams. The President announced that arrangements had been made for facilitating the use, by the Members of the Society, of the splendid microscopes of the Society. The rooms were open every Wednesday from 10 to 4, and members would be allowed the use of the microscopes under the superintendence of Mr. Leonard. It was also announced that the second Part of the first Volume of the Transactions of the Society was ready for distribution to the Members who were not in arrear with their subscriptions.

SOCIETY OF ARTS.

Nov. 6.—T. Gowen Barwell, Esq., in the Chair. Silver Medals and Premiums were awarded to Messrs. Goodwin, Porter, Mr. Major, Mr. Bush, and Mr. Hunt. Eagles and Dr. Cronin were elected members.

Nov. 13.—R. Kewaigne, Esq., in the Chair. A Paper on British and Foreign Honeys by Mr. Milton,* was read by the Secretary. Various specimens of honey from Athens, Mingrelia, Portugal, Narbonne, and different parts of England and Scotland, were placed on the table; also the produce of bees kept in glass hives by gentlemen in the Temple and the Regent's Park; a single comb, in particular, in worthy of notice, as having been taken from a newly-invented hive, so constructed as to afford bees in the disposition of their work, which, however, in the present instance, is not perfect, for some of the cells instead of being regular are irregular hexagons. The author of the Paper, however, was not without doubts of ultimate success. A detailed account is given of the structure of the honey-bee, of the mechanism employed in the construction of the comb, of the flowers best suited to produce honey of the finest flavour, of the best seasons of the year for taking the honey, of its medicinal qualities for various diseases, of the quality of honey produced in different parts of England under different circumstances of management, of the encouragement given to cottagers to keep bees by a gentleman in the vicinity of the Westmoreland lakes, and, lastly, of the great profit to be derived from bee-keeping.

THE FOLLOWING IS A LIST OF THE SAMPLES OF HONEY EXHIBITED ON THIS OCCASION:—

English Honey.—1. Oxfordshire Honey, weight 22 lbs.; 2. Regent's-park Honey, weight 16 lbs., collected by the bees of S. Hodgson, Esq. (the glass was put on the 27th May, 1843, and taken off the July 31st); 3. Regent's-park Honey, weight 14 lbs., was filled by a swarm from the above, 4. In a Honey-Maida-hill, weighs 20 lbs., was collected by the bees of C. F. Monkhouse, Esq. (glass put on the 2d of June, 1843, taken off July 20th); 5. Honey from Hackney, bees belonging to A. Smart, Esq., weight 14 lbs., June and July, filled by the bees in 38 days; 6. Honey from Mill hill, Hendon, bees belonging to the Rev. B. Nicols, weight 21 lbs. (the straw hive from which this cap was taken now weighs 40 lbs; 7. Honey from Fulham, worked by the bees in a flower-pot; 8. Honey from a Baxter hive, worked by bees at Chertsey; a comb of Honey, worked in a frame by bees belonging to the Rev. J. E. Gray, of Wembly-park, near Harrow; the bar-and-frame hive was invented by W. A. Munn, Esq., and constructed to direct the bees in their building of comb, and do without a guide-comb; Honey from Northumberland is slightly flavoured with Heath; Honey from Saffron Walden, Essex, equal to any; English Heath Honey, from East Hampstead, near Bagshot; Comb Honey in the plate, from Scotland; Comb Honey in the plate, from Fulham.

Foreign Honey.—1. Minorca Honey, small jar, just as imported; 2. Minorca, opened for the purpose of tasting; 3. Narbonne Honey; 3*. Normandy Honey; 4. Italian Honey; 5. Portugal Honey, imported in jars, very similar to those from Athens; 6. Honey from Hymettus, in antique jars, one specimen; Cuba Honey is imported in large quantities, sells at a very low price, and serves to keep all the inferior qualities of Honey at a low remunerating price; Jamaica Honey set firm—Jamaica Honey not set, has been imported to England 10 months; Seville Honey, rather of the Jessamine flavour; Portugal Honey, flavour of the Wild Raspberry; Honey from Devonshire—it partakes of the flavour of the Portugal Laurel, which is much cultivated in that part where the Honey came from; in all there were 26 various specimens.

The Second Paper was on the Grenier Mobile, or revolving granary, the invention of M. Vallery, a French Engineer, by Thos. Birmingham. The object of this machine, a model of which was placed before the meeting, is to prevent fermentation and decomposition, which so frequently take place in Corn stored in the ordinary granary, as also to get rid of those troublesome and destructive insects, the weevil, mite, curculis, and moth. The revolving granary consists of a large wooden cylinder, the size of which is regulated by the quantity of Corn to be stored; the interior is lined with wire gauze for the admission of air, and has eight radial compartments for storing the Corn; the axis on which the granary revolves is hollow, and acts as a ventilating tube by means of a fan working at one end; one end of the cylinder is furnished with a circular rack, into which works a pinion attached to a handle, by which motion is given to the machine. Neither mildew nor rust can be formed; the weevils and other insects are destroyed, the Corn is sifted and kept free from dust and dirt, all damage from rats and other vermin is prevented. It undergoes no injury, as in being turned over by the shovel the quality of the grain is found to be materially improved, even if gathered under unfavourable circumstances of the weather. It has been successfully introduced into different parts of France.

Reviews.

Agricultural Chemistry. By G. Cox. London, 1844. 12mo.

The object of this little book is to enable practical men to establish or refute the opinions of others more, in other words, to make chemists of farmers, and teach them how to analyse soils and plants. Farmers have no time to perform chemical analyses, and even if they had, their analyses would be of very little use to them; for without much practice it is impossible to perform minute chemical inquiries, so as to obtain trustworthy results. The book is rather carelessly written, containing a number of strange statements and questionable facts, which we fear are more likely to mislead than to instruct. It is published as a companion to a portable laboratory, or test-chest, sold by the author.

Miscellaneous.

Dignity of Labour.—I have faith in labour, and I see the goodness of God in placing us in a world where labour alone can keep us alive. I would not change, if I could, our subjection to physical laws, our exposure to hunger and cold, and the necessity of constant conflict with the material world. I would not, if I could, so temper the elements that they should forbear into us only grateful sensations, that the earth should mate vegetation so exuberant as to anticipate every want, and the minerals so ductile as to offer no resistance to our strength or skill. Such a world would make a contemptible race. Man owes his growth, his energy, chiefly to that stirring of the will, that conflict with difficulty which we call effort. Easy, pleasant work does not make robust minds, does not give men such a consciousness of their powers, does not train to endurance, to perseverance, to steady force of will—that force without which all other acquisitions avail nothing.—*Channing.*

CALENDAR OF OPERATIONS

For the ensuing Week.

I.—HOTHOUSE, CONSERVATORIES, &c.

Succession occupants in their own plants, are often at a loss to know how dry or how moist a house should be when either stocks recommended by Gardeners or in Calendars, and the reasons can hardly be explained without the use of a hygrometer. In general terms we would keep all plant-houses dry in winter; but this only means the opposite of our summer treatment, and not total dryness, for no plant-house, except, perhaps, [illegible] plants, could be quite dry for any length of time without [illegible] through their frosty weather, when strong [illegible] the plants in this house will be much benefited by a gleam of sunshine early in the day; but during this month this is seldom done. And for the next six weeks more [illegible] water at the roots than at any other season. Those valuable Chrysanthemums, Justicias, Vincas, and other [illegible] now in bloom for the purpose of decorating rooms and conservatories, will find Cuphea Melvilla a good addition to them, the scarlet flowers it throws at any time between May and Christmas, according to the time at which it is pruned; a succession of large specimens, pruned closely and trained like Kennedyas or handsome pyramids.—*E. H.*

II.—FLOWER GARDEN AND SHRUBBERIES.

Out-door Operations.

The subject of the winter decoration of the flower-garden was carefully discussed in this Paper on page 707, 1843, that it is unnecessary for us to do more at this time than refer the reader to it, where he will find lists of plants, and every necessary information. An arrangement of this kind gives a garden a highly interesting appearance through the dull months of winter, and the only objection that can be urged against it is, that where beds are cultivated they cannot be managed so conveniently as if the beds were unoccupied. This, however, might be obviated by growing both the shrubs and bulbs in pots; but it is very questionable whether the latter would be so well grown as if planted in the open soil. Keep the ground as neat and clean as possible; and roll the walks and Grass as frequently as the weather will admit of your doing so.—*W. P. A.*

III.—FLORISTS' FLOWERS.

Auriculas will still require well looking after; all dead or yellow leaves must be gently shpped off, taking care not to wound the stem; the top soil must be frequently moved, and if there should be any appearance of bad drainage, the soil must be carefully turned out, keeping the ball entire, and more broken pot added. During rainy weather the lights of the frame must be kept on, but tilted behind, and a free circulation of air amongst the pots must be insured by raising the frame a few inches from the ground. Should any decayed leaves be thrown up, pull off the pots as soon as found, as they happen to be heart bounds. It is well to tilt the stages regularly. *Tulips.*—This is certainly rather an awkward time for bulbs, and especially those which were at all diseased when planted. Beds ought to be well rounded in the middle, to allow the free escape of all superfluous moisture, and the dressing most likely to be lately had an ample of. *Carnations.*—We know of a few extra fine seedlings, which will, we think, not prove "genus of the first water" Several have been exhibited, and in addition showing (which we think to be the best way of proving the merits of a seedling flower), they have been such varieties as Ely's Jolly Dragoon, Hunter's Patriarch, Ely's Lady Ely, &c., and this too when the old flowers were in a fine state. The results have surprised many of our friends, being completely out of season, for however cautious we ought to be in giving an opinion on flowers only once seen, still, from the splendid blooms which have come under our notice we are led to judge favourably of them. Carnations to name will require shifting into small pots, should the plants not be well established by the end of the month. Keep the plants up as well as you can, and if the leaves become spotted, the diseased parts should be carefully removed, and the plants replaced away from the general mass of foliage. *Pinks.*—Pinks that have made long straggling shoots may now be cut close, leaving a joint to lay the ground, and hoops should be placed over the choicest beds, that protection may be given in the event of sudden frosty weather, as they are apt to decay after excessive rain. *Polyanthuses.*—Proceed

IV.—FLORISTS' FLOWERS.

Pinetums.—Fine weather has made the work of potting of Pines so simple and free from risk, that till I recollect that many still grow them Pines with the least attention to the necessary materials alone, I fancy that all that is necessary to be said about Pines for the next few months might be put into a very few lines, and thus the almost unavoidable repetition that has to be made in this part of the Calendar is prevented. The Pines in houses heated by pipes or flues can easily be kept in that state of moderate growth which is found to answer all the best from dull winter, with all its suffering from the effects of the present damp and cloudy weather; as during the day a slight addition to the heat can be made, so as to allow air to be given to a sufficient amount, and during cold nights, when the means of heating them dying not leave, it will be necessary to keep the heat up a little higher in mild weather, in order to be prepared for any sudden depression of the external temperature, and to be enabled to give air daily for a short time at the top lights. This will prevent the plants from drawing and keep the atmosphere sweet. Be careful not to give much water, which is injurious to the roots at this season.

Peaches.—Vines in pots or boxes started in the beginning of October should now be swelling fast. The temperature be 55° to 60° by night, and 5° to 10° by day, with fire-heat, and from 60° to 65° with sun-heat. Syringe twice a day. Vineries which are expected to produce ripe fruit by the end of April, should be closed now, and it is convenient to have no fire to heat, and the air taken in through the border of the house; it will be the most genial means of exciting the buds. Keep temperature of from 50° to 55° when the weather is mild, and some degrees lower when the weather is cold.

Pines.—Get the late house put into the same state of temperature as the others. Where it happens that fruit trees have been placed in the pine pit that was forced last season, and the trees in the ground-house are in good condition, it will be well to exchange the order of succession, so as to give them the most genial warmth that can be made as soon as possible. Pot suckers in small size, and start them in pots and bark now, and if they can have a slight bottom-heat the Suns will swell more freely and uniformly. Let the temperature at night be about 60°, with sun-heat, when such is necessary, as will be sufficient. Syringe often, to hasten the swelling of the buds.—*E. F.*

V. HARDY FRUIT AND KITCHEN-GARDEN.

Grafting.—Few things are more interesting than this visitation, to those who delight to see their trees healthy, and producing good fruit in time. At this season for planting, or preparing for it, considerable attention should be given to the pruning of hardy as well as tender trees in all cases where the situation is not the most favourable. In addition to examining the trees of kinds suited to different localities, so often given in answer to correspondents, the planter should take the trouble of ascertaining what sorts have been in circumstances similar to his own. Canker owes its origin chiefly to three sources:—Planting too deep—the result of which is, that the roots are supplied with more moisture than is necessary, and the heat and sunlight of the plant are not sufficient to give ripeness and firmness of texture to the young wood; or from the roots getting into an unfavourable soil—that furnishes the trees with vitiated juices; or from the climate of the situation being too cold, or the season too dry and sunless to permit the healthy action of the plant. Some young trees that I planted very carefully on hillocks suffered considerably last season,

[illegible] Nov. 14, 1844, to the Observation Garden, Greenwich.

STEPHENSON Law CO. 81, Bucklersbury, London, and 17, New Park-street, Southwark, Manufacturers and Constructors of the Improved CONICAL and PORTABLE SYPHON or IMPERIAL BOILERS, respectfully solicit the attention of intending Horticulturists to their much approved method of applying the Flue system to Pinery, Peach-house, &c., by which atmospheric heat, as well as bottom heat, is secured at any required degree without the aid of flues, &c. &c. We have also to state that the Boilers supplied by us to our friends they are now making with the Improved Syphon, by which the cost is reduced [illegible] are now known, scarcely require attendance, and to those who have not seen them in operation, we beg to say that they may be forwarded as well to the Country as to London, and that we have [illegible] Gentlemen throughout the kingdom, and [illegible] to refer to them for the [illegible] that we have erected in their Gardens, Conservatories, &c. We beg to inform the Trade that we have commenced business in New Park-street, Southwark, for the construction of Horticultural Buildings, in which we hope to merit the [illegible] we have been favoured with by the Nobility and Gentry, and that the same may be obtained upon the most advantageous terms.

Conservatories, &c. of Iron or Wood, erected upon the most ornamental designs. Greenhouses, Hothouses, Pits, and Garden Frames, Wire Work, &c. &c.

The Agricultural Gazette.

SATURDAY, NOVEMBER 16, 1844.

THE present is the season during which most of our Farmers' Clubs Annual Reports are published. When they are well-compiled, new publications are more useful. The hard-earned, and often dear-bought experience of practical men is well worth attention and study; the resolutions of Farmers' Clubs on the various topics of Agricultural interest which have been discussed by them during the year, certainly deserve publication at the end of it.

It should, however, be remembered by those who have the charge of these compilations, that opinions on points of farm management, however fairly deducible from well-established facts, are rarely of extensive accuracy. This will appear to any one in the habit of attending Farmers' Club Meetings, from the acknowledged agricultural skill and success of many who differ widely in their views on some of the simplest matters connected with their business. The same effects will not follow the operation of the same cause, unless it encounter similar circumstances; and the causes which the farmer puts in action are influenced so much by soil and climate, both of which are notoriously variable in this country, that the great variety of opinion to be met with on the practical details of farming is not to be wondered at. All this we think should be considered by those who undertake the preparation of these Annual Reports, because it appears to us likely to influence a method of greatly increasing their value.

In another column of this day's Paper, we have referred to the necessity of combining with accounts of agricultural practice, statements of the circumstances under which it occurs. The propriety of so doing is indeed sufficiently obvious from what has been already said; and the suggestion applies with no less pertinency to the publication of opinions as expressed in the resolutions of Farmers' Clubs—opinions of which agricultural practice is just the embodiment. In reading a Report of a Farmers' Club, packed to which there was such a statement—one descriptive of the climate, soil, and general agricultural character of the district to which it referred—any person would be able to judge of the applicability to his own case, of the opinions therein expressed, and he would hazard no loss by attempts to act upon them, under adverse circumstances.

Doubtless, the primary object of Farmers' Clubs is, with each, the agricultural improvement of its own locality; and with this object in view, in their Annual Reports, and they are calculated to effect it, their present isolation is a necessary consequence of unexplained differences of opinion—differences which would be satisfactorily accounted for by the circumstantial appendix we are recommending.

Next to the publication, for the benefit of second and third year's farming, of what is found to be profitable practice in the best cultivated districts, it should be the object of Farmers' Clubs to exhibit the details of high management in the scientific man. Unquestionable Agriculture is capable of great improvement by the application of it to scientific principles, which cannot be done by people ignorant of farming; and it needs but little consideration to see that these accounts of soil, climate, and other circumstances affecting the practice of farmers, will render the differences of opinion existing among them instructive instead of puzzling or perhaps disgusting, as they might otherwise be.

These remarks, which we hope will receive the notice of SECRETARIES OF FARMERS' CLUBS, are introductory to a request which we have now to make to them, and perhaps our readers will kindly assist us in pushing their attention to it. It is our desire to be as far as possible the organ of these Societies, and to publish the facts, opinions, and views advanced by them. We should feel greatly obliged to their Secretaries if they would forward to us information on the following points:—The name and locality of the Society, its object, its times of meeting, and the subjects, if they have been fixed upon, for discussion during the ensuing year, and a report of discussions during the past year. If to such information statements were added of the climate, elevation, soil, and general agricultural character of the several districts, we should be enabled to obtain that clear and to appreciate the opinions indicated by the mass of information which would be accumulated.

Such an attempt to centralise the numerous but unconnected efforts which are now making in the cause of agricultural improvement, if it were successful, would probably be useful.

ANOMALIES OF AGRICULTURE.—CHAP. II.

(Continued from page 738.)

THAT he who will have most dealings, and be brought most into contact with Nature, should of all men be taught most about her, would seem an axiom; and he who is not ambitious of the character of "a powerful demonstrator of undisputed facts," might be well content to leave it as it stands, and not waste his own or his readers' time by enforcing or attempting to illustrate what seems self-evident. But in this motley crowd of life we daily find that what is Truism to one man is Paradox to another. And though the generality of our readers might at once admit the proposition, the fact is, that those whom we are most anxious to reach, and who are, if they only knew it, the most deeply interested in the matter, are *not readers at all;* and we are thus placed in the same category with the sign-post which in giving minute "directions for passing the ford" concluded with an "N. B.—Them as can't read had better go round by the bridge." Here is our difficulty; here is the leading and glaring "anomaly" indeed, of the "most ancient of the arts;" that the artists—seven tenths of them—do not read at all; and do not only believe, negatively, that no reading in the world could teach them one iota about their trade which they do not know already; but do also hold, positively, that there is some latent, poisonous, and pernicious quality about books, in its nature detrimental to the character of a "practical farmer." Nobody that has ever studied the phenomena of *mere* practical knowledge can wonder much at this. It is a fact universal and notorious in all the arts: the self-taught believes in no discoveries but his own: you cannot make him understand that the facts to be found in books are the concentrated and digested records of the experience of other men—as clever, as practical, as knowing as himself. The mere fact of its being *a book*—printed in harmless words instead of being deep-engraved in the damage to his pocket of failures and errors that he might have been warned against by the most ordinary instruction—is enough to make him turn an ear deaf as the deaf adder. He has heard his father or his grandfather say that *book-farming don't do;* he has never *learnt how to learn;* and want of early exercise leaves the mental muscles unused and rigid. He does not understand that Education does for the mind pretty much what Tanning does for leather; it renders it tractable and susceptible of impressions, prevents clumsiness and induration, prolongs and increases utility, and defers decay. Therefore is theirs the heavier task, and the more manfully to be undertaken and zealously carried out, who would fain see the *science* of Agriculture flourish in their own generation, and shed its irresistible and ameliorating influence upon cotemporary practice. The "gigantic strides" that this art, in common with every other, has already made, since Science has in some degree been allowed to take the helm, "small as they may be, compared with what might be done,"* afford ample earnest to warm the hope, even of the sanguine.

Few of the fables of Antiquity are more elegant in conception, more true in philosophy, than that which represents Minerva to have sprung from the brain of Jupiter, full-armed and full-grown. The Arts, it will be remembered, were presided over by Mercury, as ordinarily begotten a young cattle as ever Fancy pictured. Noted in youth for nothing but incorrigible mischief, he at last grows into a position of subordinate service, and made to fetch and carry, and there it ends. But the Goddess of Wisdom and Science, the offspring of a higher and nobler species of generation, "full of grace and manly beauty, perfect form, and perfect emotion," is ever sprightly and immature, passes on the same from century to century, ever improving, ever young, ever improved. To Science one day is as a thousand years; analytical truth revealing itself before her eye, soon assumes the form and proportion of synthetical truth. She collects inductively, the scattered and detached *facts* furnished in the rough by the practice and experience of thousands; she arranges and classifies them into "distinct and successful series," forming, numerically and productively one from the other; and the theorist assumes the clear and symmetrical outline of a living creation of lofty texture, tangible by reason, and palpable to faith. Be the subject-matter what it may, the result is in every human heart the same. Be it Navigation upon the sea, or Agriculture upon the land; be it the mind-

* Baron Stanley's speech at the recent meeting of the Liverpool Agricultural Association.

ing of an army of the effects of the progress of a force; or the mind prepared by a comprehensive and scientific knowledge of its task will ever bear the intensely vivid conviction that all opposing the practice of such a Science is "fighting against God." A short knowledge of results, of which the [illegible] and plausible quarter had unassisted, founded on the latest experiments and ingenious reasonings, [illegible] deep seen in our own day, a more memorable evidence of this, than in the delivery of Mr. Pusey's lectures, two years ago, before the Royal Agricultural College, of the first occasion on which the [illegible] of chemistry, in the physiology of assimilation and nutrition, and the causes of animal heat, were made matter of full and applied information to the Agriculturist, a sensation was [illegible] the whispered exclamation of [illegible] and intelligent farmers, just behind us (the [illegible] on hearing their own hard-earned facts brought home to them face to face, from a source so new to [illegible]. A man, who on awaking in the morning should find a mushroom sprung up on his floor, would not stare at it with more inexplicable amazement than they did on the lights of Modern Professor who stood before them. The same and worthy of all commendation. On the one hand were the stout yeomen of England, [illegible] every description of soil: the pastures of Northampton and Leicester, the chalky downs of Buckinghamshire and Kent, the new and the old red sandstone of Warwickshire and Hereford, the clays of Oxfordshire, and the shaly hills of the Gloucestershire Cotswolds, and a dozen other different soils had there each their stanch representative. On the other hand, supported and surrounded by a band of Nature's own, as well as of Society's Aristocracy, stood the young and learned chemist—the student of a minister-science—modestly conscious of the possession of knowledge which required but connexion to be valued, application to be proved. "What in the wide world can he tell us about hitting beans?" was the unveiled expression of many an incredulous face, the burthen of many a side-whisper. "It would be presumptuous," said the lecturer, "in any scientific man, however exalted his rank in science, to undertake to instruct an [illegible] village such as this, or to recommend alterations in the practice of an art, which he has learnt in the closet and not in the field. But it may be permitted, even to the most humble cultivator of science, to examine the practice which you yourselves have perfected, and to point out the laws of nature upon which that practice depends." And as the youthful philosopher proceeded to lay bare, in the clearest and most intelligible language, the recent discoveries in physiology, which he had himself the proud task of translating into our own language, the look of distrust and the smile of incredulity vanished: the vital and obvious interest of the subject at once arrested every eye and every tongue. If there was a heart there—and many there were—that beat with enthusiasm in the cause of Science, that was indeed a moment of pure and disinterested gratification. From auditors as unexpected as they were beyond suspicion for [illegible] scientific fidelity, he announced and explained their own most treasured maxims of economical and successful feeding," deduced and eliminated as the natural and necessary results of ascertained chemical causes. True it was, that many of the important results there advertised, were well known to many present as matter of the most advanced and skilful practice of the farmyard. But why was it that the more conscious they were of the practical truth of his deductions, the more the hearers were riveted, and the lecturer applauded? Because he showed them, with the fact which they did know, the why and the wherefore which they did *not* know; because he exhibited as a patent and apparent result tangible to reason and to argument, that which was before wrapped in the mystery of a mere arbitrary and isolated *fact;* thereby opening a vista of future application of the same principles to analogous cases. With [illegible] it was heard stated as a sure and incontestable result of chemical principles that warmth and shelter were a quantitative equivalent for a certain and considerable portion of food: and why? for a reason as simple as it is beautiful: that the bodily heat of animals is the result of combustion—not material, but actual, proceeding in the lungs without intermission during life, and derived from its universal cause, the union of oxygen with carbon; the former obtained from the atmosphere by the act of breathing; the latter supplied by the food through the organs of digestion to the blood, and brought into contact with the atmospheric air in the lungs: that a manifest consequence, the greater the amount of food consumed in just proportion to the defence of the animal against external cold, the greater the resulting demand upon the provender for the purposes of nutrition.

It would be [illegible] our purpose to advert even to a tithe of the facts brought to light or explained, in the course of these invaluable lectures; but we cannot forbear to refer to one more as illustrating the applicability of experimental Science, even to the most ordinary and familiar economy of the farmyard. It had been frequently observed, and is so to this day by dairy-farmers, that the cheese made from the milk of cattle "soiled up" there out of [illegible] quality, to that from the same animals when pastured; whilst the milk, cream, and butter, are greater in quantity, and equal in quality. Now Chemistry explains to us that the production of *caseine* (the principle of cheese) is favoured, and indeed only perfectly performed when the animal is in motion; that in fact its peculiar quality depends upon the exhaustion

* On the Application of Physiology to the Breeding and Rearing of Cattle.

by exciting of a certain portion of the animal economy which is a state of perfection would all contribute to the lacteal secretion. [illegible] during the very week in which we write, a query is addressed to the Editor of a contemporary Agricultural Paper, asking for an explanation of the observed deterioration of the cheese from stall-fed cattle. A very slight acquaintance with organic Chemistry would have rendered, as indeed it has long ago done, this otherwise inexplicable phenomenon; and have at once decided the dairy-farmer, whose object was the manufacture of cheese, upon the adoption of a different system of treatment of the animal to that pursued for the purpose of milk and butter.

We have adverted to these cases, not for their own sakes, or facts, because we conceive them to be familiar to most of our readers, but merely as instances in proof of the successful application of some of the most recent and important discoveries of modern Science to the art of the Agriculturist. It will be our future object to point out, in more technical detail, the particular sciences applicable to each department of the farm, with the more especial purpose of exhibiting those [illegible] of culture which have kept in a state of [illegible] and empiricism the first, unfortunately and [illegible] of human arts; believing, as we do, that its grateful susceptibility of the highest energies, has been overlooked only from its being, under the Wisest Dispensation, not entirely inaccessible to the lowest development of human intellect.—*C. W.*

CULTIVATION OF WHEAT ON THE SAME LAND IN SUCCESSIVE YEARS.

(Continued from p. 704.)

Having detailed the general results of the experiment, I beg to offer the following remarks upon some points in it, which seem to me to require a little elucidation.

I consider the success of this experiment to be in a great measure owing to the use of *soluble* silica and magnesia, because, although there is an abundance of silica in the soil, my first crop showed very miserable results, the earth being ill-fed and poor, and the straw soft and discoloured, although this year 1842 was, in this district, very favourable for Wheat, the month of August being singularly fine and warm; but when I combined the nitrate of soda with the sulphate of magnesia, as in experiment No. 3 in 1843, but still more when I combined it with the silicate of soda, as in No. 3 of that year, the straw became strong, firm, and bright as need be desired, and this is very much as both these salts are combined with nitrate of soda, common salt, and gypsum. I have not only good and bright straw, but also an abundant crop of Wheat, [illegible]

With respect to ploughing early it may be as well to state that the land had not been tilled for many years; and although in a dilapidated state, showed a deficiency of lime on analysis. The soil is a strong loam, on a brick clay, probably in which there is little or no lime, although the stony clays which form the subsoil for a great part of the district abound in it, containing from 20 to 30 per cent. of carbonate of lime. I had always believed that lime was used in great excess in this neighbourhood, and [illegible] that its good qualities were overrated inasmuch as it does not enter into the composition of the plant, except in very minute proportions; but last winter I saw a paper (by Mr. Briggs, of Thrunton) on the possibility of growing Wheat on the same land year after year, in which the utility of lime in preventing mildew was incidentally touched upon. I also saw Liebig's Lecture, explaining the action of quick-lime in liberating potash from the clay, and then I considered it very important to ascertain the proper quantity to be applied. The quantity required to decompose the phosphate of iron was not great; and, assuming Liebig's theory of the action in liberating the potash to be true, it seemed to me that in excessive dressings would permanently impoverish the land soon, supposing that the crop required 400 lbs. of potash, and an enormous dressing was applied, say 1600 lbs., what became of the 1200 lbs. which did not enter into the composition of the plant? Would it lie dormant in the land for ever? Would it be washed down the drains by the first heavy shower? Perhaps the above calculation will also afford a reason for its beneficial action in the experiment just detailed; it will, by supposition, be remembered, that 400 lbs. potash which may be liberated from the clay by lapse of time, [illegible] that by any means that only the quantity of potash required by the crop was washed down the drains, and [illegible] permanently exhausted. I believe that the [illegible] necessary. This opinion is [illegible] neighbourhood, which [illegible] opinion is prevalent that the more lime [illegible] better it is for the land, and where it is [illegible] ten or twelve tons to the acre at [illegible]

I have stated above, that the [illegible] to a small portion of the field [illegible] drought in April. The season [illegible] a good thing may be [illegible] improper time; for, although it produced a [illegible] effect, as the plant immediately [illegible] there was but little moisture in the land [illegible] thoroughly, and thus enable the plants [illegible] until the rain came, about the end of June, when [illegible] Wheat had been in flower some time; but the [illegible] was then so great that all the plants there [illegible] stalks (from the roots), which were in flower when the Wheat was cut; and it was then found that they had not only impoverished the plants, but had prevented the grain from ripening. This was the case not only in the [illegible] field, but in several fields also, where the chemical manure was applied, and the sowing in of the [illegible] to [illegible] every [illegible]

When the field was mown, it was thought desirable to cover one part of it with [illegible] and the other with [illegible] between the [illegible] the latter stimulating effect [illegible] more rapidly [illegible] Peruvian guano [illegible] the [illegible] which [illegible] the Wheat was just shooting [illegible] [illegible] application the experiment [illegible] which [illegible] application [illegible] [illegible] the [illegible] which [illegible] the object of the experiment. It is true, no bad effects followed the application, similar to those produced by the misapplication of the chemical manure in dry weather; yet, if soluble salts, like the latter, did not find sufficient moisture in the ground when applied in April, there is reason to suppose that the former would not do so when applied in May.

I regret the failure of the experiment without any manure, as I think the result would have shown satisfactorily that the land is so far from being impoverished by this system of cropping, that it is improving every year. I think, however, that this is shown by the produce of the land manured with guano alone. In the first year's experiment, the produce from guano alone was 27 bushels per acre; and both straw and Wheat were very indifferent in quality. This year, the produce from guano alone is 42½ bushels; and although neither straw nor Wheat are so good as upon the adjoining lands, they are both very much better than they were in 1842.

It will be observed, that the result from the unsubsoiled portion is very good; and, if nothing more were said about it, people would be led to conclude that there was no advantage in subsoiling. But this, in my opinion, would be a great mistake; for, to say nothing of the advantage which the unsubsoiled portion would derive from the drainage which it received from the subsoiling on each side of it, I found, when the field was ploughed up this autumn, that, whilst the unsubsoiled portion was stiff and heavy, the subsoiled part was comparatively friable and loose, like a garden, and will, I expect, show its superiority in the succeeding crops.

It must be borne in mind, in reading these experiments, that we have here one of the most unfavourable climates in the kingdom for growing Wheat, from the excessive quantity of rain that falls,—three times more rain falling annually in the north of Lancashire than at York; and this, no doubt, is very prejudicial to the success of such a series of experiments as I have been detailing.

It has been objected to these experiments, that, allowing all to have been done which is here detailed, it leads to no important conclusion; for, although it may be practicable to grow Wheat every year, in a small field like the one experimented on, it is not so on a large scale. But the objectors should remember, that there is not the seed of a single weed sowed with the manure; and, therefore, if the land is thoroughly cleaned, and kept so, by hoeing the crop in the spring, it will require very little labour to fit it for another. But I shall be better able to speak on this head next harvest, having sowed Wheat on an Oat stubble, with one ploughing. It is said there are no weeds in Chinese husbandry! and is they can eradicate them completely, so may we, if we adopt the same methods, and follow them up as perseveringly.

Again, admitting that it is not practicable to grow Wheat on the same land every year on a large scale, yet, if we can double the crop in those years in which we do grow it, by the application of chemical manures (and the same manures are applicable to all cereal crops), will not that be a conclusion worth arriving at? That it is possible to do so is, I think sufficiently shown by the results which I have obtained. What, then, may we expect when these experiments are infinitely multiplied and varied, under the superintendence of skilful and experienced men, who will devote their whole time and attention to the subject? Will raising the average produce from 25 to 50 bushels per acre be the utmost limit to which improvement can be carried? I believe not.

In conclusion, I would urge on all owners and occupiers of land, the importance of devoting a few acres to agricultural experiments. I think there can be no doubt that, if these are carefully and [illegible] made, and followed up for [illegible] years, that we shall have ample [illegible] for our guidance. The Chamberlains [illegible] shall be so far from needing [illegible] we shall be [illegible] [illegible] [illegible]

SELECTIONS OF EAST LOTHIAN HUSBANDRY.

Continuation of Turnip culture and system of agricultural improvement in East Lothian, extracted from the Introduction of Turnip husbandry, which was, it appears, partially introduced about the year 1760. The extent of rental now paid in the county is stated: But from the effects of judicious drainage on the soil, and the employment of additional manures, its present production, formerly considered to be surpassed by any other district in the kingdom, is greatly increased, and with a degree of economy, scarcely to be surpassed by any other district in the kingdom.

There are several variations both of the Swedish and common Turnip in general cultivation of the former species, the purple top kind is almost entirely and chiefly grown; and of the latter the Dale's, Big bill, Green-top Yellow, White Globe, &c. are the kinds generally cultivated.

As the greater portion of the soil is naturally unsuited to Turnips, much labour and attention are necessarily bestowed on the preparation of the land. The first ploughing is given immediately after the labours of the harvest, and the Wheat-stubble, Beans, and Potatoes, are concluded in which state the land remains until the spring. Corn crops have been sown, and the Potatoes planted, when it receives a second furrow, sometimes in a contrary direction to the previous one, but more frequently along the ridges resembling the former furrows. It is then repeatedly harrowed, rolled, and grubbed in various directions for the purpose of pulverising the soil, and of dragging to the surface, and disengaging from the intermediate clods of earth, the roots of Couch-grass and other weeds, which are carefully gathered into heaps and carted off to the most convenient corner of the field, or elsewhere as subsequently formed into a compost with quicklime. A third ploughing is then bestowed in a direction traversing the last one, and the other operations of harrowing, rolling, grubbing and weed-gathering are repeated, as before. The land is generally ploughed once more, and the subsidiary operations again repeated, after which it is in most cases in a suitable condition for being formed into drills; but as the great objects aimed at in preparing land for Turnips are the minute pulverisation of the soil, and the thorough eradication of weeds, these different operations must be persevered in till these purposes are attained. During this preparatory tillage much attention is necessarily paid to the state of the surface. Should it happen, as it not uncommonly does, in a drought, the furrows closely follow the plough in order to catch the land in a particular state between wet and dry, when it readily crumbles down. The roller is applied in succession to the harrow, for the double purpose of further reducing the clods and of preventing the evaporation of the moisture in the soil. This is a part of the process particularly attended to. Another point regarded as equally important is, that the land should never be ploughed or otherwise worked while in a wet state, unless under peculiar circumstances. As already intimated, [illegible] interposed in preparing the land in many cases for Turnips in wet weather, while in drought, when the moisture is so effectually worked out of the soil before it can be brought to the requisite degree of pulverisation, that small seeds, as those of the Turnip, cannot possibly germinate in such an unfavourable bed, till it is raised by copious rains. With the view of surmounting the difficulty experienced in reducing strong adhesive clay soils to a suitable consistency, even when the land is ploughed for that crop a thorough autumn tillage, the drills being formed and the dung carried in the usual manner, by which state it remains until the proper period for sowing the seed arrives, when the soil is usually found to be in a friable pulverised state from exposure to the winter's frosts. Several farmers, however, consider it a fitting that the crust of mouldering stiff clay land in autumn is beneficial, since much moisture is sometimes lost by the pulverising of the yard, and pointed that from the land lying in loose ridges, the succeeding Wheat crop [illegible] Beans crop must be [illegible] ridges.

[illegible] formed in the manner described in the case of Beans, the [illegible] which have remained [illegible] is formed by the operation of the plough [illegible] one direction, and [illegible] manner as in sowing [illegible] the seed is covered from the [illegible] until the manure is ploughed [illegible] visable, previous to the [illegible] 25 to 27 inches in the [illegible]

The [illegible] Swedish Turnips [illegible] Turnips [illegible] Swedish Turnips [illegible] Turnips [illegible] Swedish Turnips [illegible] Turnips

removing them. The following method is adopted at Studleigh, a place famous for growing Carrots of fine quality. The operator sits astride of the row, grasping each tightly as near the crown as possible, and holding the knife in the same hand, he then takes the body of the Carrot in the other hand, with the knuckle held downward; the Carrot is then sharply turned over the back of the hand with a little practice, the green part, which separates neatly from the root, leaving a mark cut on only. The Carrots are stated to keep better than when the green is left on, and the operation is performed in about half the time.—*Dibbler.*

Dibbling.—Many years ago a description was given in the *Farmers' Journal* of a method of dibbling Wheat, practised in Sussex (I think). The dibble consisted of an iron cone of 3 inches in length, jointed into a wooden handle with a T-head, and of such length that a man could use it without stooping. The workman walked backwards, having a dibble in each hand, making a double row of holes in each furrow-slice, and being followed by children, who dropped two grains in each hole. The weekly rent at that time, stated to be effective, a considerable saving of seed was made, and the treading of the crop and children was thought an advantage. A simple implement of this kind is much more likely to answer the purpose, than the one described by Mr. W. Bartlett, which would be very likely to choak, if the land were moist, and would require a very level surface to work to advantage. I have used an implement like Mr. Bartlett's, for planting Mangold Wurzel, but I very much prefer the drill.—*Lusor.*

Rotation of Cropping.—Notwithstanding all that has been said on the necessity of changing the kind of plant grown on the same soil, as essential to good husbandry, yet there are some soils which seem to contain an inexhaustible supply of the pabulum required for the successful culture of one species. I am well acquainted with a small garden, which has been planted with Potatoes for the last 55 years, and has always borne good crops, and those of very prime quality. The crop just raised is after the rate of about 7 tons per acre, chiefly of Kidneys and China Oranges, neither of which varieties are great bearers, as compared with many others, and in quality they are equal to any I have ever tasted. I saw the produce of one plant of a few varieties, of which I am sure several of the tubers would weigh 1lbs. each. The soil is a marly loam, resting on the mountain-limestone. Of course, it has been liberally manured, from time to time, and has been once or twice trenched with lime, and occasionally trenched, as was the case last year. But what quality of certain soils to produce good crops of the same kind of plant, many years in succession, seems not to be at present known. It is not known that much of the alluvial district of Somersetshire, which is capable of bearing good crops of Wheat year after year, with undiminished fertility, I have been informed, by good authority, that 25 successive crops of Wheat have been taken from the same field, near Exeter, none of which were less than 30 bushels per acre, and some considerably more.—*Lusor.*

Grass Land.—I occupy some meadows in Hertfordshire that would well lay; they produce a coarse Grass. The middle management for years past has been to mow twice a year, watered afterwards with cattle and sheep. I have found an addition of any dung ever having been put upon them. My land of late has been somewhat improved by superficial subsoil-draining, and I intend in this and the succeeding year to drain the whole afresh with pipes, and also roll, rolling with a heavy roller to fill up the pits and holes made by a succession of years by the feet of the cattle; but though the tile-draining may, two or three years hence, begin to tell, what do you recommend in the way of surface-draining? Every dent of a sheep's foot becomes a dish, which the first shower of rain fills with water, and it thus remains a little pond. I keep no bulls; the herd is continued in the usual manner, and calves are substituted in the shape of young and stable-feeding from a dairy; the aftermath is fed off by the stock of my neighbours, who drive the cattle to bull. Cooking-shipping. I have deservedly puzzled by my reading the above question and part of your Paper, and by the practical advice which it bears. It does not suit me to break up pasture lands (in which are ornamental timber trees) of my freehold estate to plant or keep stock. I wish some of your correspondents (who are to hand, and give us some observations on) the question there are many in my situation who would be equally well supply, though I hope the following letter may be a bit to deal with. The land was drained, and planted my Grass growing till very late, under the obligation till August, and the principal part of my crop was produced of third-heads the more appetising, as it is said time to mow, and, I fear, in many cases to cold, is there any chance of gradually extirpating this weed without breaking up the pasture? The nature of the root is known, and, after all, the plan of pulling it up displeases. Vitriol is where easily applied, and sowing fresh seed, be of any use?—*Rockbeare.*

Acorns for Pigs.—Some care is necessary to preserve when pigs feed upon them, for otherwise they will be subject to a distemper; to prevent which, the best way is to moisten with Peas or Beans with water, and sprinkle over some antimony pounded and sifted, or a little powdered brimstone; if this be repeated two or three times a week, for one or two weeks, it will effectually preserve them from the disorder; or if the Acorns be collected and prepared in the following manner:—Dig a hole in the ground, in this let the Acorns be put, well moistened with water, in which a handful or two of common salt has been dissolved: in a few days they will begin to heat and ferment; preserve them therefore attentively, and when they have made a shoot about two inches long, take them out of the hole and spread them to dry on a barn floor, and in a day or two they will be fit to give the pigs. This matter must, however, be attended to, for if the Acorns they must not have their many glutinous coats twisted a dangerous accumulation of heat; consequently the same must be watched, and if they appear to heat they must be spread abroad again. Acorns, when ripe, will keep for a long time in a dry place, if they are not suffered to heat.—*Delta.*

Dibbling Wheat.—It is objected to dibbling Wheat, that labourers are not to be trusted in evenly dropping the seed. Perhaps the object might be better obtained by sowing the seed in drills, and thinning it out in the spring, when the weaker plants might be drawn. But I must insist that dibbling or drilling at 9 inches is neither scientific nor good husbandry: the rows should be at least from 18 to 24 inches asunder. I am firmly persuaded that at about that distance the produce both of Corn and straw will exceed in weight Corn sown at any other distance; it has also the advantage of giving a fallow, and will in the stirring of the intervals give much employment, at a time of the year when the poor are much out of work. How much better than factory work for poor children!—*J. M. Geodesse.*

Guano.—Is it (as some suppose) the dung of birds or a fossil earth? Its being found in such immense quantities in different parts of the world, renders it almost impossible to believe that it is the former. It appears by a late No. of the *Times*, that the number of vessels now waiting to be loaded will bring to this country more than 100,000 tons; add to this the same quantity now on the different provinces of Peru, according to the accounts given by Pentagh and Prescott, and the immense quantity in those two last work, under the article of Guano, where it appears that considerable doubt exists as to its origin, and disposed to believe that naturalists are incontestably correct that it is a fossil earth. Time for answer.—*Z.*

Farmers' Clubs.—At the last Caledonian meeting of this Society, an interesting discussion ensued on the question appointed for the evening—namely, What are the best Modes of Applying Guano as a Manure to the different kinds of Crops reared in the County of Inverness? The experiments on this subject has not been of more than that of two years, but it has been quite satisfactory and encouraging so far as it has gone. Mr. Sutherland defended thereby muck and farm-yard manure system, as opposed to the introduction of foreign compounds and manures; but this afforded an opportunity to several gentlemen to show that guano is not meant to supersede the old mode of dressing, but to supplement it where a deficiency of farm-yard manure is not to be had, or where it cannot be easily carried; and that guano can be obtained and applied as a supplement to the dung-hill at the time of the expense of the home-made article. Mr. Mackintosh stated, that but for guano the potato-crop at all of it right till this season; Mr. Rhind, Dalcross, said he had never seen a finer crop of potatoes where it had been tried, although the quantity; and several other gentlemen testified to the fact that these effects did not immediately terminate for one season, but continued for the second year's crop. Mr. Sutherland, however, on the scourging nature of the crop, even after it has been laid down, still in the quantity of its elements which they may [illegible] Mr. Rhind stated that although he [illegible] for the [illegible] [illegible] [illegible]

[illegible]

[illegible]

[illegible] made to our readers for their experiments upon CROCUSES during the past season, have been replied from some valuable correspondents, especially Mr. Grey, of Dilston, and the Rev. Mr. Bates. These we shall publish before long; but we again take the liberty of mentioning the subject, and repeating our earnest request that details of experiments may be forwarded to us. We are sure that their value will be much increased, if, instead of being published independently of each other, they are brought into one point of view; for so they are most likely to be productive of public benefit.

At this is a good time of the year for sowing [illegible], and as we believe that a larger quantity than usual has been saved this season, we shall extract at length from our Paris friend his fifth chapter, entitled "*Mode de Propagation.*"

"Tulips may be increased in two different ways—by seed and by offsets. It is ascertained by experience, that any given variety of Tulip will not reproduce itself by its seeds; but, on the contrary, many will be originated, differing wholly from each other, thus giving amateurs an opportunity of raising new and improved sorts, which they term Breeders.

"To accomplish this with a greater degree of certainty, they increase their chances of success by only sowing seed of first-rate varieties, and especially those the bottom of whose petals is of unsullied purity; as I find that Breeders thus originated sooner develop their proper colours than those which are the produce of inferior sorts.

"When the ripeness of the Tulip seed, where the flower has bloomed in a full exposure, is indicated by the opening of the capsule, it is cut off a few inches below the head, and placed in a very dry situation, in order to insure its perfect maturity. This being accomplished, the seeds are taken out, and should be sown about the middle of October in a bed of well-prepared earth, which has been passed through a coarse sieve, and covered about the eighth of an inch in depth with soil of a fine and light texture, which will allow the free vegetation of the seeds, without incrusting or becoming hard. The beds must be protected from sharp frosts by covering them with leaves, or with mats, and likewise kept perfectly free from weeds. If these necessary precautions are attended to, the Tulips will come up towards the end of February. From the size of a small pea, in the first year, the roots will increase considerably during the two following seasons; and each time when the leaves fade, I spread over my seedlings about an inch in thickness of similarly prepared soil to that with which the seed was covered, being satisfied that from the loss of time, and the greater extent of land they will occupy, by taking them up in the second year, and replanting them in the usual plan, to allow them to remain till they have made their third growth. I do not like my seeds with that time, and in a few days after they attain their full size much sooner when treated in this manner; especially if mild has been mixed with the lime-rubbish which has been subjected with good stable manure, or vegetable soil.

"When they are taken in the course of [illegible] they [illegible] on their first blooming, which will probably be in the fifth year. [illegible] these roots, they appear [illegible] the greatness of the [illegible] which the seed was planted, and the [illegible] soil. Others, however, not in [illegible] also gratifying, on the account [illegible] which were at first confused and indiscernible, will attain their proper character, and realize all the perfection of which they are susceptible.

Here we see at once [illegible] that we like to have [illegible] or become variegated in the course [illegible] these roots were [illegible] lives in hope that, although uncertain, it may come [illegible] now of the [illegible] [illegible] saving [illegible] shows the flower always in the [illegible] fantastic, with its numerous [illegible] and [illegible] certainly defy a bad break or strain in [illegible] florists say true, no matter [illegible] [illegible] fully of an inferior degree of quality to the old [illegible] [illegible] changed its colour from the self or breeder stock, [illegible] [illegible] produce [illegible] [illegible] get a flower broken from the same breeder as their neighbour, but while he is succeeding in obtaining good and well-marked blooms, they may never be [illegible] flower is fit to be seen; and, in fact, it will bear no comparison with the other. Getting the strains of good breaks is the grand secret in Tulip growing. Thus we have Brulante éclatante, and Beteral's Brulante éclatante, the last immeasurably superior to the former; also Ponceau tres Blanc, and Dutch Ponceau tres blanc, the latter a finer strain than the other. Again: Sir Sidney Smith, a feathered bizarre, is called Magnum Bonum, when from a clean break; and many others might be adduced to illustrate our position. We have seen and grown French Tulips, said to be very fine sorts, but really we must have grown them many years (if they do alter for the better) before they would have reached our standard of a fine flower.

In continuation, "From their first flowering, all those with bad shaped cups are discarded, also those with indented petals, or that are tinged with yellow; and a weak bending stem is considered a serious defect.

"After the petals have fallen, the heads or capsules are cut off in order to strengthen the roots, which otherwise would be uselessly weakened by ripening their seeds."

"The side bulbs always reproduce flowers identical with those from which they derived their origin. Their period of blooming varies according to their size; it occasionally happens in the first year, and sometimes it will take six or seven years' growth before they flower. During the month of August, the bed must be prepared for their reception, and in September they must be planted from two to three or four inches apart, according to their size. Should their planting be deferred till November, it is very possible that many of the smaller ones will shrivel up and perish. When they are put into the ground or taken up, the same system is followed as in the main collection, so that all mistakes may be avoided, and by that means the amateur will be able to replace any bulbs which by accident or otherwise he may have lost in his choice or best beds."—*W.*

These directions, which are purely practical, and divested by the author of all theory, nevertheless, like all good cultivation, are entirely conformable to the laws of Vegetable Physiology. The same mode of management applies to all bulbs which naturally inhabit countries considerably warmer than our own; and, if it were applied to them with the skill and patience of a Tulip-grower, would have prevented the loss of many fine things, obtained at great cost, and of surpassing beauty, such, for instance, as the whole race of Calochortus.

TRAINING FOREST-TREES.

I OBSERVE in the *Chronicle* of Sept. 28, a successful refutation of what Dr. Thackeray does not recommend or practise respecting the training of forest trees. Mr. Billington states him to entertain the notion that "divesting a tree of its side-branches increases the weight or bulk of the timber in the trunk." Dr. Thackeray's system is not to divest the tree of its side-branches. That was the old plan, which lopped off all the side-branches, leaving a little tufty head, which was thereby encouraged to diverge into several branches of equal thickness; on the contrary, he selects a single stem in the leader, and gradually takes off such large branches as may interfere with and rival it. Mr. Billington next states that in a former [illegible] to him "shown, beyond a doubt, that Larches with undivided healthy branches [illegible] in girth equalled or even exceeded [illegible] having divested leaves and only a few [illegible] [illegible] Mr. Billington [illegible] [illegible] must be [illegible] [illegible] [illegible]

natural advantages. Now, if the circumstance of being situated partly on the northern brow, and partly on the summit of a bleak hill-side, where the soil consists of from 2½ to 3 inches of black bog or peat, or natural advantages, except the [illegible] possess such advantages in an ordinary degree; perhaps the unhealthy and unthriving plantations which join them in many parts are to be regarded as a further proof of the natural advantages which they possess. If their vigour of growth be now chiefly owing to the training which they have had, I confess I see no other rational way of accounting for it. There being no plantations anywhere near Dr. T.'s managed after the method advocated by Mr. B., I cannot speak to its relative merits in a comparative point of view; yet, from what is known of its tendencies, I feel warranted in saying, that if it had been adopted at Nerquis, the results would not have been quite so satisfactory.

Notwithstanding Mr. B.'s "protest against the pruning advocates," he agrees with them in first principles; and, indeed, most of his arguments go to support their views. Both parties seem to think that trees are supported chiefly from the atmosphere, through the agency of the leaves and branches, and that the vigour and growth of a tree is in proportion to the number of its side branches, and amount of its foliage. That foliage is essential to the healthy exercise of the vegetable functions, there cannot be a doubt, and care should be taken to preserve as much of it as is consistent with the purposes of artificial training; but it is opposed to all experience to maintain that the increase of timber in the trunk is best promoted by having a tree loaded with side-branches, or, as Mr. B. seems to think preferable, studded with spurs. One of the arguments used by Mr. B. in advocating such doctrines is, "that if you cut down a tree having numerous branches on one side, it will be seen that the concentric annual rings are much wider on the side having the numerous branches than on the other." Supposing such to be the case, it by no means follows that the side having the branches contains the greatest quantity of useful timber; for in such cases the apparent increase of timber is just the effect of the interruption of the continuity of the vegetable circulation, caused by the side-branches, and proves just effectually the error of Mr. B.'s system; for be it observed, that what he would have us cut off for good timber is just the ends of the branches, their twisted knots forming, as it were, knots, or distinct masses of wood within the body of the trunk, and rendering it useless for many purposes of carpentry. I think, then, there can be no advantage in any enlargement of the concentric annual layers, when produced by such means as I have described; and I feel pretty confident that those who have had most experience in converting timber will bear me out when I say that, in nine cases out of ten, that side of the tree on which there are most branches will be found to contain most good timber. In the artificial culture of wood the mere increase of timber is not the end in view. Fitness for use is quite compatible with great rapidity of growth; indeed, everybody knows that rapid growth produces coarseness of texture, and *vice versâ*. Therefore, in judging of the merits of a particular method of training young plantations, by an inspection of results, our opinions must not be founded altogether on the actual quantity of timber in the trees; while keeping in view vigour of growth, we must be satisfied that the means employed have been such as to produce that form of trunk which will, when it reaches maturity, yield the greatest return in the shape of clean sound timber of first texture.

The method of pruning by the fore-shortening of the lateral branches cannot, with any degree of propriety, be applied to the more valuable kinds of hard wood; for, in wood of this description, the natural tendency of fore-shortening is to give to the branch or limb so treated the character and disposition of the parent stem, and consequently a capacity for forming what is termed heart-wood; and it is well known that the twisting of the fibres produced by the side-branches is much greater in the case of trees containing heart-wood than in the case of those that have not reached to such an advanced stage of growth. Another circumstance worthy of notice is, that the twisting of the fibres, so injurious to the texture of the timber, begins where the branch originated, and not at its extremity. How improper, then, to follow a method of cultivation by encouraging branches intended to be eventually taken close to the trunk, and how necessary to remove these noxious shoots at an early stage of their growth!

The main object in pruning and training is to give a proper direction to its growth; and as the great object of the useful timber is contained in the body of the tree, we ought to endeavour to produce as great a length of trunk, in proportion to the branched top, as the habits of the tree will admit of. In short, to give to the tree that form which is most conducive to utility. That this may be effected by a judicious method of training, the results at Nerquis, [illegible] Mr. B.'s report would induce a person to suppose; but I would mention, and can use terms not in the slightest degree [illegible] but I would mention, and can use terms not in the slightest degree, that there is not the slightest appearance of anything having been overdone, and there is good reason to believe that the whole operations have been conducted with much caution, much care, and perhaps some niggardly-minded persons might be inclined to say with *too little cost*. It has sometimes occurred to me that this very great nicety of method which characterises every department of the management at Nerquis gives rise to the opinion which we sometimes hear expressed by [illegible] as have been accustomed to [illegible] overdone.

[illegible] one other [illegible] report which [illegible] Mr. B. appears to imagine that the trees at Nerquis have suffered [illegible] the want of proper thinning. To form [illegible] to the extent to which this operation [illegible] and, no reason must be had to the [illegible]. Although the woods [illegible] ainy their [illegible] others in the [illegible] yet [illegible] who has had [illegible] vation or [illegible] whose experience [illegible] to the rearing of timber on [illegible] valleys they appear to be [illegible] hardy trees who have experienced [illegible] the autumnal winds, where [illegible] plantations much exposed, [illegible] at Nerquis have been thinned [illegible] than their exposed situation seems to warrant. My own opinion is, that Dr. T. has nothing to regret on this head.

Mr. B. refers to a plantation belonging to W. O. Gore, Esq., M.P., in which it seems there is a noble Larch girthing at 4 feet from the ground 61 inches. We are told it was planted about 40 years ago, that it has had no pruning, but never was crowded." To meet this fact, which Mr. B. holds to be quite sufficient to show what might be accomplished by "proper management" — in a plantation at Craiglelo, near Ruthin, planted by Dr. T., and pruned according to the system practised at Nerquis, there are several such noble Larches; and although planted only 38 years ago, some of them girth at 4 feet from the ground 65 inches, and are from 65 to 70 feet in height. How justly might I too say, "This shows what may be done by proper management!"—*T. S. G., Flintshire.*

DISEASES OF PLANTS.—No. VI.

[Fungi.]

The subject of Galls belongs to Entomology, and a great variety have been figured in this Paper and traced home to their actual causes. It is mentioned here also because the forms, in many instances, have so close a resemblance to Fungi, and have been referred to them even by good botanists on a hasty and superficial inspection. For here, as in other branches of the creation, we observe somewhat of that wonderful analogy by which, in each distinct class or even division of natural productions, the same or extremely similar forms are repeated though accompanied by an organisation totally different; and it is this amongst other circumstances which makes it so absolutely necessary to examine into the intimate structure of the works of the creation, before venturing to pronounce upon their proper place in the system. In the case of Galls it is but a superficial examination which can possibly deceive, for even where the little grub which produced them has vanished, the total absence of all parts of fructification will at once decide the point. If, for instance, the cup-shaped Gall, which is so common on Oak leaves, be the object in question, any one who has once examined the hymenium of a Peziza, and observed the fructifying cells arranged vertically like the pile of velvet, with their row of eight mostly elliptic sporidia, cannot for a moment be deceived. One of the most puzzling Galls I have ever seen was sent by Mr. Macleay, from Cuba, on the leaf of some plant of the natural order Ochnaceæ, and has been figured in the "Transactions of the Linnean Society." In this case there is not merely an extraordinary development of the external cellular tissue, but the Gall is formed within the substance of the leaf, and after a time bursts through the cuticle and presents a little ovate body with a crenate border, and within this an operculum which is perforated [illegible] apparently [illegible] tool in the centre. [illegible] very close [illegible] [illegible] [illegible]

GUANO (GENUINE PERUVIAN & BOLIVIAN) ON SALE, BY THE ONLY LEGAL IMPORTERS, ANTONY GIBBS AND SONS, LONDON; Wm. J. MYERS AND CO., LIVERPOOL; And by their Agents, COTESWORTH, POWELL, AND PEYTON, LONDON; GIBBS, BRIGHT, & CO., LIVERPOOL. 47, Lime-street, Nov. 16, 1844.

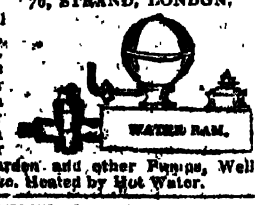
DR. HALLETT'S DRY SOLUBLE FERTILIZER, LIEBIG'S, &c., supplies those ingredients in which soils are deficient, for they are entirely composed of the Phosphates and other Salts of Minerals, and of Animal Matter, the most powerful fertilizers. They are mixed before the public as at first (see No. 88 of the Gardeners' Chronicle, &c.), a sort of silver find having found equal to 70l. per ton, and are sold at 10l. per ton in dry pulverulent mixture. They are applicable to all kinds of soils and to all crops: No. 1 for heavy top-dressing, &c. Corn, Grass, &c.; No. 2 for Roots in general stocks, each 4 cwts., a sufficient dressing for an Acre. Price of each 10l. per ton, or 10s. per cwt. DR. HALLETT'S CONCENTRATED LIQUID FERTILIZER is effected by the use of Ammoniacal Salts, and the Hall carries the most unmanageable, unsightly colours, and perfectly the seed of flowers, &c., in the shortest period, and in position six times the size, at 7s. 6d. per quart, which requires 32 gallons of water, to reduce it for use.

Agents for the above: Sandbach, Parker, & Co., Tunbridge-street; Mr. C. Shillitoe, 181, Holborn; Bedford-walk, Hammersmith; Messrs. Warner & Warner, 32, Cornhill; Hurst & M'Mullen, 6, Leadenhall-street; Wakefield, Country, Rock & Co., 24, St. Peter's Alley, Norfolk-street, Strand; and Watts, Norwich. Sundries—Mr. W. Ransom, Factorage, Ipswich—Messrs. Stancomb, Gloucestershire—Mr. Batterson, Retford, Nottinghamshire—Mr. Seward, Plymouth, Wilts—Mr. S. Kipps, Dorking, Surrey—Mr. D. C. Jackson, Whitehaven, Cumberland, Stockton, and Newcastle—Pace & Co. Dundee—Urquhart and Co. Further Responsible Agents wanted.

GYPSUM.—Farmers are advised by Chemists to use none but the Calcined Gypsum, the effects of which on Wheat are astonishing. The Pure Calcined Gypsum is a peculiarly strong quality, prepared for Mr. Oldacre, 63, Hatton Garden, London, at a lower price than dealers are charging for inferior Unpulverised Gypsum. Plaster of Paris for Builders equally low.—W. H. Treatise and Testimonials sent free on application.

DRAINING OF LAND.—THE WORKMAN'S DAVY LEVEL, invented by Mr. BAILEY DENTON, is made and sold, as approved of first, by Messrs. Jones, Opticians, 30, Lower Ranelagh, London-street, Pimlico.

PATENTED ROOFING FELT.



MCKIBBIN'S PATENT ROOFING FELT is particularly applicable as a substitute for Slate, Zinc, Tiles, Thatch, and other Articles used for Roofing, from its Economy, Durability, and Lightness. It is quite impervious to wet and damp, resists the heat of the sun, and is a bad conductor of heat or cold. Besides the economy in repairs, the timber where it is used may be so light as to save its whole expense. It requires no other coping, and prevention to printed directions may be applied by a common labourer. It is free from breakage and contraction, like tiles, and requires neither painting nor coating. It is now in very general use for Roofing Houses, Verandahs, Sheds, Warehouses, Ropeworks, Railway Stations, Icehouses, &c. &c., and for protecting Plants, covering Garden Frames, Corn, and Hay Ricks, the top and sides of Sheep-folds; and to Emigrants it provides a cheap, warm, durable, and portable Roof.

This improved Roofing Felt is much more durable than the common Felt, made in lengths, not being subject, like it or other Felt, to contribute longitudinally, to be stripped by storms; and being Lattined down at the overlaps only, the mat cannot percolate through the nail-holes.

Sold in sheets 38 inches by 20, at 5d. each (being less than 9s. 6d. per square of 100 feet).—Apply to H. C. Bowden, Agent to the Manufacturers, East India Chambers, Leadenhall-street, London.

RAMS FOR RAISING WATER WITHOUT LABOUR, where a fall can be obtained. FOUNTAIN BASINS IN IRON, &c. 70, STRAND, LONDON.

F. ROE having purchased all the Patterns of Basins, Jets, &c. formerly belonging to W. Rowley, Fountain Maker to the Royal Family, is enabled to offer the above article in iron, which will stand the Frost and last for ages. A Ram and Fountain Jets fixed on the premises for inspection. Every kind of Garden and other Pumps, Well Engines, Baths, &c. Houses, &c. Heated by Hot Water.

TO COLONISTS, EMIGRANTS, &c.—Mrs. MARY WEDLAKE, widow of the late THOMAS WEDLAKE, at 118, Fenchurch-street, City, informs Emigrants and others that she continues to manufacture those Agricultural Implements for which her late husband was so extensively patronised by the Settlers of South Australia, Van Diemen's Land, Swan River, New Zealand, and other British Colonies. The following articles, made in a very superior manner, are kept on sale at the London Warehouse, viz.:—

Patent Hay-making Machine	Flour-Mills—Bean-Mills
Dressing Machines	Patent Iron Ploughs, 20 sorts
Patent Chaff-cutting Machines	Subsoil Ploughs (Colonies
Oil-cake Crushers	Threshing Machines for the
Double action Turnip-cutters	Drills of all Kinds—Scarifiers
Railway Wheels	Vacuum Pumps.

Please to be particular in the address, Mary Wedlake, 118, Fenchurch-street, London.

H. WALKER'S NEEDLES (by Authority the "Queen's Own") have large eyes, easily threaded, (even by blind persons), and improved points, temper, and finish. Each paper is labelled with a likeness of Her Majesty or His Royal Highness Prince Albert in relief, on coloured grounds. Every quality of Needles, Fish-hooks, Hooks-and-eyes, Steel Pens, &c., for shipping. These Needles or Pens for the home trade are sent free by post, by any respectable dealer, on receipt of thirteen penny stamps for every shilling value.

H. Walker, Manufacturer to Her Majesty the Queen, No. 5 (late 20), Maiden-lane, Wood-street, London.

LEA AND PERRINS' WORCESTERSHIRE SAUCE.—Pronounced by Connoisseurs to be the Nectar of this County.

"Great Western Hotel, Birmingham, 1844.—The Chefs of the Great Western have been regularly supplied with Mr. Perrins's Worcestershire Sauce, which is an excellent accompaniment to every dish, from turtle to beef steak, game, poultry, or fish, to all of which it gives a delightful relish. I have much pleasure in recommending this excellent Sauce to Gentlemen visiting Birmingham, for its capital flavour, and as the best companion for the invalid for a voyage.

"One of the most piquant, invigorating, and wholesome and epicurean sauce in use, and I believe it is the favourite sauce to fish, flesh, fowl, and game, at most of the tables of the long-established favouring Nobility and Gentry."—Naval and Military Gazette, April 6, 1839.

Sold Wholesale by the Proprietors, Messrs. Lea and Perrins, Worcester; Messrs. Bland & Long, 20, Fleet-street, London; and the principal Oil and Italian Warehousemen in London, and Retail by the usual vendors of Sauces.

BY HER MAJESTY'S ROYAL LETTERS PATENT.

PETER FRAILY & SON, having had the honour of submitting to the Nobility, Gentry, and Agriculturists, as early as 1841, their NOVEL and ECONOMICAL SCREEN for COVERING FARM BUILDINGS, &c., which is now in general use, beg to call attention to their

ECONOMICAL COVER FOR HOTBEDS, FRAMES, AND SPAWN-HOUSES, which is light, durable, easy and economical in use, and is the invention of a practical Gardener, and is now in use at the

ROYAL HORTICULTURAL SOCIETY'S GARDENS, CHISWICK.

It can be had of any length, 32 inches wide, at 1d. per foot, super. A discount to the Trade.

THOMAS J. CROGGON, 8, Jugram-court, Fenchurch-st., London.

WHITNEY'S PATENT CLOTH for COVERING GREEN-HOUSES, CUCUMBER or MELON PITS, &c. This Cloth is made expressly for the purpose of applying Whitney's Composition upon, and is much more durable than any other material: when coated it is beautifully white and transparent. The perfect success of Whitney's Composition for all horticultural purposes cannot be more fully established than by stating, that, on the 1st of April last, a Black Hamburgh Vine was set in a border, the stem introduced into a house covered with Calico, and coated with Composition. On the 1st of Sept. a bunch of Grapes was cut weighing 18½ ounces, the fruit was finely coloured, and the flavour pronounced to be excellent. A sample was sent up to the Editor of the *Gardeners' Chronicle* for his inspection. The tree grew very luxuriantly, the foliage very fine, and the wood ripened exceedingly well. As a winter protection it is infinitely warmer than glass.

The PATENT CLOTH and COMPOSITION can be obtained of Messrs. Butler & Muckley, Covent Garden Market; Hurst & M'Mullen, Leadenhall Street; Warner & Warner, Cornhill; Barclay & Sons, Farringdon Street; and Hunnay & Co., Oxford Street.—Wholesale and Shipping Agent, Mr. Bailey, Wolverhampton.

FIDDLE and PRINCE ALBERT'S PATTERN PLATE.—A. B. SAVORY and SONS, Manufacturing Silversmiths, No. 14, Cornhill, opposite the Bank of England.—The best wrought SILVER SPOONS and FORKS, fiddle pattern, 7s. 2d. per ounce; the Prince Albert's pattern, 7s. 6d. per ounce. The articles may be had, lighter or heavier, at the same price per ounce:—

The Fiddle	oz.	s. d.	£ s. d.	Prince Albert's	oz.	s. d.	£ s. d.
12 Tbl. Spoons	20	at 7 6	7 10 0	12 Tbl. Spoons	40	at 7 6	15 0 0

1 pair Sugar-tongs			0 15 0	1 pair Sugar-tongs			1 5 0

Messrs. Savory and Sons recommend the Prince Albert's Pattern; it is very novel, and of unexampled beauty.

ELECTRO-PLATING AND GILDING.—OLD PLATED GOODS RESTORED and made equal to new by Messrs. ELKINGTON and Co.'s Patent Process. This process being carried on in London *only* by *Messrs. Elkington and Co.*, it is particularly requested that all goods may be forwarded direct to their Establishments, 22, Regent-street (corner of Jermyn-street), or 45, Moorgate-street, City. New goods Plated upon White Metal in great variety. Books of Prices and Drawings sent to all parts of the kingdom and abroad free.

STOOPING of the SHOULDERS and CONTRACTION of the CHEST are entirely prevented, and gently and effectually removed in Youth, and Ladies and Gentlemen, by the occasional use of the PATENT ST. JAMES'S CHEST EXPANDER, which is light, simple, easily employed outwardly or invisibly, without bands beneath the arms, uncomfortable constraint, or impediment to exercise. Sent per post, by Mr. A. Binyon, 49, Tavistock St., Strand, London, or full particulars on receiving a postage stamp.

PATENT ELECTRO-PLATED AND GILT ARTICLES in every variety, at the Establishments of the Patentees, ELKINGTON and Co., West End—22, Regent-street, corner of Jermyn-street; City—45, Moorgate-street. The Patent Electro processes being extensively adopted under their licence, the Patentees beg to state that they consider their own manufactures to be goods of a superior and warranted quality only, which are available bear their mark, "E. and Co." under a crown. Old articles replated and gilt.

THE LIBRARY OF TRAVEL.—VOLUME THE FIRST.

Just published, with 140 Woodcut Illustrations, price 5s. 6d. in cloth.

SYRIA and the HOLY LAND, their Scenery and their People, *Incidents of Travel, &c., from the best and most recent authorities.* By WALTER K. KELLY.

"Never was information more amusingly conveyed—never were the results of voluminous works of travel more spiritedly condensed than in this work. The execution is truly admirable. It reads like an original work instead of a compilation. The moral, social, physical, political, and geographical features of the East are well brought out, and the reader is at home with the Turk, the Arab, the Jew, the Druse, and the Maronite."—*Westminster Review*.

CHAPMAN and HALL, 186, Strand.

In one volume, cloth, price 5s. 6d.,

CHESS for BEGINNERS; in a Series of Progressive Lessons: shewing the most approved Methods of Beginning and Ending the Game, together with various Situations and Checkmates. By WILLIAM LEWIS. Second Edition. With 24 Diagrams printed in colours.

CHAPMAN and HALL, 186, Strand.

Order The Athenæum of any Bookseller or Newsman.

JOHNSON'S GARDENERS' ALMANACK for 1845, price 1s., illustrated with Woodcuts, will be published on NOVEMBER 21.

This Work commenced with the year 1844, and was so eagerly received by the public that it speedily attained the Eighth Edition. The plan of the Work, therefore, may be presumed to be generally known and approved of; and every effort has been made to render the forthcoming Number richer, if possible, than that of the preceding year. As it is intended to form a permanent and indexed record of matters interesting to the Landed Gentry and Cultivators of Gardens generally, a Ninth Edition has been printed expressly for the purpose of supplying Early persons who, commencing with 1845, may afterwards feel desirous of having the Work complete.

London: Printed for the Company of Stationers; and sold by G. GANNERELL, at their Hall, Ludgate-street.

SUBSCRIPTIONS

FOR THE

NATIONAL TESTIMONIAL

TO

MR. ROWLAND HILL,

AUTHOR OF THE PENNY POSTAGE,

WILL CLOSE ON THE 30TH OF NOVEMBER.

Of all the sources of income stated in the recently published Quarterly Returns of the Public Revenue, none exhibit *so large* a proportionate increase as the *Post Office*. On the year's net Revenue, the Customs have increased at the rate of about 10 per cent., the Excise 1¼ per cent., the Property Tax 2 per cent., while the *Post Office Revenue*, under its present nominal rate of a penny, has increased above 12½ per cent., and the increase on the quarter has been even as much as 25 per cent.

These cheering results show that (though the *plan of Penny Postage* is yet but *imperfectly tried*) the *complete restoration* of the Post Office Revenue to its amount before the Penny Postage was adopted is not an event far distant, if it be fully and honestly carried out; and the *City of London Mercantile Committee on Postage* desire to impress these satisfactory results most emphatically upon the Public, in announcing the *approaching close* of the National Testimonial to Mr. Rowland Hill. *All* parties are unanimous upon the great *moral* and *commercial* advantages of the *Penny Postage*. Its expediency as a *financial* step has been the *sole* ground of question; but now, even this *can scarcely be doubted*; for, let it be remembered, that the Old Postage Revenue had been absolutely *stationary* for twenty years,—retrogressive, in fact, if we consider the increase of population, education, and commerce during the period. The change which Penny Postage has effected, is to make the *Post Office Revenue* the *most buoyant* source of National Income, bidding fair to become more profitable than it has ever been. The Committee, therefore, call upon the Public to reward, with suitable gratitude, the Author of this great and triumphant measure.

The Committee have the satisfaction to announce that the Subscriptions, headed by the chiefs of political parties and of commercial wealth, already reach 10,000*l.*; but 16,000*l.* cannot be held to be a sufficient *national* reward for such *national* services. The Committee therefore urge upon the *nation at least to double* this sum. If every letter-writer, for only a single week, would pay a twopenny instead of a penny rate for his letters, the amount, and more, would be raised. In proportion as the public show their gratitude to Mr. Hill, so they strengthen the chances for the complete adoption of his plan, *now but partially carried out*. Its perfection will bring greatly-increased convenience to themselves, and increased advantage to the Post Office Revenue.

Never have the services of any *Public Benefactor* been *requited* as Mr. Hill's have been. Quitting a *permanent* situation *for a temporary* public engagement, to carry out his plan, Mr. Hill's services, whilst his plan was yet not carried out, were dispensed with, and he received the following acknowledgments of his merits, and—*nothing more*:—

"I gladly avail myself," writes the present Chancellor of the Exchequer, "of the opportunity of expressing my sense of the satisfactory manner in which, during my tenure of office, you have discharged the several duties which have been from time to time committed to you." "I entertain," writes Sir Robert Peel (who has also subscribed 10*l.* to the Testimonial), "a due sense of the motives by which your conduct, in respect to Post-Office arrangements, has been actuated, and of the zeal and fidelity with which you have discharged the duties committed to you."—Mr. Trevelyan, on behalf of the Lords of the Treasury, writes thus:—"I am also commanded by their Lordships to take this opportunity of stating, that they consider it due to you, on the termination of your engagement with the Government, to express to you the approbation with which they have regarded your zealous exertions in the execution of the duties which have been intrusted to you; and how materially the efficiency of the Post Office arrangements has been promoted by the care and intelligence evinced by you in the consideration of the various important questions which have been referred to you."

Under these circumstances the Committee call upon the *Public* to come forward with due generosity, and reward Mr. Hill themselves, as the *unrequited Inventor* of the *great measure of Penny Postage*—a measure which has opened the blessings of free correspondence to the Teacher of Religion, the Man of Science and Literature, the Merchant and Trader, and the *whole British Family*, especially the *poorest* and most *defenceless* portion of it;—a measure which is the *greatest boon* conferred in modern times on *all the social interests* of the *civilised world*; for Penny Postage is spreading its influence throughout Europe and reaching even Russia. The Committee rely on the gratitude of their countrymen, and feel sure that this, their last appeal, will not be made in vain.

(Signed) GEO. LARPENT, Chairman.

Subscription Cards, and every information, &c., may be obtained on application to the Secretary, Mr. GEORGE WANBEY, Solicitor, 3, Moorgate-street, London.

FASTOLFF RASPBERRY.

J. Bell begs to refer the readers of the *Gardeners' Chronicle* to his Advertisement this week of the Great Yarmouth Horticultural Establishment, Broadgate Street, Whitefriars, Exchange Street, Norwich.

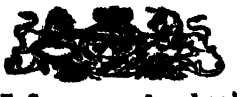
THE TRUE FASTOLFF RASPBERRY.

PATRONISED BY HER MOST GRACIOUS MAJESTY THE QUEEN, HIS GRACE THE DUKE OF RUTLAND, HIS GRACE THE DUKE OF MARLBOROUGH, THE EARL OF HARRINGTON, THE EARL OF LIVERPOOL, THE LORD BISHOP OF NORWICH, LORD VISCOUNT LORTON, LORD [illegible], and Sir [illegible] as well as by the HORTICULTURAL SOCIETY OF [illegible].

YOUELL AND CO. beg to announce they are again able to supply fine canes of the above truly excellent variety, unequalled for the size of its fruit and richness of flavour, as follow:—

			£	s.	d.
[illegible] containing	100 Canes	.	2	0	0
"	50 "	.	1	1	0
"	25 "	.	0	12	0

For [illegible] of the above, see Youell & Co.'s Advertisement [illegible].



Youell and Co. feel it due to themselves to state that a spurious kind was offered for sale by other parties last season, under the title of "Fastolff Raspberry," the same having no pretensions to the genuine variety; and to obviate a repetition of the like they have appointed the following Nurserymen and Seedsmen as their Agents for the sale of it, at whose establishments may be seen engravings of the Fruit:—Bury St. Edmunds—Mr. R. Pettit; Canterbury—Mr. W. Masters; Carlisle—Messrs. Little and Ballantyne; Chichester—Messrs. Newman and Co.; Cliff Vale, near Leek, Staffordshire—Mr. F. Fox; Cork—Messrs. Haycroft; Doncaster—Mrs. Milan, Seed-shop; Dundee—Messrs. Urquhart and Son; Durham—Messrs. Hancock and Sons; Edinburgh—Messrs. Peter Lawson and Son; Fulham—Messrs. Whitley and Orbell; Glasgow—Messrs. Dryadale and Co.; Lincoln—Mr. W. Featherope; Halifax—Mr. W. Thorp; Jersey—Mr. R. Saunders; Leeds—Messrs. Ely and Son, Rothwell Haigh; London—Messrs. Pleasance and Son, No. 9, Mansion House-street, and Messrs. Noble, No. 153, Fleet-street; Liverpool—Mr. James Cuthbert, 13, Clayton-square; Manchester—Mr. H. D. Cormack; Nottingham—Mr. J. F. Wood, The Coppice; Peterborough—Mr. John White; Penzance—Mr. J. Fox; Plymouth—Mr. W. E. Rendle; Sheffield—Messrs. Fisher, Holmes, and Co.; Southampton—Mr. James Ingram; Stafford—Mr. J. Sandy; Torquay—Mr. J. Morgan; Wakefield, Mr. W. Barratt; Waterford—Messrs. Fennessy and Son; Westerham, Kent—Mr. I. Cattell; Wexford—Mr. James Harper; York—Messrs. T. and I. Backhouse.

YOUELL'S CELEBRATED TOBOLSK RHUBARB, the earliest sort known; fine roots, fit for forcing, 12s. per dozen. For Particulars, see their Advertisement of Nov. 2.

Finest Imported DUTCH HYACINTHS, 6s., 12s., and 18s. per doz.; for Particulars of which, together with the Extensive and Select Collection of CARNATIONS, PICOTEES, and PINKS, see their Advertisement of Nov. 9.

Great Yarmouth Nursery, Nov. 21.

UNDER THE PATRONAGE OF HER MAJESTY.

J. G. WAITE, Seedsman, &c., 1 and 4 Eyre-street Hill, Hatton Garden, London, embraces the present opportunity of returning his best thanks for the very liberal support he has hitherto received, and to assure his friends that no exertion shall be wanting on his part to merit a continuance of their favours.

J. G. W. most respectfully informs the public that Seeds of every description (with the exception of Carrot) are unusually fine this season, and he will offer them at very low prices.

Waite's Queen of Dwarf Peas, per quart . . . 7s. 6d.
A splendid new variety, growing only 1 foot high, producing a larger pod than any of the same habit, the seed is quite distinct from all others, and larger than any Dwarf Pea in cultivation. It has been grown at the Royal Gardens at Frogmore, and approved of as a new variety, and also at Her Majesty's table, for its superior flavour.
Cuthill's Black Spine Cucumber, per packet of 100 seeds 5s. 6d.
Waite's Race Horse, do., 32 inches long, Black Spine, and wonderful bearer . . per packet of 20 seeds 5s. 6d.
True Beechwood Melon . . . of 25 do. 2s. 6d.
Pimelia spectabilis, new . . . of 5 do. 2s. 6d.

J. G. W.'s unrivalled [illegible] of Seeds will be ready at the end of the [illegible] and sent on application at 1 and 4, Eyre-street Hill, 1844.

[illegible] GREAT YARMOUTH NURSERY.

Youell [illegible] opportunity to [illegible] only at their [illegible] of them appear on the [illegible] Chronicle; and they [illegible] purchasers at whom they [illegible] been substituted by [illegible] "true variety."

Great Yarmouth [illegible] 1844.

F. GODFREY [illegible] of DWARF ROSES, [illegible] varieties of the Hybrid China, [illegible] &c., is offering them at the following [illegible]:—

100 Strong [illegible]	25s.
50 do.	15s.
24 do.	8s.

Guildford, Nov. 16, 1844.

NAPOLEONA IMPERIALIS.—A few Plants of this beautiful Shrub, lately described by Dr. Lindley, in the "Botanical Register," may be purchased, price Five Guineas each, by application to Messrs. Thos. Grimes and Co., the Secretaries to the Royal Agricultural Society of England, corner of Half Moon-street, Piccadilly, London.

THE TRUE FASTOLFF RASPBERRY.—In last week's *Gardeners' Chronicle* are two Advertisements issued by certain parties, offering for sale what they term "the Fastolff Raspberry." Upon referring to these Advertisements it will be found that one states it to have originated in the garden of Mr. Jary, of Burlingham, and the other in that of Mr. Lucas, of Filby; thus placing the correctness of their statements in a very questionable point of view. Mr. Rivers states that the fruit upon which Dr. Lindley pronounced his opinion was gathered in what he terms "the Filby garden." Youell and Co. beg to say that this assertion is utterly void of truth, and they regret Mr. Rivers should have lent his name to the publication of such.

As to the true origin of this valuable variety, Y. & Co. beg to say that they fully believe it originated in the garden of the late Rev. G. Lucas, of Little Ormesby Hall, in this county, and who was a most intimate and highly-valued friend of theirs (not the Rev. G. Lucas, of Filby), and where they had ample opportunities of making themselves thoroughly conversant with the variety they are sending out as the "True Fastolff Raspberry;" and since that period they have bestowed every care and attention in purchasing every cane of this Raspberry, and marking the same during the fruiting season, which is the only time when this variety is to be detected from several kinds grown in this locality, and called the "Filby Raspberry," "Seedling," &c. Y. and Co., at a cost of between 300l. and 400l., brought before the public the "True Fastolff Raspberry;" the demand it met with, the distinguished patronage it enjoys, and the many marks of approbation they have received for thus bringing into public notice a most valuable fruit, which would, until now, have remained in obscurity, and gratified the wishes of certain parties, and thus deprived the horticultural world (*pro tempore*) of so great an addition to their collection of fruits. Youell and Co. having purchased all the available stock of this Raspberry, knowing such to be correct, and rejecting many grown in this neighbourhood, which may, perchance, be palmed upon the public as the True Fastolff, &c., they again caution their friends that they cannot be held accountable for its answering the merits ascribed to it by them, unless purchased at the Great Yarmouth Nursery, or of their Agents, a list of whom appear on the advertising sheet of this day's *Gardeners' Chronicle*.

Great Yarmouth Nursery, Nov. 21, 1844.

KNAP-HILL NURSERY, NEAR BAGSHOT, SURREY.

HOSEA WATERER (Brother and Successor to the late Michael Waterer), respectfully begs to announce that the American Plants this year are remarkably well furnished with bloom; and with the other articles which are generally required for forcing, he has this season to offer very fine plants of the hardy Scarlet Rhododendrons. This Nursery has long been celebrated as containing the finest Collection of American Plants in the kingdom; independent of this, H. W. is a most extensive grower of Hardy Ornamental Trees and Shrubs, Roses, Forest and Fruit Trees; this may be inferred from the fact, that the Nursery extends over near 100 acres of land. The Knap-Hill Nursery is 2½ miles from the Woking station of the South Western Railway.

All letters intended for this Nursery must be addressed Knap-Hill, near Bagshot, Surrey.—Nov. 23, 1844.

PLANTING SEASON.

R. WHITE and Co. have to offer the following at very moderate rates, viz.:—PINUS MENZIESII, INSIGNIS, SPECTABILIS, GRANDIS, PONDEROSA, HARTWEGII, DOUGLASSII, DEODORA, 1 to 2 feet; EXCELSA, and many other rare sorts. Also strong Quickset, Beech, Birch, Oak, Maple, Spruce, Larch, and all kinds of forest-trees, Rhododendrons fine at 60s. per 100; A collection of Roses, comprising upwards of 700 of the most distinct and beautiful kinds, which have been carefully selected. In the Fruit Department there is a fine collection of Maiden and Trained Trees of Peach, Apricot, Nectarine, Pears, Apples, Cherries, &c., which includes all the fine kinds of Pears now in cultivation. Of Ornamental Shrubs, there is a fine healthy stock of all the finest kinds, and from the light nature of the soil in which they are grown, trees from this Nursery will be found to thrive remarkably well after transplanting. Geraniums, finest kinds, comprising—Beds of Ornament, Beauties, Lord Ebrington, Circassian, and good kinds, 24s. per doz. Hoosainee Melon, true, 2s. 6d. per packet, 6 seeds.

NEW AND SPLENDID RHODODENDRONS.

RHODODENDRON WILLIAMSONII. — This magnificent variety was forwarded for the opinion of Dr. Lindley and also of Mr. Glenny. Dr. Lindley (see *Gardeners' Chronicle* for May, 1844)—"*G. B. S.*—Your seedling makes a handsome and showy variety for the garden; the heads of the flowers are large, compact, rich in colour, and the foliage is very handsome." Mr. Glenny (see *Gardeners' Gazette* for May, 1844—"*G. B. S.*—If hardy, a very great acquisition. Also very large, bright rose, well spotted, and if bloomed in the open ground, a valuable addition to our hardy plants, for the foliage is as perfect as the flower."

RHODODENDRON INVICTUM.—A very detailing deep rosy crimson, very dark spots, a most distinct and superb variety, and blooms later than most of the hybrids, and quite hardy. The above two splendid hardy Rhododendrons now offered to the public were raised by Mr. Williamson, the Curator of the Birkhead Botanic Garden, where INVICTUM has bloomed for several years, and has drawn the admiration of all who have seen it. Price for the two, 42s.

Apply to F. Glenny, Nursery and Seedsman, Bluefield; W. and A. Gilbert, Market Drayton; or Messrs. Warner and Warner, 29, Cornhill, London, where paintings of the above may be seen.

[illegible] Pudsey, Yorkshire, Nov. 29

[illegible] BOOKS which have never before been offered to the public, and which are the most desirable ever put to bloom yet [illegible]

FLOWERS, Hilperton, Wilts, begs to call the attention of the admirers of this lovely tribe. He is well prepared to offer the above to a [illegible] At one trial will prove their superior strain [illegible] descriptive list post-free to any part of the kingdom.

W. has paid much attention to the growing of [illegible] for many years and feels proud to say [illegible] as, during blooming season, they be seen the selection from extensive beds for the past nine years' [illegible] which are models of Nature's best work.

Ranunculus Seed, in packets, 5s each.

GERANIUMS AT VERY LOW PRICES.

WM E RENDLE, having a large stock of the following sorts of GERANIUMS, is enabled to offer them at very low rates

*** A dozen will be forwarded on receipt of a Post-office order, including hamper, package, and carriage free to the Exeter terminus of the Great Western Railway

Black.]—10s per dozen, including package carriage, &c.—Lady Williams, Fascination, Thunderer Oberon, Favourite, Prince of Waterloo, Jessie, Count D Orsay, Lord Ebrington, Constellation, Leyinia, Cornish Gem, Attila, Duke of Cornwall, Eleanor, and Modesty.

Rose, &c.—12s per dozen, including package, carriage, &c.—Evelina, Gipsey, Witch, Hamlet, Cynthia, Aurora, Cronje, Lady Cotton Shrubland, Countess of Mount Edgcumbe, Full Midnight, Morning Star of the West, Portia, Jupiter, Lilt, guardsman, King John, Sultan, and Princess Royal (Lyne)

Scarlet.]—12s per dozen, including package, carriage, &c.—Camellia, Louis XV, Vice Admiral, Enchantress, Glory of the West, Ivanhoe, Pizzi, Queen of the Fairies, Grand Monarch, Alexander, Wildfire, Mabel, Prince Albert, Nymph, Bridegroom, and Rival.

All the plants are strong, healthy, and well established, and will be sent on receipt of the money, or free list of order

Station Road, Pudsey, Tuesday, Nov. 26, 1844

PLANTING SEASON.

W. ROUMIEU AND SON, Nurserymen, Contract Planters, & Landscape Gardeners, Southampton, beg respectfully to notify that their Nursery Stock is this season unusually fine, and from the extent of their grounds they are enabled to supply Forest Trees to any amount, and at the lowest prices. Specimen trees of Evergreens (if ordered in quantity) per [illegible] Oak, "Dormant," 10s per [illegible]

[illegible]	English	1	2	3 ft
[illegible]	Turkey	1	2	5 ft.
[illegible]	Spruce	1	2	6 ft
[illegible]	Larch	1	2	3 ft
[illegible]	Scotch	1	2	4 ft
[illegible]	Pinaster	1	2	2 ft
[illegible]	Pea Pine	1	2	3 ft

[illegible] Chesnut, 1yr., 15s } per
[illegible] Plane, 1 yr., 2s 2d } 1000.
[illegible] 2 yrs., 3s 6d

[illegible] for Shade or exposure to the sea, [illegible] per 1000.

Oak, the true "Durmast" of the New Forest (Quercus sessili flora), producing timber of the largest dimensions, and decidedly the most valuable species of the English Oak, 1 yr., [illegible] 2 yrs., 15s per 1000.

TRANSPLANTED.

Plants [illegible] of the various sizes may be had on application

[illegible]	Oak, "Dormant," 10s			
[illegible]	English	1	2	3 ft
[illegible]	Turkey	1	2	5 ft.
[illegible]	Spruce	1	2	6 ft
[illegible]	Larch	1	2	3 ft
[illegible]	Scotch	1	3	4 ft
[illegible]	Pinaster	1	2	2 ft
[illegible]	Pea Pine	1	2	3 ft

If [illegible] only one sort is ordered, a deduction from these prices will be made.

Prices per thousand for Transplanted

Rhododendron ponticum, 2 to 3 inches, 25s; 3 to 6 do. per 1000

Ditto, 2 to 3 inches, 40s to 50s per 1000; 4 to 6 inches, 60s to 80s. per 1000; 1 foot, 20s per 100

Hollands aquifolia, 40s per 1000. Cuttings are remarkably fond of the fruit of this plant, which is also a handsome flowering Evergreen.

Common Laburnum, 10s to 15s per 1000

Common Willow, 4 to 6 per 1000. (Best for Underwood)

[illegible] 50s per 1000 Broom, 10s per 1000.

[illegible] Quicks, transplanted, 4s per 100 Excellent forest embankment [illegible] Limerick, 5s per 100

[illegible] WILKINSON

A [illegible] Ornamental Trees of large growth, [illegible] for park, adapted for immediate effect

[illegible] Trees, well rooted 5s to 7½s per 100

[illegible] Cuttings of the Lucrative Poplar, 10s per 1000

A descriptive Catalogue sent on application Plants gratis, to remunerate for distant carriage —Wedenham, Nov 23, 1844

THE FILBY, or FASTOLFF RASPBERRY.—At the request of some gentlemen living in the neighbourhood of Yarmouth, T RIVERS begs to submit the history of this highly excellent Raspberry to the public. In the year 1814 Colonel Lucas, of Filby, a place lying between Mautich and Yarmouth, discovered a Raspberry plant growing under an old Laurel hedge in his garden. His attention was drawn to it, and he soon found it to be a superior and delicious variety, so that in a short time every other sort was ejected from his garden, and this alone cultivated. It was not however, till 1819 that he allowed his gardener to part with it who then gave canes to his neighbours, and by this means it got to be cultivated in Ormsby, Ormesby, and, in fact, in all the neighbourhood, under the name of the FILBY RASPBERRY, to the exclusion of all other sorts. It has latterly often been called the Ormsby Raspberry, from the Market Gardeners growing it in that parish. In Ormsby is an old castle in ruins, that formerly belonged to the Fastolff family: the latter name was given to the variety by Young and Co., when they first began to sell the canes. The fruit above which Dr Lindley pronounced his opinion was obtained for the Filby garden, now the property of the Rev. Charles Girdlestone, his heirs, and families the publication of the above facts, and has also published this Garden r to supply the genuine canes after this date to T. RIVERS only

Canes two years old, 4ds., per 100, or 6s. per score, carriage paid to London; Ostrich, for package, for small parcels, 6d., for large do., 9d. to 12s. 6d. Orders to any amount can be executed. Price lists gratis will be given on application

Sawbridgeworth, Herts, Nov. 26, 1844.

		Linnæan	8 P M

WHEN we, a few weeks since, invited the attention of our readers to some supposed cases of the TRANSMUTATION OF OATS, we were not aware that so many such instances were on record Thanks, however, to our correspondents, we have now before us several statements as to one kind of plant changing to another, so that the history seems more than ever to be worth following up. Not that we anticipate a confirmation of these stories, for they do appear most incredible, and contrary to the usual order of things, yet, as we have before observed, some very recent and most astounding instances of change, quite as great as that of Oats into Rye, have occurred, concerning which there cannot be a doubt, and therefore there is no knowing what more may be behind

Mr Darwin, who agrees with us that so curious a subject is well worth investigation, "even if it should prove to be only a history of error," points out a passage in Dr. J. Anderson's "Recreations," &c (vol. ii. p. 306) for the year 1800, where he remarks on an extract from a Dutch journal, in which it is said, that a countryman sowed Oats and cut them green three times, and that "in the ensuing spring only a few stalks not cut, any fresh shoots, and these were good Rye." Dr. Anderson attempts to explain this by supposing that seeds of both grains were in the ground, and that the Rye, from being the hardier plant, alone survived the winter; and he concludes by exclaiming, "What a bonfire it would make if all the books which record such experiments were burnt, at once!" But Dr. Anderson knew nothing of the modern facts above alluded to.

Another correspondent finds the following in the "Million of Facts," by Sir Richard Phillips, p. 153: "Barley in rainy seasons or years degenerates into Oats; and Oats in dry seasons change into Barley. These facts, noticed by Pliny, Galen, and Matthiolus, have been confirmed by the experiments of naturalists, &c. &c."

Of all these statements, however, which have been made from time to time, the most remarkable are those of "a Dr. Wiesenborn," which were published by the late Mr. Loudon in the "Magazine of Natural History," and which, while they astonished the gardening world, must have excited considerable

[illegible] made with more [illegible] garden, a bed of 12 feet square was [illegible] and pulverised, and sown about the middle of March, 1836, with picked Oats. The blade sprung not [illegible] tolerably well, and was thin, as the seed had suffered from frost in the preceding autumn. It was cut, for the first time, when part of it had already begun to form a shoot The second mowing took place in autumn. This year, the second of the experiment, the bed is covered with healthy Rye-stalks, though fewer in number than the Oat plants, which stood on the bed last year"

The other case is that of a Lieut-Col de Schauroth, who five years previously had found this experiment succeed seven times, and that in every case Rye had sprung from Oats, when the latter, during the first season, had been prevented forming stalks Col. de Schauroth had been averse to publish his observations, from his dislike to controversy, but as he was fully satisfied about the truth of the phænomenon, "he asked me," says Dr Wiesenborn, "to repeat the experiment, I delayed doing so till I could have an opportunity of sowing Oats on ground which had neither yielded a crop of Rye, nor had been manured with litter for a long time previously Three years ago, however, I ploughed up a paddock in which there had been nothing grown but Grass for the last 15 or 20 years It was planted with Potatoes for two years, and the third spring, sown with Oats and Lucerne, which were fed off by sheep, so that none of the Oat-plants could run to ear. During the severe spring of the present year, the greater part of the Oats were destroyed, but when the Lucerne had attained a sufficient size to be fed by sheep, it was found intermixed with a great many healthy Rye plants, just in ear It appears unnecessary that the Oats should be sown about midsummer day; and it is very natural that the Rye-plants should be fewer than those of the Oats, because all summer Corn is, in a great measure, destroyed during winter"

These statements were made in 1837. In the following year Dr Wiesenborn again brought the subject before the public, in the second volume of the "Magazine of Natural History" "With reference," he says, "to the transformation of Oats into Rye, this remarkable phenomenon has not only been verified by new experiments, but we have caused beds to be sown with Oats, in order that we may be able to convince disbelievers, by producing Rye stalks which have sprung from the crown that still shows the withered leaves of the Oat plant of the previous year. I repeat that this transformation does take place, if Oats are sown very late (about midsummer-day), and cut twice as green fodder before shooting into ear; the consequence of which is, that a considerable number of Oat plants do not die in the course of the winter, but are changed in the following spring into Rye, forming stalks which cannot be known from those of the finest winter Rye We must expect that this fact will be considered by many as a mere assertion, and there are others who are still in doubt about it, the latter, however, own that they either have not made the experiment, or have sown their Oats too early, and, therefore had cut them oftener than twice, in order to prevent their running to ear, whereby the plant loses the power of surviving the winter, and of being transformed into Rye I cannot notice such adversaries as reject the result without having put it to the test of experiment, or who rest their opposition on experiments that have not been conducted in the right manner. *I set any one sow Oats during the latter half of June, and the transformation in question will certainly take place!* The time of sowing the Oats did not formerly appear of paramount importance, nor was it believed that it could make any difference whether the Oats were cut more than twice; in consequence of which a few experiments have failed. Now, however, we must conclude, that if the transformation occasionally takes place with Oats that have been sown too early, that is merely an accident depending on a peculiar state of the weather, or other accidental circumstances; whereas the result is quite certain if the Oats are sown towards the end of June. If the soil is too dry about that time, one of the reporters on the subject, to the Agri. Soc of Coburg (Lieut. Donauer), concludes from an experiment he made in 1837, that one watering, so as to enable the Oats to germinate, may be recommended; although if this be done repeatedly, the high temperature of the season will cause the plants to grow so luxuriantly that it becomes necessary to cut them three times when about 1½ foot high, to prevent their forming their ear, whereby the object would be wholly or partially lost. If, however, among those who doubt this fact, there be found people who pity us because we print more to actual amusement than to science, we should almost feel inclined to pity them, whose self sufficiency has prevented them from thoroughly investigating an [illegible] phenomenon which was [illegible] Nor can we commend the discriminat[illegible] are unable to discover in the [illegible] both the preceding year's dry stubble, and [illegible] the Oats, and the fresh stalks and leaves of [illegible] which later form in May upon the crown [illegible] plant, and produce fine winter Rye. The Society must credit to itself for perseverance, in having struggled against the opinion of the public for several years, in order to establish a fact which no physiologist would believe, because people are always apt to confound the laws of Nature with those of their systems."

Such is the state of the case, as far as is at present known. We cannot conclude our relation of these strange stories better than in the words of Dr. Wiesenborn himself. "It is not," he says, "with a view of engaging anybody to believe the alleged transformation, that I call the attention of the English reader to the above observations, but merely from a wish to relate a curious phænomenon whose frequent recurrence can hardly be doubted, on account of the mass and respectability of the evidence now before the public, and the cause of which, for the same reason, it appears not altogether irrational to inquire into, by repeating the same experiment in various localities."

We wish we could persuade a few gardeners to bear these statements in mind, and to make the trial next year, when midsummer arrives It is a question much more likely to be answered satisfactorily in a garden than in a farm.

ON PRUNING FRUIT TREES.

As the pruning season is at hand, I beg to offer a few remarks on Pear pruning, more especially the new Flemish kinds, as also a brief account of their general management as pursued by me for the last eight or ten years.

It is notorious to all who are in any way conversant in gardening affairs, that by the old method of close spurring, the trees on walls became gradually clothed with their advance to age; this barrenness proceeding from the centre of the tree to the extremities, until at last some three or four hundred feet of walling would be occupied for the sake of a few dozens of Pears, hanging at the extremities of the shoots.

Now the loss of walling, which is itself is no trifle, was not all in this case. The tree had to undergo a thorough revision every year, at stated periods, not with any hope of inducing the tree to become in any way more prolific, but to keep up the decent appearance of the wall

The habits of the Pear being duly considered, and the circumstance of such limited powers of leaf, with unlimited powers of root, being taken into consideration, who could wonder at such results? A wall of trees treated in this way, if it could be placed on the ground in a horizontal position (with the trees attached), would be no bad representation of a coppice in miniature; and, indeed, the principal points of management bear no small resemblance. To excite the woody principle is the same result in both cases; but change the case with regard to the Hazel coppice, let the trees grow up free from the pruning knife, and consequently suffer the elaborating powers to reach or overtake the absorbing ones, and the result will be Nuts, instead of grate-wood or faggot-ties.

In the case of wall Pear-trees, an objection of a serious appearance seems to stand in the way: I mean the exclusion of light by suffering the tree to remain unpruned There is, however, no real difficulty in the affair, as I have proved by experience. The root must be limited—the power of making shoots placed under control It is well known that the absorbing powers of the Fig are so great in our humid climate, that all good cultivators take care to limit its roots, without which, it is in vain to expect success; and the leaf by this process being much reduced in size, the exclusion of light is by no means so great. Now the tender Flemish Pears are in precisely the same predicament as the Fig, if left uncontrolled at the root the elaboration of the tree, and fructifying sap is ever in arrears

In stating my practice I will begin with the young trees from grafts. I make it a rule to transplant them annually, if possible commencing with the young plant in the autumn succeeding the grafting season My object is to exchange tap roots for fibrous ones, and consequently prepare them for a system of complete root-control, the roughly ripened and short-jointed wood here the object to be obtained; and the next and important object with me is to prepare mounds of brick or stone on which to place them in their final destination.

The subsoil must of course be free from any lodgement of water, and if not naturally so, I of course introduce drainage The soil I use, and which seems to be the best adapted, as coupled with my shallow border system, is a strong and rather clayey loam from old pastures, which, if the pasture abound in soil, may be dug, turf, soil and all, about six inches in depth.

My platforms are about six feet square, and the fresh dug loam is roughly chopped, and tumbled in without farther ceremony; no manure or vegetable matter of any kind is mixed with it, and, indeed, it would be quite superfluous in my instance. The surface of my platforms, before I introduce the soil, is about nine inches below the general level, and the soil when filled in is one foot in depth, and consequently elevated three inches

...ing, and the ...ing, and the ...ing, and the

…in this communication I have sent… which were cut from a flow… plants belonging to Mr. Kingsmill, …Mountington. One is Vesta, and the other … The first, as will be seen, is a flower-producing … leaf; the second a leaf growing out of a flower. … also in Mr. K.'s houses, amongst several pro… of this kind, an unexpanded bloom, having small leaves in the place of sepals. This, I am told, may be considered extraordinary; but when it is observed that Mr. K. is enabled to continue the propagation of them throughout the winter by perpetuating a supply of the pigment essential to the production of carbonic acid, and consequently vigorous growth, with his ability of supplying the only agent upon which the development of the highest organs of plants mainly depends, namely, solar light; and as the power of this gradually becomes less at this time of the year, it is not very surprising that the plant, instead of coming at once to form the higher, and producing perhaps the lower organs, should exhibit traces of its former existence, of course where the influence of heat and light are considered, as in the case this is more likely to happen.—*W. Sherwood.*

Tile-draining.—My tank is made of wood, and covered with the tiles, similar to those used for roofing, and only reversed, as the inside is over the tiles as placed about 6 inches of sand, in which pots are plunged. I find that the tiles give out too much moisture and cause small plants to dislike it. I would not recommend the plan which I have used, although a heat-pipe to heat a tank, as proposed by one of your correspondents. The disadvantage is that in order to be kept up to a high temperature it requires a good deal of fuel, and to keep the temperature at 90°. Mr. Spencer, in Gardeners' Chronicle, states that attention to the furnace in 24 hours is sufficient; but with a moderate fire will not do. In the part of the pit [illegible] I have tried it, but things; but I should like a flow system, which should be put on the tiles to form a good drainage, and then about a foot [illegible] within the pit, and [illegible] fuel and [illegible] which I [illegible] Cumberland. The pit is [illegible] which [illegible] much moisture [illegible] the tank. The well-established and old plants will look well this autumn, for which the propagating [illegible] intended, evidently are not doing well.—*Gardener and Steward of the Redbreast.*—I had [illegible] of testing, in the most [illegible] the accuracy and fertility of the [illegible] known to how dire an ex… that [illegible] will go. Frequent as is the [illegible] hardly less so is it in the [illegible] of indeed members, although not [illegible] in weight, are scarcely [illegible] under the influence of the "green-[illegible]" the [illegible], I was in the garden, [illegible] a number of [illegible] with my favourite [illegible], which, although [illegible] have [illegible] succeeded in your columns) in a wild state, and in perfect liberty to roam [illegible] this little bird, to which we and my family a constant guest, sleeping in Marensecourt Park by night, and dropping in to breakfast at the mornings. I was [illegible] on the [illegible], holding a blackbeetle [illegible] in the middle, between my finger and [illegible], [illegible] to my pet coming for it as usual. [illegible] above the apex of my nose. He [illegible] for the [illegible], he quickly took his accustomed [illegible]. ...General Laborde is another fine compact flower, worthy ...
...attention. Those we have noticed were various conspicuous for their fine colour and freedom in blooming; but the whole collection is well worthy attention. The Camellias are looking remarkably well, and promise an abundance of bloom.

T. A. Phillips's, Esq., Thornfield.—There is in the Pine-stove at this place a Sierra Leone Pine-apple, which measures 19½ inches in circumference, and 11½ inches in length. This variety is said to attain here the same weight as the Montserrat and Jamaica. I presume that it will not weigh less than 8 or 9 lbs. It is planted out into the bed. This fine fruit is in my opinion much superior to one of a New Providence which I saw cut, and which weighed 11 lbs. 8 oz.; and I trust that those who have doubted the possibility of accomplishing such a result will not lose the opportunity of seeing it. Although large and well formed Pine-apples are often produced at Thornfield, yet this is not the result of wide planting; on the contrary, the plants are crowded even to excess. In a pit 23 feet in length and 7 feet in width, there are now growing 60 plants, from which Mr. Hamilton says that he will, in all probability, cut a second crop next year of 250 lbs. of fruit.—*R. H.*

Miscellaneous.

Borax in Bread—One of the means employed to give bread made of bad meal a good appearance, is borax. According to Duvills, the bakers use about 4 oz. of borax to 100 lbs. of flour. To detect the borax in the bread, a considerable quantity should be extracted with water, the filtered extract clarified by boiling with albumen, and strained; upon this concentrated sulphuric acid is added while stirring, and it is then placed aside. If borax is present, crystals of boracic acid separate, which are now readily detected by their well-known reactions.—*Chemical Gazette.*

Chinese Ice-houses.—The ice-houses around Ningpo, and especially on the banks of the river between that city and Chinhae, are beyond calculation. They are built above the ground, and generally upon a platform of earth raised so as to be above the level of the surrounding fields. Upon such a mound a bamboo frame is thrown, which is wall and closely thatched with paddy straw. The ice is collected in tanks or ponds, which the proprietors of the ice-houses take care to keep duly filled with water during the winter season. When the ice is of sufficient thickness they collect it; and, as it is brought in, each layer is covered with dry straw, and in this manner the ice is preserved during the whole summer. Each house has its own drain, to draw off the water formed by the melting of the ice. The article is not used in Ningpo for domestic consumption, but solely as an article of luxury, such drinks as wine of the month of cooling the beverage. ... —NEW FLOWER GARDEN AND GREENHOUSE PLANTS.

Gardeners' Chronicle.

I have been frequently upbraided during the autumn for not having mentioned some new plants which are likely to prove useful for flower-garden purposes; the opinion of country gardeners appearing to be that, because I occupy a post near town, I must of necessity see something among new plants which may do for bedding out. Verbenas abound, I imagine, will make an exceedingly fine bed, provided it can be depended to flower liberally; and as it seeds freely, there will be no difficulty in procuring plants. The plants should be planted out about the time of turning out, as it is from that period I should think it generally blooms. Pentas carnea is a pretty plant, which much is expected by some cultivators; but being from tropical Africa, it is very doubtful whether it will make a good bedding object in very warm and favourable situations. It is very readily propagated by cuttings. Eschscholtzia macrophylla, being yellow, will be useful, either for a large bed, or planted down for a small one; it will require a rather poor soil to make it flower profusely. Alona ericoides, a plant which will probably be better known as the new shrubby Nolana with double flowers, will make a fine bed, but of its culture I can say nothing at present. The dwarf Phloxes, of which we have now so nice a collection, will be much in demand next season; but the plants in which I place the greatest confidence for a new feature in the flower garden, are Mr. Girling's Petunias, and others which have been noticed during the season in this Paper; some of them are exceedingly beautiful.—*W. P. A.*

IV.—PINERIES, VINERIES, &c.

Fire-holes.—The roots of Vines cannot be allowed to stop growing for want of heat, without receiving injury. It appears that they cannot remain stationary, but must be either advancing in growth or decaying. Sufficient bottom heat should be maintained to keep them slowly advancing through; but the ... from 55° to 65° will be found to maintain the fruiting ... plants. If they be kept in steadily maintained, and ... roots kept rather dry than moist, they will be kept in a healthy state through the winter, which is a great desideratum ... growing.

Examine, in starting Vines by means of fermenting matter, ... within the house. A considerable proportion of leaves should ... mixed with the dung, to prevent the steam from the latter ... discolouring the rafters and shanking; or if the vapour is ... likely to be too strong, a thin covering of old mats will prevent ... injurious effects. Should the weather continue mild it ... will be necessary to open the ventilators, so that the temperature ... may not exceed 55° for the first eight or ten days. When some ... can be seen round the stems of the Vines by where the bedding ... will communicate, and keep the house moist, in order to prevent ... the stems from being dried up by the heat from the flues. In ... using manure to force Vines with fire-heat it is unnecessary to give ... air till the buds are ready to expand their first leaves. Syringing ... must be resorted to whenever the ... in red. ... If the roots are outside of the house, and there is the ... of one inside at command, ... sufficient to keep up the ... of which will be very evident ... the Vines inside.

Peach-house.—It is not uncommon to see many of the buds of healthy trees drop off in a dry withered state, just after the ... has commenced. I will not say the border ... too ... dry is the sole cause of this, but I believe it is often the cause. ... If the lights have remained on the house during the autumn, ... look to the state of the border, and give it a sufficient watering. ... Keep the shoots moist by the frequent use of the syringe; it ... will rarely be necessary to give air during sunshine at this ... season, till the blossoms are nearly expanding. Lay the outside ... border ... covered with litter.

Vines, Peaches, and Figs in Pots.—These should be plunged in old tan or leaves, either in an open shed or in some warm ... situation. Old leaves are ... for ... protecting the roots of plants in pots from frost. Set them ... ... or three inches above the rim of the pots, and covered over with litter or ... [illegible]

V.—EARLY FRUIT AND KITCHEN GARDEN.

Pruning and Training.—These operations in ... favourable weather ... [illegible] ... the trees were suitably ... [illegible] ... until the spring of winter shall have ... [illegible] ... of tardant trees should be cut in pretty ... [illegible] ... the leading shoots considerably short- ... [illegible] ... rather than quantity is aimed at; Gooseberries ... [illegible] ... in a similar manner, if the profusion of wood ... [illegible] ... ving the fruit produced chiefly on the young ... [illegible] ... the small spurs on wood of two or three years' ... Apples and Pears against walls should have their ... [illegible] ... kept as near the wall as possible, not only ... the height of the wall, and prevent the unsightliness ... long, rampant, overgrown shoots, but also the ... of ... sized, well-coloured fruit. Attention to this ... ... production of healthy trees when grown ... will furnish a good lesson on this subject. In the case of ... some of our best sorts of Pears, which have a tendency to form a ... blossom-buds at the end of short spurs of the previous year's ... growth, care should be taken to shorten in the young shoots, ... and, if long enough, to fasten them close to the wall. Peaches ... may be pruned much the same as Pears, only the best fruit is ... usually produced on wood of two or three years' growth, ... and ... to a little ... every season. ... Those ... [illegible] ... very apt ... to ... shoots too short, ... [illegible] ... Trees, especially ... young ones, ... [illegible] ... by the summer, and ... made to ... [illegible] ... Comparatively few ... will be ... [illegible] ... alternately with a shoot ... [illegible] ... the shoot; or if the ... [illegible] ... [illegible] ... [illegible]

native vegetation may be recorded as a later period in the spring. Where thin tiles had been placed on part of the border near the wall, for the radishes to rank, and keeping the border moist, they may be removed, the trowel then from being broken by frost or the performing various necessary operations; or if not considered too valuable, and if the draining was very defective, they might be bedded in clay, &c., to throw the water off the border. In extreme cases advantage might be taken of the very useful plan advised for Vine borders in the forcing department of the Calendar a fortnight ago

Shallots, Garlic, &c.—I generally find that these thrive best when planted about this season. The ground should be well trenched, and a place chosen where none of the Onion tribe had been grown for some time. Many failures arise from planting them too deep. They should merely be fixed on the surface, and then sprinkled over with a mixture of soot, lime, and ashes. The smaller variety is most prized by cooks generally; the large sort is easier grown and produces more abundantly, but its flavour is not reckoned so fine.

Peas and Beans.—Make a first sowing of Prince Albert Pea, and Mazagan Bean, and sow them or other approved sorts again about the beginning or middle of next month. Those sown now will be useful if the weather should be favourable and though they be cut down by frost it will only be the loss of the seed. Sow upon the breast of well-drained ridges, so that the young plants may be defended from east and north winds. Cover the seeds with chopped furze, Barley chaff or sharp sand, as a protection from mice.—*R.*

VII.—COTTAGERS' GARDENS

For those who are desirous of forming new plantations of Gooseberries and Currants, which should be done every six or seven years, young plants being found to produce more handsome fruit and also more plentifully than old ones, I would recommend from among the many varieties now cultivated, the following; viz., Yellow Sulphur, good and very early, but does not last long. Red Champagne, Taylor's Bright Venus, Pitmaston Green Gage, Red Warrington, Woodward's Whitesmith, Melling's Crown Bob, Harrow's Roaring Lion, and for preserving, the small Rough Red Of Currants, the Black Naples, Red and White Dutch and Knight's Large Red. In light soils, as soon as the present rainy weather shall have cleared off, and the ground become somewhat dry, the above may be planted with greater advantage than in spring. In preparing the ground let it be trenched to the depth of about two feet, thoroughly mixing with the surface spit a liberal allowance of manure or rich compost. About 5 feet square may be considered a proper distance at which the plants should stand in the rows. The pruning of Gooseberry and Currant bushes may now be proceeded with. Let the centre of the bushes be kept free and open, cutting clean off any strong shoots that rise from that part. Cut out all branches that cross one another, leaving the leading shoots about 10 inches apart, and tending at a kind inclining to the open space. All lateral twigs not required to form branches should be spurred in to a few buds. Black Currants require no pruning except thinning out the branches a little, when the bushes have become large and thick of wood. Plants in pots, &c. should not be watered in winter until they are quite dry, and then all the soil in the pots should be thoroughly wetted. If the pots are well drained, the soil will only retain a certain quantity of water, and if that quantity is not sufficient, a portion of the soil at the bottom—where the roots generally cling—will become too dry. The plants then linger for a time, and ultimately perish for want of sufficient moisture, and yet the soil may appear wet enough on the surface. All plants require this treatment during winter, whether evergreens or deciduous, whose roots require only to be stored in damp sand or light earth, when these are stored in a dry material they sometimes suffer too much.—*J. McH.*

State of the Weather near London for the week ending Nov 21, 1844, as observed at the Horticultural Garden, Chiswick

Nov	Barometer At 9	Max	Min	Thermometer Max	Min	Mean	Wind	Rain
Frid.	15	29.678	29.630	50	45	47.0	S.W.	—

The highest temperature during the above period was on the 7th 1834—the lowest was on the 26th 1840—the greatest fall of rain on the 27th 1841—the greatest number of days on which rain fell was 11 in 1841.

Middleton Correspondents

Rick Mysteries by our Cambridge Contributor.—Many of the Readers advertised last week having been since added to, we repeat the list of those which may still be had. Any subscribers who will forward to our publisher Post-office stamps equivalent to as many Numbers as are required, shall have them sent:—

1841.—3, 6, 9, 13, 14, 16, 20 17, 18, 21, 22, 23, 24, 25, 27, 28, 29 30, 31, 33, 34

1842.—4, 5, 8, 11, 15, 20, 23, 42, 50 51, 52, 53.

1843.—5, 10 11 12 13 14, 15 16 17, 18, 20, 21, 22, 24, 25 26, 27, 28 29 30, 31, 32 33, 34, 36, 37, 38 40, 41, 43, 45, 48, 49 51

1844.—All the Numbers for the present year; but parties are requested to complete their sets forthwith.

American Blight.—*R. Pye.*—Camphorated naphtha will completely destroy the pest if applied with perseverance.

Books.—*M. N.*—The most useful system of Botany for Gardeners is, beyond all comparison, the Natural. Begin with Lindley's "School Botany," or Francis's "Favourites of the Flower-Garden," noticed by us at p. 30.——*A Visitor.*—Mills on the Cucumber.——*An Amateur.*—Sweet's "Greenhouse and Hothouse Cultivator."——*J. A. F.*—If you will favour Mr Curtis, of Boyle, Middlesex with your address, he will answer your inquiries.——*A. S.*—It is customary.

Boronia pinnata.—*George Matthews.*—Place your plant in an airy situation, and syringe it once a week with nitre dissolved in water, at the rate of 1 oz. to a gallon: if this does not destroy the mildew, dust the plant slightly over with flowers of sulphur.

Calceolarias.—*F. N.*—Standish's Eclipse, and Standished, Harper's Bridesmaid, and Landtaker; Green's Prince Albert, Sulphurea Superba, Miss Antrobus improved, Zebrina, Alba speciosa maxima, Royal Standard, Mary, and Widmer's Prince of Wales.

Cherries.—*Dodman.*—Several of Bottner's Cherries have fruited in this country; one is entirely yellow; another a Black heart, a very abundant bearer; and his October Morello is smaller, but much later than the common Morello. The Black heart, Kentish, and Black Eagle, are sorts likely to succeed in your soil. Others may be tried when you improve it.

Cineraria.—*F. N.*—Beauty of Wortham, Black Knight, Captivation, Red Rover, Regina Victoria, and Henderson's No. 7.

Decayed Leaves.—*W. K.*—Tree leaves from plantations where the ground is full of Dandelion, Ragwort, Chickweed, and other troublesome weeds, will, of course, swarm with their seeds; and although the steam may be now getting hot, such seeds will not be destroyed. You had better add gas water to the heap; this will produce a violent heat, kill the weeds, rot the leaves, and improve their quality as manure.

Falling Leaves.—*Hibernicus.*—A couple of people were to collect the falling leaves, and let them lie in water till entirely decayed, the liquid would be beneficial for watering plants with; more especially if there damp water that the leaves are left in.

Fish Ponds.—*E. W. M.* enquires whether Poplar leaves can affect Fish Ponds injuriously. His keeper complains of the loss he sustains in the stews at this season, and thinks the Poplar leaves which fall in most be the cause of the mischief. Will any learned Ichthyophilus enlighten him?

Fruit Trees.—*Dodman.*—Your trees will not produce well flavoured fruit on cold, wet, clayey soil, whilst they remain planted in the usual way on the natural level. In a similar case, however, great improvement has resulted from the ground being formed into beds raised considerably by soil from large intermediate trenches. The beds may be about 15 feet in breadth, and the width of the trenches 5 feet.

Fuzzes.—*Lancastriensis.*—"J. D." was an anonymous correspondent, and we have no means of communicating with him.

Gamboquia Hookeri.—*A.*—The brown spots on the leaves of your plant are caused by damp. The only way to prevent this is to give your greenhouse plenty of air in sunny days, and a little fire-heat at nights, in cloudy weather.

Gennaria Zebrina.—*A Constant Reader.*—This plant sometimes drops its flowers without any apparent cause, but it would appear that yours requires more heat and more moisture to bring the flowers to perfection. The plants which you received in bloom from your friend had doubtless got a check on being removed.

Gooseberries.—*A Young Beginner.*—The following are some of the best early and late varieties.—Red Champagne (Keen's), Seedling Warrington, Red Warrington, Leigh's Rifleman, Melling's Crown Bob, Red Turkey, Rough Red, Yellow Champagne, Early Sulphur Rumbullion, Glenton Green, Pitmaston Green Gage Massey's Heart of Oak, Woodward's Whitesmith, Taylor's Bright Venus, Early Green Henry, Rob Roy, Knight's Large Red. Currant, is a preferable variety.

Heating.—*Inquirens.*—It is not possible to make the air inside a propagating house as suitable for cuttings when they are first taken off as the inside of a bell glass or hand light. The soil or sand in which cuttings are placed, will not receive as much water from setting the pots on an inch of sawdust, placed on slate over a tank, as they will from being plunged up to the rim in the same situation. Of all materials for this purpose, sawdust is the worst.——*A Disciple.*—Blue clay will not make water tanks tight, except in a very imperfect manner, and if you attempt to heat such tanks, you will, among other evils, find your boiler choked up presently with mud. At p. 394 of this year, you will find a receipt for a cement which it is said will not rot cotton. Your correspondent asks, if anybody in Ireland has adopted the tank mode of heating?

Herbaceous Plants.—*An Old Subscriber.*—The following flower in April and May, viz.—Anemone palmata yellow, height 4 inches; Cheiranthus ochroleucus yellow, 6 inches; Helleborus purpurascens, purple 9 inches; Arabis grandiflora, white 6 inches; Alyssum saxatile, yellow, 6 inches; Iberis sempervirens, white 6 inches; Silene pendula grandiflorum purple, 9 inches; Epimedium grandiflorum light pink, 4 inches; Primula cava, white, 8 inches; Phlox nivalis, white, 3 inches; Primula grandiflora, purple 1 foot.

Hybridising.—*J. H.*—The anthers are the male part of the Fuchsia, and the stigma the female. Fuchsias are not unisexual, except in the instance of Fl. cylindrica.

Insects.—*J. S. A.*—You should have fastened the cork in with a wafer or sealing wax to prevent its crushing the animal, which is a Podura but the species we cannot name. *R.*——*J. L.*—Your Wheat is infested with the Polydesmus complanatus. We must refer you to the *Gardeners' Chronicle*, vol. i. p. 198 and the "Royal Agricultural Journal," vol. v. p. 380, where you will find all that is known concerning its economy, &c. *R.*

Ivy (Hedera Helix Arborescens).—*A Correspondent.*—Stopping at every joint is practised only whilst the plant is young, in order to make it bushy, and when an abundance of stems are thus produced—the flowers being terminal—stopping, of course, must be discontinued for some time previously to the period when it is desirable to have the plant in flower.

Lithography.—*J. Ansell.*—Your flowers are very curious. They are buds trying to bloom, or if you like it better, in a state of change into flowers. In this case the whole structure of the flower is broken up, and the *external scales of the flower are changed into anthers*—an extremely unusual occurrence.

Names of Pears.—*Apis.*—No. 5 St Germain, 6 Chaumontel; 7, 8, Passe Colmar; 9, Beurré de la Motte.——*J. H. Haycroft.*—1 Passe Colmar, 2, Colmar Meurens; 3, Easter Beurré.——*R. A.*—Hollandsbury.——*Mary Ann.*—No. 2 Gilbert Moreau, 4, 7, Bergamot Musqué, 8 Brewing Pear; 5 Beurré Ranee; 9, Alfriston; the other large Apple is the Blenheim Pippin.——*J. P. E.*—9, Hollandsbury; 2, Beauty of Kent, 3, White Russet; 4, Yorkshire Greening, 5, Cat's Head Beauties 6, Sloup Leadington; 8, Holland Pippin, 9, Herefordshire Pearmain; 10, De Neige; 11, Dutchelow's Seedling; 12, King of the Pippins, Mr Rogers's Russet; 15, Court Pendu Plat; 16, Yorkshire Beauty; 18, Stone Pippin; 19, Nelson Codlin, Forelock of Devonshire; 20, Northern Greening; 24 Court of Wick; 27, Marmalade, 28, Old Nonpareil; 29, Drayman's Russet; 31, Pavement Pear; 34, Spanish Bon Chretien; 37 Chaumontel; 38, Dredale's St Germain; 39, Trumpington, 21, 29, 37, are correct.——*E. A. B.*—1, Autumn Pearmain; 2, Knutsford Fillbasket; 4, 11 Blenheim Pippin; 5, Lamb Abbey Pearmain; 6, Norfolk Beaufin 10; London Pippin; 13, Royal Russet, 15, Yellow Ingestrie 17, Nonpareil; 19, Hawthornden; 21, Easter Pippin; 22, Cornish Aromatic 1, Swan's Egg; 3, Gloat Morceau; 9, Beurré de Capiaumont; 4, Maiden Blush; 5, Bourré Rance; 6, Black Worcester; 7, Crassane.——*E. V.*—Your Apple is not the Old Golden Pippin; it is the Reinette Dorée. The other's the Golden Noble.

Names of Plants.—*Elsie.*—A female Yam, and hardly different from *Dioscorea sativa*.——*J. S.*—Some Malvaceous allied to *M. pilosa*.——*Vestal and J. H. H.*—Plants out of flower cannot be named.——*Constantia.*—1, Carlina acaulis; 2, Veronica agrestis; 3, Juncus pentiandrus.——*W. Hardie.*—1, Unknown to us; 2, Epidendrum cochleatum; 3, Oncidium Lanceanum; 4, Epidendrum (?).

Pears for Walls.—*Q. S.*—For a south aspect, Beurré Marie Louise, Jargonelle, Bacon's Incomparable, and Beurré d'Aremberg, the latter for stewing. For east or west aspects, Grand Morceau, Passe Colmar, Winter Nelis, Knight's Monarch, Comparable, Beurré Bosc, Beurré Diel, and Glou Morceau.

Pelargoniums.—*K.*—In shallow pans, in frames, which are kept in small pots during winter. It is much better to shake the greater part of the soil from their roots, than to pot them with the old ball entire.

Primula.—*T. W.*—Your seedling Primula is very pretty, but it possesses no peculiar merit to make it desirable for general cultivation; it is one of those pale-coloured sorts that every summer of seedlings is sure to have.

Rhododendrons.—*W. S.*—If you place your common Rhododendrons, which were only worked last August, on a hotbed in next March, you will be very likely to force them, and particularly if the stocks on which they are worked (which were not well established) be potted. Your best plan will be to place them in a moderately warm greenhouse, and allow them to start gently, for if you do not do this all the forced growth obtained by heat during March will be the ruin of the after health of the plants. Syringing and sprinkling should manure, or excite them to premature growth, as I propose, since you intend finally to plant them in the open air.

Vines.—*A Constant Reader, and A Beginner.*—It is impossible to have good Grapes unless their roots have proper space for strength and air. They are under the same circumstances when they are planted to a great depth. Border where the Vines in pots and yet clayey loam 2 feet deep, and in the room prepare a heap of this stuff must be made use of, and a compost for the outside borders thoroughly mixed with it, and then rubbish with it, so as to loosen it thoroughly, and bring the roots to the very surface. It is necessary to add lime, and not to grow Grapes without it. Your Vines in pots must be kept in the driest place possible during winter, with just enough water to prevent the wood from shrivelling

GUANO (GENUINE PERUVIAN & BOLIVIAN)
ON SALE, BY THE ONLY LEGAL IMPORTERS,
ANTONY GIBBS AND SONS, LONDON;
WM. J. BYERS AND CO., LIVERPOOL;
and by their Agents,
COTESWORTH, POWELL, AND FRYER, LONDON;
BIBBY, BAINES, & CO., LIVERPOOL and BRISTOL.
47, Lime-street, Nov. 23, 1844.

DR. HALLETT'S DRY SOLUBLE FERTILIZER'S are, considering their perfect, the cheapest Manures in use, for they are entirely composed of the Phosphates and other salts of ammonia, and other acknowledged powerful fertilizers. They are fifty times the Public as tried things (see No 23 of the *Gardeners' Chronicle*, &c.) 3 cwt. of either has been found equal to nearly 20 tons of ordinary horse manure. They are applicable to all sorts of field and garden crops. No 1 for heavy clay growth, as Corn, Hops, &c No 2 is for all roots, and a sure preventive of the Fly in Turnips Price of each, 10s per cwt. of the powder.

DR HALLETT'S CONCENTRATED LIQUID FERTILIZER is extensively used by Gardeners for improving the size and flavour of fruits and vegetables, and accelerating their growth, and perfecting the seed of flowers. In quarts at 2s 6d., and in bottles, six times the size, at 10s. Each quart requires 28 gallons of water, to reduce it for use.

Agents for the above London—Mr Bothergill Thames street; Mr. G. Gaiton, the Pottery, Broadwall Blackfriars; Messrs. Warner & Warner, 26, Cornhill; Messrs. M'Mullen, 6, Leadenhall street; Wigsell, Poultry; Pass & Co. PATRIOTIC CLUBS.

Nov 28—Chelsea | Nov 29—Ravel ist
Nov 30—Framlingham | Isle of Thanet

Our readers are doubtless well acquainted with the theory propounded of late years by Professor Liebig, to account for THE PHENOMENA OF ANIMAL NUTRITION. A number of facts occurring, not only in the natural history of our own species, but also in the every-day experience of the stock farmer, which till then had been very imperfectly understood, have been satisfactorily explained by it. The process of fattening, in particular, in dependence on the circumstances in which the animal is placed, and on the sort of food given to it, has thus been illustrated by a consideration of the absolute composition of that food—for a knowledge of which we are indebted to the processes of chemical analysis—and by a consideration of the influence of warmth and comfort on the sources of waste within the animal frame.

Setting aside their mineral ingredients, Professor Liebig arranges the proximate elements of all sorts of food in two classes—the one containing gluten, albumen, casein, legumin, which are in fact different names for the same substances, according to the source whence it is derived, and which are, moreover, all identical with animal fibrine, the basis of muscle or flesh—and the other consisting of sugar, starch, &c., substances containing much carbon but no nitrogen, the element which is characteristic of the first mentioned series. After digestion, it is believed that all gluten, albumen, &c., in the food simply pass from the vegetable structure, where they existed, into that of the animal, without any chemical change taking place on them—that, in fact, so far as this class of substances is concerned, nutrition is not a *chemical* process at all. With reference to the second class of substances, again, it is believed that they are simply fuel for the preservation of animal heat, to be burnt in the lungs, and the circumstances—artificial warmth, &c.—which render but a small quantity of fuel, *requisite* for this purpose, being precisely those which render the combustion in the lungs of only a small quantity of fuel *possible*, that any surplus material, of this class, which under such circumstances may occasionally occur, undergoes in the body a chemical change with combination with certain elements always to be found there, and assumes the form of fat. Excepting the results of some lately published experiments in France, the hitherto recorded facts bearing on this subject, which have been examined, prove in this manner a very satisfactory explanation to be indeed applicable. Playfair showed, in his able lectures before the Highland Agricultural Society

The second part of Liebig's theory—that which relates to the formation of fat—has been objected to, we believe, from the first by Mr. Dumas and other French chemists; and the results of experiments we have just alluded to, which are published in the last number of the Annales de Chimie et de Physique, are also so much opposed to it, and so important in many respects, that we hasten to place them before our readers.

It is asserted by the French chemists that nutrition not only with reference to the formation of flesh, but in respect to the fat also, consists simply in the shifting to their positions in the animal frame of elements already perfectly formed in the vegetable—that is the fibrine of the animal exists as gluten or legumen, &c. in the vegetable, as animal fat is obtained from the fatty matter occurring in most vegetable substances. They altogether deny the formation of fat out of the surplus sugar, starch, &c., which we have already referred to as fuel for the lungs; and their denial is founded on facts similar to the following:—

With the view of determining between the rival theories, M Boussingault subjected two milch cows to three different descriptions of diet in as many successive fortnights, or in periods of about that duration. They weighed at the commencement of the first experiment, 1262 lbs. and 1280 lbs respectively They were then put on a diet of Mangold Wurzel alone for 17 days, during which they ate 2321 lbs and 2477 lbs. of this root, and yielded 26 and 27 gallons of milk respectively The following is the composition of the milk —

	1st Cow	2d Cow
Cheese	3 67	3 81
Sugar of milk	5 49	5 74
Butter	4 86	3 44
Alkaline chlorides	0 43	0 46
Phosphates	0 28	0 26
Water	87 73	86 23
	100	100

The excrements of these cows during this period weighed 574 lbs, containing 91 lbs. of dry matter, and 3 3 lbs. of fatty matter The cows, towards the end of the experiment, daily lost weight, and became much emaciated, they weighed at the end of 17 days 1175 lbs and 1188 lbs respectively Mangold Wurzel, M Boussingault had by previous analysis found to contain $\frac{1}{1000}$ part of fat, and 0021 of nitrogen, 00046 of phosphoric acid The following, then is a tabulated statement of this experiment.—

	lbs	Fatty matter lbs	Cheese, albumen &c lbs
Two cows have given—milk	460	17 20	17 2
" " dry excrement	91	3 3	undetermined
Fat matter in the products		0 93	
Mangold Wurzel consumed	4798	4 8	
Fat unaccounted for		10 49	

Weight of cows at commencement 2512 lbs
" " termination 2301 "
Loss of weight during the period 179 lbs

Supposing, as we are bound to believe, that the quantity of the starch, sugar, and other carbonaceous elements in the roots, were present in quantity abundantly sufficient to supply the respiratory organs with fuel, then the fair inference from this experiment is that the cows, not finding in their food a sufficiency of fat to supply the butter of their milk, &c, and being *possessed of no power to convert starch, sugar, &c., into fat*, were forced to draw upon that already deposited in their own tissues—hence their loss of weight The animals, M Boussingault informs us, were so emaciated that he was forced to put them for three or four days on their original food, hay, before he could venture to proceed further with the experiment

At length he placed them and kept them for fourteen days upon a diet of aftermath hay, and of this experiment we shall at once tabulate the results, without making any preliminary statement The aftermath was found, by analysis, to contain 3 5 per cent. of fatty matter, 0012 of nitrogen, and .0031 of phosphoric acid The quality of the milk from the two cows during this experiment was as follows:—

	1st Cow	2d Cow
Cheese	3 65	3 65
Sugar of milk	5 45	5 94
Butter	5.92	4 30
Alkaline chlorides	0 45	0.53
Phosphates	0 27	0 29
Water	86 27	87.30
	100	100

The following are the results of the fortnight's experiment on the hay diet:—

	lbs.	Fatty Matter lbs	Cheese, &c lbs
The two Cows gave—milk	261	10 34	11 66
" " dry excrements	107	1 12	
Fat matter in the products		11 46	
Potatoes consumed	2367	0 73	
Fat matter unaccounted for		8 73	

Weight of Cows at commencement 2350 lbs
" " " termination 2288 "
Loss of weight during the period 72 lbs.

Here, again, where the fatty matter supplied in the food exceeds that required for the milk, &c., it is deposited in the tissues of the animal, and we accordingly find that the cows have almost regained their original weight.

The following is a tabulated account of the third experiment, which lasted 14 days, during which the cows were fed only on Potatoes.

From three analyses of the Potato, M. Boussingault concluded that it contained 002 of fatty matter, 0037 of nitrogen, and 00109 of phosphoric acid.

The quality of the milk during this period was as follows:—

	1st Cow	2d Cow.
Cheese	4 87	5 00
Sugar of milk	3 09	4 00
Butter	3 97	4 62
Alkaline chlorides	0 55	0 55
Phosphates	0 27	0 27
Water	87 75	85 57
	100	100

	lbs.	Fatty Matter lbs	Cheese, &c, lbs
The two Cows gave—milk	261	10 34	11 66
" " dry excrements	107.	1 12	
Fat matter in the products		11 46	
Potatoes consumed	2367	0 73	
Fat matter unaccounted for		8 73	

Weight of Cows at commencement 2350 lbs
" " " termination 2288 "
Loss of weight during the period 72 lbs.

Here, as in the first experiment, we have a loss of weight which can only be accounted for on the principle there stated, that the cows were forced by lack of fat in the food, to draw upon the stores in their own tissues, at the expense of their weight. These results are apparently opposed to that part of Professor Liebig's theory, which endows animals with the ability to form their fat out of any excess of the carbonaceous elements of their food

As M Boussingault says:—"These experiments evidently show that Mangold Wurzel, as Potatoes given alone are insufficient for the proper nourishment of milch cows even though they be given abundantly, one might almost say *ad libitum*, since very often the cows left portion in their mangers

"A diet may be insufficient for several reasons:—1, If the food does not contain such a quantity of nitrogenised matter as may serve to replace the matters equally nitrogenised, which are constantly wasting from the body; 2, if it does not contain the carbon necessary to replace that which is burnt in the act of respiration, or carried off in the secretions; 3 if it be not sufficiently charged with the salts, particularly the phosphates, necessary, moreover to the economy these same matters which are continually expelled, and 4, it appears from our experiments that food will be insufficient, if it be not rich enough in fatty matters, to supply those which are carried off in the milk and other secretions."

Referring to his experiments, he adds, "The facts I have collated will doubtless receive many explanations, but that which appears to be the most natural, consists in admitting that the food of herbivorous animals ought always to contain a certain quantity of substances analogous to fat, destined to assist in the production of the fatty tissues, and bile which contains fat in considerable quantities If notwithstanding the insufficiency of their diet in this respect, cows should continue to give the same milk, &c., as they yielded under a complete alimentary *régime*, it is because they elaborate these secretions at the expense of their own fat. Possibly, for a limited time, cows may continue, under such circumstances, to give the same number of gallons of milk, the quantity will not diminish sufficiently, but each day also, as I have proved, they will lose 4 or 5 lbs of their own weight; and if we persist in administering an *incomplete* diet, however *abundantly* it may be supplied, they will ultimately become so emaciated as to endanger life"

ON THE FARMER'S DUNGHILL.

I AM not about to offer a solution of the most difficult problem in agriculture, but only to state a fact in proof of the great importance of having a practical answer to the practical question—How must I make a dunghill? I have attempted to estimate the quantity of carbonate of ammonia which escapes into the air during the fermentative process of converting farm yard manure into a suitable compost for land. The value of the manure lies chiefly in the nitrogenous substances which are retained in it, and it is deteriorated in proportion to their escape. The quantity lost may be estimated by the following experiment:—If a slip of glass, about 3 inches by 1, be moistened with 2 or 3 drops of hydrochloric acid (spirits of salt or muriatic acid) spread uniformly over 2 inches of its surface, and then be held in the vapour arising out of a dunghill, its acid surface being downward, it will be found that in the minute a portion of carbonate of ammonia, amounting to $\frac{1}{1000}$ of a grain, has been fixed by the acid, and converted into a hydrochlorate of ammonia. Upon evaporation over the flame of a candle, the feathery crystals of the salt will be immediately recognised under the microscope.

Now, every 2 inches of the surface of the dunghill offering an escape to an equal quantity of ammonia, it follows that every square yard of surface loses every minute at least 8-5ths of a grain of this carbonate, and every day about 2 ounces. If the hot fermentative process be continued for a month, each square yard will, at

[illegible] the use of this valuable [illegible] will not be taken too [illegible] it in [illegible] the dunghill, during the [illegible] position, to [illegible] evolve at once [illegible] square [illegible] that upon the [illegible] there will be a loss of [illegible] commercially, a [illegible] of what would suffice [illegible] with every pound [illegible] evaporated, a loss of 60 lbs. of [illegible] *Agricultural Chemistry*, page [illegible] the accuracy of the Professor's [illegible] account between Corn and manure, [illegible] and I will give any one all the Wheat I grow if I will [illegible] grow all that I lose. At all events, the [illegible] of getting our volatile friend into "a fix" is most [illegible], and for this *purpose* we may use with advantage both gypsum and sulphuric acid. On making the dunghill in the *first* instance, and when subsequently turning it over to *accelerate* fermentation and decomposition, it will be advisable to strew a thin layer of gypsum after every rise of 2 feet of manure. And ultimately we may pour on the top as many pounds of sulphuric acid, diluted each with a bucket of water, as there are single horse-loads in the dunghill. I can state, as the result of experiment, that this application of dilute acid [illegible] effectually checks the evolution of vapour and the escape of ammonia, and consequently, at a very small cost, it improves the agricultural value of the manure, and therefore tends to secure what Liebig holds out as the reward of good farming—"the best possible crop every year."—*J. B. Neade, Stone, Aylesbury.*

THE RELATIVE POSITION OF AGRICULTURE.

Everything connected with Agriculture seems anomalous. Agriculture and Manufactures, Trade and Commerce, are really bosom friends. Still they appear to be sworn enemies—a gulf of non-communication yawns between them; they are like a chain in two parts, wanting a connecting link to render it available. The connecting-link in the disunited chain must be "Capitalised Companies for the Improvement of Agriculture."

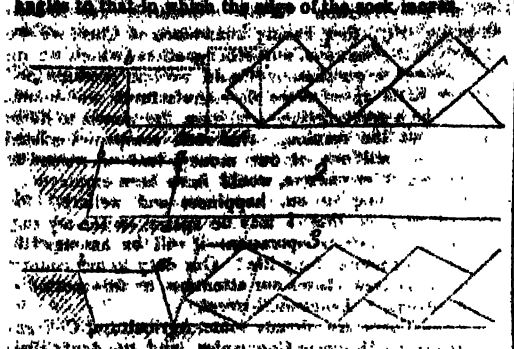
Agriculture and manufactures are not antagonistic interests, but the reverse. They are as essential to each other as the limbs to the body—[illegible] of the one must be sympathised in the other. Agricultural production is the [illegible] of [illegible]. [illegible] is food which [illegible] incomprehensibly [illegible] to us, and [illegible] for a day, is the misery of [illegible] The [illegible] of [illegible] bringing in Returns [illegible] The precious metals or credit [illegible] the [illegible] between them. It is a well-established [illegible] that there is in trade, manufactures, and commerce, a superabundance of capital, whilst in agriculture it is sadly deficient. Ask an improving landlord or [illegible], why their various improvements are so [illegible] and temporarily checked—they will say, not [illegible] for [illegible] sufficient command of money to [illegible] talented and spirited agriculturists [illegible] and restricted by the want of that capital [illegible] abounds as scarcely to [illegible] consequence forced into rash [illegible] of interest to loans to foreign nations, with whom we may be to-morrow at war, and who now injure us in trade, &c.

In agriculture there are few or no bills of exchange, or other means by which an honest and industrious man may trade on the capital of his wealthier neighbour. In trade, commerce, or manufactures, the abundance of capital permits all the advantages of an extended credit. In agriculture but few such facilities exist. It is the want of capital that causes so much fat [illegible] but of agriculture, labour. A good farmer will readily admit, that every item of labour pays a profit, and that the more labour he employs the greater is his advantage. But [illegible] Where is the money to [illegible] Who's to find it? Tis [illegible] long mouths, at [illegible] to be returned to him.

[illegible] very best of capital when employed, but we [illegible] it with money payments, nor [illegible] without money payments, by means of [illegible] and [illegible] the industrious [illegible] to [illegible] but inconsistently enough, pay [illegible] pence of [illegible] to restrict [illegible] on his non-employment [illegible] I mention these matters as strong [illegible] necessity of applying the [illegible] to the improvement of agriculture. A man [illegible] of ground, has a stake in the [illegible] and poverty all [illegible] employment and comfort [illegible]

Self-interest [illegible] question, but the [illegible] general welfare [illegible] to those counties—Lincolnshire [illegible] and Essex a pig or a cow, [illegible] being [illegible] As a natural consequence, [illegible] education; and their [illegible] of those without either cow, pig or land; [illegible] half-a-crown or seven or eight shillings per week. The comparative criminal records of these districts would be instructive. The condition of the cottager is the true [illegible] a true index to the character and position of his employer. Want of employment, under any circumstances, is injurious to the community at large. Too much thinking, and too little muscular action, is prejudicial to the working classes, and positively dangerous. Non-employed individuals [illegible] but, as they produce no food, they [illegible] of the industrious—this is an [illegible] one, felt but not seen.

Let us inquire why [illegible] to every foreign loan or [illegible] scheme—why [illegible] give strength to foreign [illegible] and to weaken our own. We [illegible] in [illegible] and [illegible] for every object [illegible] in [illegible] to [illegible] the [illegible] to be because we do not [illegible] in our limited [illegible] to [illegible] [illegible] to improve the [illegible] [illegible] [illegible] [illegible] It is because we have no [illegible] and [illegible] channel for the profitable investment of surplus capital in agriculture [illegible]



Ignorance and want of combination are at the root of the evil. Everything in this way is left to individual enterprise. As well might a single shareholder attempt constructing his portion of a railway, with all its complicated accompaniments! Imagine him attempting such an object, himself without experience, and unaided by all the various aggregation of talent necessary for the details of such an operation. The idea is absurd; and yet the scarcely less complicated operation of landed improvement is, up to this hour, left in the position I have described.

Ask a capitalist, why he does not invest his money in land or agriculture? He will look sternly grave, and quote a hundred instances where individuals have ruined themselves by such a course. So now he rushes into some foreign loan or project, to the great injury of his own countrymen, fearful of the "law's delay" in conveyance with all its multifarious objections, *pro* and *con*, most likely alarmed by the rumoured fate of some friend who, having at last got his estate, knows nothing about the management of it, and after struggling with incompetent tenants or designing ones—new leases, valuations, tormenting applications for repairs to the old dilapidated buildings, appeals for returns of rent, and a hundred other vexations, finds his rental reduced to 2½ per cent or less, sells at a loss, and retires from the contest in despair. His example is quoted, and his mishap magnified to a hundred other capitalists, who ever after, from father to son, shun the dangers of meddling with so disastrous an affair as landed investment.

As to agricultural improvements, why if a man has the courage to attempt it, he will at the outset encounter a host of doubts, prejudices, and obstructions—a hundred conflicting opinions as to the width, depth, distance, and materials of his drains will present themselves. Should he by good fortune settle this matter rightly, he is astounded with multifarious suggestions on subsoiling and courses of cropping, quantities and distances of seed, and state of crops for harvesting. As to artificial manures, a very host of nitrates and sulphates beset him in front and rear, with soot, salt, and guanos on every side. He turns pale at the perspective of lime and chalk. Undecided and bewildered by their contending claims, he is coolly told that a perfect knowledge of agricultural chemistry, geology, entomology, and botany, can alone enable him to decide correctly. Having pondered upon the respective merits of short horns, long horns, and no horns; Downs, Leicesters, Cheviots, Kents, and Cotswolders; and whether corn, cake, Carrots, or Colewoits, are most fattening—he hurries away to inspect a thousand complicated implements of agriculture, which it would require a life of mechanical education and skill effectually to appreciate and discriminate. In despair he gives up the contest, loses his money or dies, leaving no authorised version of the knowledge he has acquired, but bequeathing to the venturous few the same course of toil, trouble, doubt, and disappointment; but had he succeeded, his motives would be misrepresented, his facts disbelieved, and his character blackened by those who consider that agricultural ignorance is bliss, and that improvement opens the eyes of the landlord, to the injury of the tenant. Now all this might be easily obviated and prevented by a well conducted company, having practical directors, with proper engineers and officers. Do away with the law of mortmain as regards such companies. Let them purchase waste or poor lands—drain, clear, trench, crop, and let them. Let there be five companies, and their shares quoted at the stock exchange the same as railway companies. Their success would depend upon their abilities and results; and a man disposed to invest his money in agricultural improvement could, without any personal trouble, buy or sell his shares, or breathe them, without more [illegible] of gain them attends any other investment.

The importance of such [illegible] to the [illegible] community; all other [illegible] however [illegible] I consider secondary and [illegible] to our daily bread. [illegible] Let our city [illegible] and [illegible] agricultural [illegible] consume [illegible] and [illegible] Let them consider their [illegible] as they really are. [illegible] and [illegible] daily papers lists of Land Improvement Companies for every county in England, Wales, and Ireland, quoted on the Stock Exchange! How pleasant to read and compare the [illegible] and success of a hundred such companies, [illegible] of [illegible] [illegible] [illegible] [illegible]

right angles. On looking at fig. 1 and 2, representing sections of ploughed land, it will be seen, upon what the greatest surface will be exposed when the work is most regular. The smallest proportion of which a sod can be cut and turned in a right manner, we need, therefore, not at present enquire into; in order to insure this, the plane in which the coulter of the plough moves must, of course, be at right angles to that in which the edge of the sock moves.

I may state, moreover, without quoting the mathematical proof of it, that the greatest surface will be exposed when the turf lies at an angle of 45°, as in fig. 1 above, and that the turf will lie in this position only when its depth is to its breadth as about 7 to 10.—*M. S.*

SKETCHES OF EAST LOTHIAN HUSBANDRY.

Culture of Potatoes.—The quantity of this valuable esculent grown in East Lothian is not very considerable, their culture being chiefly confined to the vicinity of the towns and villages where they are planted by a few farmers for sale, and by tradesmen and labourers. Potatoes are not cultivated to any extent as food for cattle; in the majority of instances they are planted merely to supply the farmer's own house; each hind also receives as part of his annual wages Potato-land equal to from 1200 to 1500 yards along a drill, or 5 bulls (2½ qrs.) of Potatoes in lieu of the ground.

Potatoes are generally taken after a crop of Oats, but they are also occasionally planted upon land newly broken up from *leas*, although this is an obvious violation of the principles of alternate cropping. The preparation of the land for Potatoes being in much respects similar to that requisite for Turnips, described in my last Paper, it is unnecessary to occupy much space in noticing the preparatory culture of this crop. The East Lothian farmers do not pretend to extraordinary skill in growing Potatoes, but they are all perfectly aware that the more effectually the soil is reduced and deprived of root-weeds, and the nearer it is brought to a state deemed sufficiently pulverised for Turnips, so much the more certain will be the prospect of an abundant crop. As in the case of preparing the land for Turnips, repeated ploughings, harrowings, rolling, and grubbings, are given to that intended for Potatoes; but the nature of the soil, and its condition in respect of weeds, form the only guide for determining how frequently these operations are to be performed. It is of great importance, and particularly so in droughty seasons, to get the soil as finely pulverised before planting the sets as possible, as it is well known that cloddy drills, however well rolled after being formed, considerably aggravate the evil effects of drought, besides diminishing the beneficial influence of moisture.

The usual period of planting is from the middle of April to the middle of May. When the ground is sufficiently prepared, and the proper time arrived, the drills are formed, precisely in the same manner as in the case of Beans and Turnips, but with this difference, that for Potatoes the drills are made about 3 inches farther asunder than for either of these crops. The manure chiefly employed is dung or compost, it is invariably carted out in the field during the previous winter, or early in the month, and in general ever to commence its fermentation, a week or so before being applied to the land. While the drills are being formed by the plough, the manure is carted from the heaps and equally distributed along the hollows of the drills. The sets are then placed at the proper distance—from 8 to 12 inches—apart upon the manure, and are immediately covered by the drills being split with a light coulter.

[illegible] with a view of destroying the seeds of weeds, and this practice is sometimes followed [illegible] but in most cases, where the soil is in a tolerably [illegible] the cutting of [illegible] they are planted and the [illegible] with [illegible] is also extensively employed [illegible] with the best [illegible] after being [illegible] of Grass-seed [illegible] appear [illegible] being performed [illegible] above the [illegible] have [illegible] Altogether, [illegible] hand-[illegible] Potatoes [illegible] the [illegible] by the [illegible] Potatoes [illegible] the [illegible] within [illegible] [illegible] [illegible]

good crop in their neighbourhood. The present sample is an average one, and was only kept by the bailiff of Mr. Shoreham's for his own guidance, and not for purposes of exhibition. There is a quantity of Wheat lately arrived from the colony, and more is expected. I will procure a sample, and forward a small quantity at Chiswick.—*Edward Sherwood.* [The ears are of average length, and exceedingly well filled; the grain—it is white Wheat—is of good sample.]

Sea Buckthorn.—The "Old Subscriber" is informed that the botanical name for Sea Buckthorn, or common Sallow Thorn, is Hippophaë Rhamnoides; he will find it mentioned in Loudon's Encyclopædia of Botany; or, Systematic Arrangement of British Plants, with some account of the uses, &c. &c. The soil may not be as it ought to be, if the plant does not take an interest in such matters, in the opinion of "A. D. B." will add that it is found on the sea-shore, in sand; at Lindisy Coast, Lincolnshire; Hunstanton, Deal, and Folkstone, Kent; Isle of Sheppy, Kent; and Sheringham Cliffs, Norfolk; between Whitby and Scarb, Yorkshire. It is very easily propagated by suckers or layers, or even by seeds. Rabbits do not disturb it; it grows to 8 or 12 feet high, and forms a handsome shrub, or even shelter to other shrubs that will grow in sandy soil by the sea-side. There have been several editions of "Withering's Botany;"—the last should be asked for.—*M. D. P.*

Guano.—I have had for many months guano and common salt in separate bags, standing a little distance from each other in my barn. The other day I had occasion to use some salt, and on breaking the lumps they smelled almost as strongly of the guano as the guano itself. How is this to be accounted for? The salt has evidently drawn to itself, and imbibed and retained the volatile matter of the guano; and this, I suppose, must render the salt more beneficial for agricultural purposes. —*Ultimator.*

A Few Hints.—1st. One of your correspondents has said that flukes in rotten sheep are only found in the liver, but I have seen them come from the uterus, with the lamb or yeaning. 2d. *Draining.*—Our country is capable of being improved more by drainage than by any other means; manuring is but a secondary article, compared with draining, and I calculate that there is in our part of the country enough draining required as would employ about the agricultural labourers for half-a-dozen years at least; and draining land, excepting the carriage of the material, is a landlord's business, and not a tenant's. It appears possible to double the value of some districts by draining, about which probably those neglected, undrained districts, amount to half the land in this kingdom. Another important part of the farmer's business, intimately connected with draining, is deep cultivation of the soil, as compared with the poor shallow cultivation now generally practised. Many farmers—cultivators of the soil—dare not plough up the least quantity of clay, or even marl; they have been taught that it is injurious, by their ignorant forefathers, and idle team-men are interested thus to plough shallow, to save their horses the harder labour. But I maintain that deep cultivation is what we want on all good land; and deeper cultivation, with good drainage, on all inferior clay-land. 3d. Mr. Morton, in his remarks "On the Culture of the Land for Wheat," (see p. 74), has hit the mark in every point; his remarks on this subject are exactly parallel with my own experience. I see in the *Gazette*, for March 2, 1844, Mr. Morton is comparing notes with Professor Low upon the farmer's invested capital; now, as the former of these gentlemen makes his estimate at 12*l.* per acre of the land occupied, and the latter gentleman's estimate is 6*l.* per acre occupied, I think if a third came in between, at 9*l.* or 10*l.* per acre occupied, he would be nearer the truth than either. But, after all, it may be set down as a well known fact, that too many of us farmers are sadly short of capital; and how and where shall we have it? is a very puzzling question. 4th. *Lime.* —The price here is about 10*s.* or 12*s.* per ton, and, at some of the cheapest works or lime-pits, 8*s.* It is common with us to use 3 or 4 tons per acre in lining of fallows, more in late years; and the best way to use it is to get it well mixed with the soil in the shortest time possible—in a fine dry state, both in the land and the lime.—*A Leicestershire Farmer.*

Hybridising.—As Horticulture and Agriculture are united in the *Chronicle*, I know of no better place to bring forward the subject of hybridising or crossing, as I conceive this is far better understood by the horticulturist than by those engaged in agriculture. I believe there are limits to the productive powers of the earth, but there is no limit to what may be done with the vegetables upon it, so as to assimilate the powers of the soil, more as it were to the use of man. Nearly all the varieties of Wheat, Barley, Oats, &c., are, I believe, accidental varieties. The real staple food for man is left, as it were, to chance, while luxury and elegance can produce almost any tint of colour, or description of taste they want. The greatest pains are taken by the gardener and florist to produce artificially new varieties of vegetables and flowers, and experience proves that this may be done to a great extent, and that species may be moulded almost to the will of the practised hybridiser. If, for instance, we had a variety of Wheat that would ripen two or three weeks earlier in the south of England than those we now possess, we might have an excellent crop of Turnips on the dry lands after it, and our stiff soils succeeded with the Cabbage tribe. Again, if a variety of Wheat could be found to grow and ripen at a higher elevation than any we now possess, it would take, in many places, the place of Oats, and the people in the north might have their Wheaten loaf, instead of Oatcakes and "Bannocks of Barley meal." I trust, therefore, experienced hybridisers, whether horticulturists or agriculturists, will join in this good work, which I think is rather too much neglected by our agricultural Societies, and the result will be to render service and duration to our country's happiness, by meeting the wants of our commerce and population. These remarks were suggested to my mind by hearing a landowner, at a meeting of many intelligent farmers, remark that the powers of the earth was limited like our own, and therefore it was of no importance greater things of it than we had already seen, and what he wanted to know was, how to make [illegible] like ridiculed theorists and German philosophers, unworthy of any confidence; and in all things now carried on.—*T. A. F.*

ROYAL AGRICULTURAL SOCIETY OF ENGLAND.

A Weekly Council was held at the Society's House, in Hanover-square, on Wednesday, the 6th of November. Present—[illegible], Esq., in the chair; F. Buller, Esq., [illegible], Esq.; H. Gibbs, Esq.; H. T. Baskerfield Green, Esq.; W. Fisher Hobbs, Esq.; Prof. Sewell; W. Shew, Esq.; J. Villiers Shelley, Esq.; and J. Towers, Esq.

The following new Members were elected:—
Turnston, John, Market-Weston Hall, Bealing, Norfolk
Morgan, William, Brampton Park, Huntingdon
Butler, Captain, Bowling Green, Faringdon, Berks
Hems, John, Seaa-Regard, Jersey
Drury, John George, St. George's-street, Canterbury
Perceval, Hon. and Rev. Charles George, Calverton, Stony-Stratford
Davy, Robert, Ringwood, Hants
Robinson, George, Wolverhampton
Humphreys, John, Evan Hall, Oswestry, Salop
Manning, C. I., Cranford Bridge, Middlesex
Hann, Lockington St. Lawrence, 60, King William-st., City
Price, Walter R., the Rise, Kentchurch, Herefordshire
Garnier, R. N., Drayton Lodge, Norwich
Wingfield, John, Onslow, Salop
Hill, Clement Delves, Sandford Hall, Salop
Harper, George, Belvidere, Whitchurch, Salop
Bick, Michael, Park Hall, Bromsgrove, Worcestershire
Swan, William Robert, Wallsend, Newcastle on Tyne
Bate, Robert, the Square, Bridgewater
Paddon, Joseph, Tarcham, Hants
Hannay, Rev. James, Ashley, Stockbridge, Hants
Wynne, John Lloyd, Jun., Cord Coch, Abergeley, Denbighsh.
Brentnall, Benjamin Tildon, Hemel Hempsted, Herts.

The names of 18 Candidates for election at the next Meeting were then read.

LECTURES.—Communications were received from the Duke of Richmond and Mr. Pusey, M.P., announcing the progress of the arrangements for Lectures to be delivered before the members at their ensuing Christmas meeting in the second week of December, when the rooms of the Society would be thrown open in the evening as formerly for their accommodation, and the General Meeting held as usual on the Saturday of the same week.

BELGIAN CARROTS AND WHEAT.—Mr. Mechi of Leadenhall-street, favoured the Council with samples of the Belgian Carrot grown on his property in Essex, accompanied with the following communication in reference to their cultivation and that of the Wheat, of which he had sent specimens for their inspection on a former occasion:—

"4 Leadenhall street, London, Nov. 16, 1844

"I send a few Carrots of my Tiptree growth. They are the produce of a black sandy field (9 acres) forked 12 inches under the plough, and dressed with dried night soil (which, however, I consider much inferior to guano, so far as I have compared them). They were several times hoed with a deep Bean-hoe. I consider the removal of their lateral fibres obliges the tap-root to go down in search of moisture and food the same remark applies to Swedes. If the season been an ordinary one, I should have had an enormous crop of Carrots, but they struggled hard with fourteen weeks' drought, and only then came to one half or three quarters of a crop. We filled up the blanks with Swedes. Still they will afford useful food. Forty acres of my Wheat (specimens of which I sent you) averaged over 4 quarters per acre, weighing 64 to 66 lbs per bushel; (one field produced 5 quarters 1 bushel). The two fields of March-sown Wheat failed, owing to the drought (so many ears being unripe) producing only 2 quarters per acre of middling quality. (Signed) "J. J. MECHI"

The Council ordered their thanks to be returned to Mr. Mechi for the favour of this inspection and communication; and, on the motion of Mr. SHELLEY, it was resolved, that inquiry should be made of Mr. Mechi, whether the four Belgian Carrots he had sent to the Council were fair specimens of the average crop of the nine acre field referred to in his communication; and also the amount of land and seed Wheat, and of how much land grown.

SOCKET DRAIN-PIPES.—Mr. Henry Dixon, of Witham, in Essex, favoured the Society with specimens of the socket drain-pipes made by him, for the use of his own land; and which, he informed the Council, were particularly applicable to [illegible] soils; and, from their construction, could not fail to be safe. He had found that it was not necessary to make [illegible] and supposed, to have the pipes made [illegible] their sides. The pipes in question might be made of any length, the most convenient ones having been found by Mr. Dixon to be from 15 to 18 inches, and the cost of the socketing, as effected by the Ford's Patent Machine, which he employed, from 2*s.* 6*d.* to 3*s.* 6*d.* per thousand. Mr. Dixon enclosed with the pipes a detailed evidence of the facility with which the roots of trees will occupy drains, if carelessly placed: it consisted of a cylindric mass of fibres from the roots of a Willow-tree, growing about 5 or 6 feet from a drain, which had been put down only 12 months; the pipe from which the mass collection was taken, was a 4-inch socketed one.

Thanks having been ordered to Mr. Dixon for the favour of these specimens and the communication which accompanied them, Mr. Frances Horne fully corroborated the statement then transmitted in times by Mr. Dixon, whom he well knew as a landowner to a considerable extent in his own neighbourhood, and as a disinterested promoter of agricultural improvement. An interesting discussion then ensued, in which Mr. Blount, Mr. SHAWLEY, and Mr. DEAN favoured the Council with the results of their own experience in reference to the accumulation of large masses of water, suddenly formed under peculiar local circumstances of surface in the case of unusual rains, and also in that of springs issuing in considerable volumes from the sides of hills.

Mr. Shaw presented copies of his Translation of Tiner's Rational Principles of Agriculture, and the Farmers' Almanack for the ensuing year; and Professor Low, of Edinburgh, his valuable Lectures on Property and the Economy of Estates. The following presents and communications have also been received:—

The Health of Towns' Commission: Seventh Report of their First Report.
Mr. R. N. Bacon: Prize Report on the Agriculture of Norfolk.
Mr. H. Stephens: Book of the Farm. Parts 20 and 21.
Professor Buckland: Address to the Hampshire Southampton and Arundel Fine Art Committee.
Mr. Dolland: Description of an Instrument invented by him, for the self-registering of atmospheric changes for any period, as indicated by the Barometer, Thermometer, Hygrometer, Mountain-barometer, Rain-gauge, Wind-gauge and Illuminator, and transferred mechanically, every half-hour, to the self-recording cylinder of the Electrotype.
Mr. Munn: Description of his Bar-and-Frame Bee-hive, invented by him; and abstract of Wildman's Guide to the Management of Bees.
Geological Society: Proceedings, Vol. IV., No. 96.
Statistical Society: Journal for September, 1844.
Royal Asiatic Society's Journal: No. XV., Part I.
Agricultural and Commercial Society of Guiana: Laws and Regulations.
Royal Society of Lille: Memoirs and Programme of Prizes.
Royal Society of Lyons: Annals of Proceedings.
Highland Society: Quarterly Journal for October.
Farmer's Magazine for October and November.
Veterinarian, for September, October, and November.
Western Agriculturist, No. II.
Jamaica Agricultural Society: Proceedings.
Canadian Agricultural Journal, Nos. VIII. and X.
American Agriculturist, No X.
Albany Cultivator, No. IX.
Dr. Whitlaw: New York Farmer & Mechanic, No. II.
Mr. M'Nab: North British Cultivator.
Mr. B. Love: Chapter on Working People.
Messrs. Rouke and Varty: Mr. Newnham's Pamphlet.
Mr. Skilling: Farmer's Ready Reckoner.
Mr. Saunders: Paul Pry's Letters to his Countrymen (on improving the condition of the Irish Cottager).
Professor Tilley: Inaugural Lecture on Chemistry in Queen's College, Birmingham.
Mr. Westwood Baker: Prizes of Rutland Ploughing Meeting.
Mr. Lilley: Agricultural Tour in Ireland.
Sir John Tylden: on the Conversion of old Hop-bines into Manure.
Messrs. Herring and Co.: Analyses of Guano.
Mr. Morant on the Quality of Common Salt, as a Manure.
Mr. Evans and Mr. Gee: on the Re-publication in Welsh of the Cottage-Tracts on Gardening and Cottage Economy, in the Society's Journal.
Mr. Babington: on the Botanical Designation of Italian Rye-grass.
Mr. Frere and Mr. Testy: on the Mustard-plant.
Rev. Jos. Nodder: on the Distribution of the Society's Journal among Farmers' Clubs.
Mr. Saul: on an Improved Turnip and Potato Machine.
Mr. Bowden: Sample of Mac Kibbin's Improved Roofing Felt.
Mr. Sheppard: on Guano and Gypsum.
Mr. Rea: on Dutch Butter.
Mr. Towers: on Results of Dibbling.
Mr. Wills: on Allotments.
Mr. Waldron: on Drainage of Land.
Mr. Stevenson: on bruising Oats; and on the Subterranean Telegraph.
Mr. White: on Unemployed Labour, and Spade Husbandry.

The Council then adjourned for a fortnight, to the 4th of December.

AGRICULTURAL IMPROVEMENT SOCIETY OF IRELAND.

AT a late weekly Meeting of the Council a communication was read from the Trustees of the Agricultural Fund of the Irish Reproductive Loan Fund, London, stating that they had agreed to place the sum of 2000*l.* in the hands of the Council, to be annually applied to the purposes of Agricultural Education, either in the provinces of Munster or Connaught. The Secretary stated that the premiums, to the amount of 123*l.* together with 67*l.* in medals, which had been awarded at the late Cattle Show in Dublin, had been paid off, and vouchers received for the same. From 60 to the amount of 40*l.* and upwards still remain unpaid, subject to proof of qualification by the claimants. The whole expenses of the Cattle Show had been also discharged, and a full statement of proceedings would be laid before the Society at the next half-yearly meeting, which was fixed to take place on Friday, the 29th of November, to receive the Report of the Council. The premium sheet for the next

Annual Cattle Show, to be held at Ballinasloe, for the year 1845, was also referred to a sub-committee, to peruse and revise the same, previous to having it submitted to the general meeting for approval. The Secretary also stated that the 2d edition of the Society's Transactions and Report for 1843, together with the maps and diagrams, could be had by members on application, on forwarding tenpence in post-office stamps to cover the amount of postage. It was most desirable that this work, which contained so much useful and valuable information on thorough-draining and reclaiming waste land, &c., should be circulated as extensively as possible, and arrangements had been made for the purpose with the Society's publishers, Messrs. Curry, of Dublin; Longman, of London; and Fraser, of Edinburgh—to distribute them to members at moderate and cheapest terms, where they are not subscribers on application. It also appeared, on reference to the Society's accounts, that there was a great accession of new members during the present year, no fewer than 450 additional subscribers having joined the Society at and previous to the late Cattle Show, several hundreds of whom had joined in order to qualify their local Societies for the premiums they offer. There were, however, considerable arrears of subscriptions still outstanding, and the Secretary was directed forthwith to remind those parties, as well as those subscribers to the local Societies at the Castle Show, to pay up their arrears, that the next Show a full statement of the accounts should be laid before the Society at the next General Meeting.

Reviews.

The Report of the Agriculture of Norfolk, to which the Prize was awarded by the Royal Agricultural Society of England. By Richard Noverre Bacon. Ridgways London.

Next to the possession of accuracy and completeness, we may safely assert that the value of a District Agricultural Report depends upon the fullness of detail in which it describes climate, soil, &c.—those circumstances upon which, as well as upon agricultural skill, the character of farming depends*. This is sufficiently obvious; for the usefulness of a publication depends not merely on the quantity and accuracy of its contents, but upon the reader's ability to avail himself of the information it contains; the system of agriculture it describes may be admirably suited for the district, but if the circumstances under which it occurs be not fully stated, there is no evidence from which the reader may judge whether it be suited to those in which he is placed.

The Norfolk system of agriculture is certainly one which might be safely adopted over large districts in this country, but even here our remarks are true. A report of Norfolk farming would lose much of its usefulness and interest if no such detail of the geographical position, the climate and soils of the county, of the relation existing there between landlord and tenant, of the wealth of its farmers, were given—such an account as should help to explain the high estimation in which it is properly held. Mr Bacon enters into great detail on most of these points, indeed, the minuteness with which he gives the statistics of the district is tedious to the general reader. We shall extract some statements from his work, showing the condition of the county now, as compared with what it was half a century ago —

"The progress of production can be very fairly indicated by a reference to the comparative quantities of Wheat sold in Norwich Corn Market —

	Wheat No of coombs sold
1803	50,444
10	55,831
11	61,112
[illegible]	54 800
[illegible]	174,176
40	207 274
[illegible]	201,740
43	240 620
[illegible]	241,644

Outgoings of a Light land Farm in Norfolk, 1700 as compared [illegible]

					3	11	4½	
					1	15	11½	
					5	7	5	

Over large portions of the county this increased production was owing to the practice of claying or marling, which has greatly improved the light soils.

Mr. Coke, when he inherited his patrimony, exhibited no knowledge how great benefit was to be attained through the application of clay and marl to the surface soil, and its effects were so momentous that his example was immediately followed throughout the western part of Norfolk, and in some parts of the east. The consequence has been that no county, and certainly no district, exhibits to a greater extent the proof of this application, to be seen in the number of clay and marl pits which abound in every farm."

In the fen districts, where an immense improvement had arisen from this practice—

"The most general system of claying now adopted is, first to cut the land in ridges from fifteen to eighteen yards apart; the men then dig the holes in a straight line along the ridges; they get from eight to nine in a chain of twenty-four yards, the depth of the clay from the surface varies from five to nine feet; when it lies nearest the surface, about one and a quarter chalder of solid clay are raised from each of these holes, which costs about 6½d., including the spreading upon the land; but where it lies nine feet, as it frequently does in many parts of the fen, the ridges are made much nearer, for at that depth so much clay cannot be obtained as when it lies shorter, and the cost is about 10½d. to a 1½ per hair. Clay is not universally found, sometimes sand and gravel are found in the [illegible] usually mixed with strong blue gault, which [illegible] the west way. The rotation of crops adopted very rarely where the land has not been clayed; [illegible] enough and burn, and sow Colseed, which is fed off with sheep. In the spring it is sown with Oats [illegible] this crop is cleared off the land is manured and [illegible] Wheat. If it then laid down with [illegible] years. The third summer it is again [illegible] and so before. After claying, the plan [illegible] bone-dust or yard-manure for Colseed, which is fed off and Wheat sown; the next year Clover again succeeded by Wheat; this fallow or lay down to Grass for two or three years."

But doubtless much of the present fertility of the land is owing to the good yearly management of its tenants, as well as the adoption of permanent improvements—to the adoption of a good rotation of crops, and good husbandry generally, and to the consumption on the land by large numbers of sheep and cattle, not only of the green crop grown on it, but of large quantities of oil-cake. Upwards of 10,000 tons of this material are imported annually into the county; besides this, immense quantities of bone-dust, guano, nitrate of soda, &c., are used. One person alone sells 20,000 tons of the first annually; another sells nearly 3000 tons annually of the last, and of guano he last year sold 750 tons. It is by these means that the farmers of Norfolk have obtained for their county such a high position among the well-cultivated districts of the country.

Mr Bacon describes in detail the different branches of farming, as conducted in Norfolk, there are in his work chapters on Rotation of Cropping, General Culture, including accounts of the various crops, Manures, Marshes, Meadows, and Pastures Breeds of Cattle Sheep, &c, Feeding Horses, Implements, &c There is not room for extracts here, and we have no wish, by giving many, to keep our readers from, the work itself, but we cannot conclude without citing one passage, expressive of an opinion to the working out of which, under Mr Coke's patronage, we must attribute the eminence in agriculture which Norfolk has unquestionably attained among the counties of this country —

"'A large expenditure of money,' says a tenant occupier and an estate agent, 'is necessary to successful farming, and a tenant should always look for a guarantee in proportion to the outlay. An occupier who expects to hold his land but for a year, or to hold it only on such conditions as may terminate his tenure at the year's end, should expend so much only as he may hope to reimburse himself by a year's crop, for all expended beyond that might be thrown away, but such an expenditure plainly could not permanently improve the soil—so of three years, seven years, or any other short term The farmer, how rich soever he may be, will proportion his expenditure to his interest in the land, but let a tenant have a long and equitable lease, let him feel assured that he has a life-interest in a farm, and he will cast his whole lot with it, then if he be rich and skilful, he will cultivate it to the highest point to which the constantly improving state of agricultural science can direct him. Such is the importance to the whole nation of the tenant's guarantee.'"

On Landed Property, and the Economy of Estates, comprehending the Relation of Landlord and Tenant, and the Principles and Forms of Leases, Farm-Buildings, Enclosures Drains Embankments, Roads and other Rural Works—Minerals—and Woods. By David Low, Esq, F R S.E., Professor of Agriculture in the University of Edinburgh, &c. &c. Longman, Brown, Green, and Longmans.

We have the pleasure to announce the publication of this important work by Professor Low. It is one of the most valuable contributions to our Agricultural Literature which we have had an opportunity of noticing. We shall not fail, as soon as possible, to give our readers a particular account of its contents.

The Farmer's Almanac and Calendar for 1845. By the Rev. Thomas Dyer, and William Shaw, Esq. James Ridgway, Piccadilly, London.

It, indeed, is one of those publications which promises a great deal, but it misses the expectations which are not satisfied by an examination of the contents. Besides a good agricultural calendar, containing a deal of matter very useful and instructive to the farmer, has been gathered together in this volume [illegible] is a very interesting and readable addition to it. It certainly continues to be the best Almanac for the farmer that has appeared.

Miscellaneous.

Linseed as Food.—The only apparatus required is a Linseed-crusher, an iron copper, a hand-cup, a stirrer, one or two half-hogsheads, two or three pails, and a wooden rammer. These will cost about 12*l*. Large coppers are found inconvenient for stirring when compounds are made with the meal of Peas, Beans, &c. The [illegible] in use contain from 30 to 40 gallons. Upon large farms it will be desirable to have two—[illegible] than the other. The stirrer is an iron-ribbed spoon, fastened to a shaft of wood 4 feet long, and [illegible] less than the handle of a pick. The rammer is 3 feet long, about 5 inches square at the bottom, and 2½ at the top; through which a pin 14 inches long is placed for the convenience of being used with both hands; mine is nothing more than one end of a broken axle of a cart, with a stick thrust through the inch-pin hole. I commenced winter-grazing this year upon white Turnips grown after Flax, the tops of which, being [illegible] with Linseed-meal, were given to my bullocks according to [illegible] Upon every six pails of [illegible] I sprinkled [illegible] Linseed-meal in [illegible] while another [illegible] the Chaffins, the meetings being formed, a [illegible] placed close to the copper, and a bushel [illegible] Turnip-tops and straw put in; 2 or 3 [illegible] then poured upon it, and [illegible] mixed with a fork. Another bushel of the [illegible] chaff, &c. is next added, and 2 or 3 cups of [illegible] oil boiled, all of which [illegible] expeditiously mixed [illegible] together with the fork and rammed [illegible] pressed down as firmly as the nature of [illegible] will allow, with the latter instrument, which [illegible] the first layer. Another bushel of the Potentrew, chaffings, is thrown into the tub, the meetings, [illegible] before, and so on till the copper is emptied. The contents of the tub are lastly [illegible] over with a trowel, covered down, and in two or three hours the straw having absorbed the meetings, will also [illegible] Turnip-tops, have become partially cooked. This compound is then usually given to the cattle, but sometimes is allowed to remain till cold. The bullocks, however, prefer it warm, but whether hot or cold, they devour it with avidity. The cost for Linseed, according to the above rate of feeding, is 2*s*. 3*d*. per week. It will be seen that the real fattening properties of the above compound centre in the Linseed; and that, in order to produce a greater or less effect, it is only necessary to [illegible] this quantity of that important ingredient. [illegible], that Wheat, Oat, and Barley-straw, or Bean-chaff, may be used either with or without Turnip-tops, according to circumstances; nothing more being required than a [illegible] matter to act as a vehicle for conveying the Linseed to the stomach of the animal, and for receiving the [illegible] the mouth [illegible] mastication. Unfortunately for the [illegible] and few really practical agriculturists are disposed to [illegible] their own [illegible] published [illegible] opinion, however, the extract from the letter of a gentleman [illegible] whose enlarged and philanthropic views [illegible] long been acquainted, and who will rejoice [illegible] the complete validation of his own experience should in any way be [illegible] the [illegible] to his country —"My Flax-crop was pronounced by the Belgian agent, at Ipswich, to be as fine as any he had ever seen It was nearly 4 feet high, very thick in the ground, and perfectly free from weeds. The expenses for harvesting my crop were under 40*s*. per acre. I have laid 10 acres in [illegible] and 3 For the want of water I was not [illegible] to steep any; and shall not now make the attempt till the spring. My experiments with compound last year were satisfactory. I am now feeding 44 horses and colts with straw and hay compound My plan is, to 8 bushels of cut hay, and 8 bushels of Wheat chaff, are added 28 lbs. of crushed Linseed boiled in 10 pails of water I give the horses this quantity at night in the yard In addition, they have one pint of Pea meal per day, and one hundred weight of straw per week. The boiling Linseed is poured upon the chaff, and both are thoroughly mixed together. I intend giving my young stock 1½ lb. of Linseed-meal with a bushel of chaff daily; my cows the same."—*James Barker, Stour Hall, Romsey, near Harwich* A bushel of good Linseed at 5*s*. 6*d*., weighing 48 lbs is properly formed into compound with three or four times the weight of Peas, or any ordinary Wheat-meal, and a little more than double the weight of the whole in water, will cost about 24*l*. 8*s*. per ton.—*John Warner, on the Feeding Question*

How to Know Guano.—The farmer should never purchase guano, except its composition be guaranteed by the analysis of a competent chemist. He should go to no more than a half-pound sample of fifty land pounds than he buys, and if his crop should disappoint reasonable expectation, he should cause the samples to be analyzed and should the result not correspond with the analysis exhibited at the sale, he is fairly entitled to damages for the loss of his labour, rent, crop, &c. The necessity of following this advice will appear on considering the delusive, if not utterly false, analyses under which cargoes of guano have been too often sold. In a recent case which came under my cognisance, in consequence of having been employed professionally to analyse the identical cargo, I found the guano to be nearly rotten and after [illegible] containing altogether only 2½ per cent. of ammonia, ½ per cent of nitrate of ammonia, nearly 9 of sea-salt, 24 of water, and 46½ of earthy phosphates Now, this identical cargo of many hundred tons, fetched a high price at [illegible] sale, under the exhibition of the following analysis:—

Urate of ammonia, ammoniacal salts, and decayed animal matter	17 4
Phosphate of lime, phosphate of magnesia, and oxalate of lime	48 1
Fixed alkaline salts	10.8
Earthy and stony matter	1 4
Moisture	22.3
	100 0

The purchasers, I was told by the brokers, bought it

* See our last week's Leading Article.

readily, under a conviction that the guano contained 17·4 of ammonia, though the proportion of ammonia is not stated. By the following approximate analysis much guano has been sold:—Sand, earth, 35; lithic acid, &c., 15; carbonate and phosphate, 14; organic matter, 36=100. A gentleman informs that no sample of guano ever manufactured yet came of an amount of ammonia—a very valuable one, by-the-by—at present the state of combination in which the ammonia exists. It may contain at the moment 5 per cent. of the carbonate, but much guano-meat have been acted upon powerfully by humidity and will, therefore, contain little or no uric acid. In the very elaborate examination of guano by T. Oelkenher, apothecary at Innsbruck published at the request member of Buchner's "Repertorium of Pharmacy," we find, that if a glass rod dipped into aqua fortis acid be held over guano, strong fumes are developed; and the solution of guano has an alkaline reaction with litmus paper. These phenomena evidently indicate the presence of carbonate of ammonia, and of course a partially decomposed guano. *Ice* pound Chincha, and Bolivian guano *have* an acid reaction, proceeding from the predominance of phosphoric acid. Farmers frequently judge of the goodness of guano by the strength of the ammoniacal odour, but in this judgment they may egregiously err, for the *ammoniacal* guano has no smell of *ammonia* whatever; and it behoves to give out that smell only when it is more or less decomposed and wasted.—*Dr. Ure, in Pharmaceutical Journal.*

Notices to Correspondents.

RURAL CHEMISTRY.—By L. Reilly, Esq. F.R.S., Experimental Chemist to the Horticultural Society of London, Honorary Member of the Royal Agricultural Society, and Lecturer on Chemistry at the Royal Institution may be had [illegible] sellers, price 6s 6d.—"[illegible] Remarks on Chalking," shall appear next week. Many thanks to [illegible]

AVERAGES, &c.—*Gazette*.—We have by an estimate of the hay crop, and value of aftermath on several farms. The [illegible] stand thus:—

Crop 25 cwt.—Aftermath 14c		Crop [illegible] cwt.—Aftermath 12s	
" 30 " " 8s		" 30 " " 10s	
" 20 " " 16s.		" 15 " " 8s	

And so on.—The following is the estimated division of the gross produce in various districts among the three classes—Landlord, for Rent and Taxes; Farmer, for Interest, Profit, Labourers, &c.; Wages; and Expenses of Cultivation:—

Per Acre.

Crops Produced	Rent, &c.	Profit.	Labour	Gross [illegible]	Rent, &c.	Profit	Labour
[illegible]	[illegible]	[illegible]	[illegible]	[illegible]	24s	12s	19s 6d
20	2	10	18	30	24	14	11 0
25	2	10	13	37	24	20	6 0
30	2	10	18	45	24	17	12 0

45	2	10	18	67	24	15	20 10

If [illegible] distinct [illegible] owing to some of the distinct [illegible] [illegible] [illegible] [illegible] [illegible] [illegible] [illegible] being good but about [illegible] [illegible] [illegible] [illegible] [illegible] [illegible] [illegible]

SLATE FLOWER, SILKWORM, AND DIPLOMEY

THE following Articles, manufactured in Slate for Horticultural purposes, may be seen at Messrs. Norton's Cottage, upon application to the gardener (Mr. Hodges, adjoining the Nursery):

Tank Covers,	Bases for Balconies, Verandahs
Cisterns,	Orange Tubs, Flower Stands, &c.
Shelves,	
Garden Edging,	

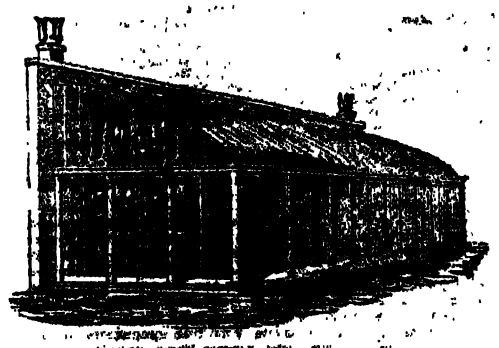
EDWARD JONES will be happy to [illegible] PERSONALLY or by POST.

MEALY BUG, THRIPS, &c. [illegible] Directions will effectually extirpate these pests; and in all quantities at 1s. and upwards each. [illegible] Address, with a remittance, [illegible] and MANNEL, Nurseryman, [illegible] Hurstbourne Priors, Hants, [illegible] of whom may be had, Cuttings of the choicest Melons, at 1s. per dozen.

[illegible] DRAWN.

E. L. BROWN'S [illegible] EXTRACT, for the [illegible] MEALY BUG, White and Brown Scale, [illegible] all other insects injurious to Trees and Plants in Hothouses, Greenhouses, &c. Orders punctually attended to, on receipt of a Post-office order for the amount. Manufactured and sold only by E. L. BROWN, Chemist, Leyton, Essex. Bottles, 1s. 6d., Half-pints, 2s., Pints, 3s., and Quarts, 5s., [illegible] for use. The above article [illegible] following [illegible] Mr. Fraser, Nurseryman, Ley Bridge-road, Leyton; Mr. John Lyle, Gardener to E. Barclay, Esq., Leyton; Mr. Lyndell, Gardener to W. T. Copeland, Esq., Bow, Middlesex, Essex.

HOT-WATER APPARATUS FOR HEATING HOTHOUSES, CONSERVATORIES, CHURCHES, AND OTHER BUILDINGS, upon improved principles, and at very moderate charges, erected by DANIEL and EDWARD BAILEY, [illegible]



D. and E. Bailey having devoted much time to the consideration of this subject, and had much experience in the erection of apparatus for the above-mentioned purposes, have, by improvements suggested in their practice, rendered their mode of heating not only very economical in its daily results, and have combined durability in the Apparatus with economy in the charge. They have erected apparatus in England, Scotland, and Ireland, for many noblemen and gentlemen, and have had the honour to be employed by the Horticultural Society of London, in executing the works of their splendid Conservatory lately erected at Chiswick.

D. and E. Bailey also construct in metal all descriptions of Horticultural Buildings and Sashes, and invite noblemen, gentlemen, and the public to an inspection of their various drawings and models, at 179, Holborn, where they have the opportunity of exhibiting, arranged on [illegible] an extremely complete and convenient kitchen [illegible] range, adapted for the continued supply of [illegible] water, and an arrangement of the oven more complete than has [illegible] been brought before the public.

D. and E. Bailey were also [illegible] to introduce [illegible] curvilinear houses to horticulturists, but can refer to the Conservatory attached to the Pantheon as one of their works, besides many others in this country and on the Continent.

D. and E. Bailey have prepared a quantity of the Galvanic Plant Protector, which are now ready for immediate delivery; they beg to introduce to public notice a new Tension Pipe, for Orchidaceous or [illegible] Houses, [illegible] economically, as at interval [illegible] may be used with [illegible] Manufactory.

CUTTAM AND HALLEN, ENGINEERS, IRON-FOUNDERS, &c., &c., No. 2, WIMBLEY-STREET, OXFORD-STREET, LONDON, and 26, CORNWALL ROAD, LAMBETH.

HOTHOUSES, CONSERVATORIES, &c., made upon the most approved principles, either of iron or of iron and wood combined, which can be fixed complete in any part of the Kingdom, at very low prices.

HOT-WATER APPARATUS for heating Hothouses, Conservatories, and Greenhouses; Churches, Public or Private Buildings, &c., with the [illegible] Improved BOILERS. After 15 years' experience, and having [illegible] upwards of 2000 Apparatus [illegible] above-mentioned purposes, and by various improvements [illegible] at the same time, C. and H. can with confidence [illegible] the adoption of Angular Apparatus upon the most economical [illegible]

Materials sent to any [illegible] who wish to fix their own Apparatus.

THE TANK SYSTEM on an improved principle, that will heat the house at the same time, without pipes.

IRON HURDLES, Best Wire for Strained Fencing, Ornamental [illegible] Garden Chairs, &c., &c., and every description of [illegible] for AGRICULTURAL and HORTICULTURAL Purposes.

Show Rooms [illegible] Factory, 3, Wimsley-street, Oxford-street, where [illegible] of the above can be seen.

STEPHENSON, [illegible] 61, Gracechurch-street, London, and [illegible] Street, Southwark, Inventors and Manufacturers of [illegible] COMMON and DOUBLE CYLINDRICAL [illegible] respectfully solicit the attention of scientific Horticulturists to their newly-improved methods of applying the [illegible] principle, to Forcing Houses, &c., by which extraordinary [illegible] with economical heat is secured to any required degree [illegible] the [illegible] pipes or flues. S. & Co. have [illegible] the support of numerous friends they [illegible] Copper; by which [illegible] as well as Copper, by which [illegible] are now as well [illegible] to those who have [illegible] be forwarded as well as [illegible] they may be seen in [illegible] Nurseries throughout the Kingdom.

S. & Co. beg to inform the Trade that at their Manufactory, No. 3, New Park-st., every article required for the [illegible] Horticultural Buildings, as well as for heating [illegible] may be obtained upon the most advantageous terms.

Conservatories, &c. of iron or wood, erected upon the most ornamental designs. Decorating, Painting, Glass, and Garden Fences, Wire Work, &c. &c.

GUANO for SALE, in Bags of 1 cwt. each, just [illegible] landed, with a procession of cargoes to follow, direct from [illegible] experience has unquestionably proved [illegible] first obtained, [illegible] and Mr. Skinner, [illegible] Peruvian Government. The only [illegible] to produce the results [illegible] for using that [illegible] are [illegible] which purchase will be given a warranted [illegible] of quality, and also a copy of the recently published Pamphlet [illegible] Practical Instructions for using Guano as a [illegible] by Practical Gentlemen.

Large quantity will be [illegible] from the ship at [illegible] promised; samples [illegible] and 26, Billiter-street, [illegible] at Stirling, additional [illegible] at Stirling, additional [illegible] street, Edinburgh, where [illegible]

LIQUID MANURE.

ENGLAND INDEBTED [illegible] THE, Attention of the [illegible] manufacturers of this [illegible] LIQUID MANURE, [illegible] with which many [illegible] prepared, by the use of [illegible] PUMP, is made at present for the purpose, [illegible] Breweries, Distilleries, and large Farmers; also Cisterns for Distillers, Brewers, Soap-boilers, and Tanners, [illegible] and sold [illegible] Pumps kept for hire; for Conveyancing and Malt Steepings heated by Hot Water, for Horticultural and many variety of manufacturing purposes.

The Pumps supplied on advantageous terms, by HAWKSLEY PUMP, Engineer, &c., 53, Dorset-street, Fleet-street, London.

IMPORTANT TO AGRICULTURISTS, &c.

ANALYSES of SOILS, MANURES, and all AGRICULTURAL PRODUCTS, are conducted by Messrs. MITCHELL and FIELD (late Mr. Mitchell), Analytical Chemists, with the view of ascertaining whether the Soil, in which it is proposed to grow any particular crop, contains all that is necessary to produce a luxuriant vegetation; also to estimate the relative value and purity of Manures, and the comparative worth of Farm Produce in general. Gentlemen instructed in Agricultural Chemistry. The course will comprehend the Elements of Analysis.—No. 54, Hawley-road, Kentish Town.

TANNER'S VITREOUS CLOTH, a SUBSTITUTE for GLASS for HORTICULTURAL PURPOSES.—The above recommends itself to the notice of Florists and Horticulturists, as producing effects superior to Glass, at a less expense. The support the Proprietor has received from very many highly respectable Florists encourages him to consider that his labours have not been misapplied in bringing before the public an article so generally required. Price of cloth, 7-8ths of a yard wide, thin, 2s. 6d. per yard.; stout, 3s. 1 yard wide, 3s. 6d. Price of Fluid (for renewing the cloth after lengthened service), 4s. 6d and 2s. 6d. per bottle. Manufactured only by N. W. TANNER, Chemist, Exeter; and Sold by Messrs. Butler and Muckley, Covent-garden, London; Mr. Cunningham, Paradise-street, Liverpool; Messrs. Lucombe and Pince, Exeter Nursery.

AGRICULTURAL DRAINING. — THE DERBY LEVEL.—The attention of persons Draining their land is directed to this efficient but simple Instrument, presumed to be all that can be required for the purpose, and its price such as to place it within the reach of all. To be had of the Maker,

J. DAVIS, Optician, Derby.

CHEAP AND DURABLE ROOFING.

BY HER MAJESTY'S

ROYAL LETTERS PATENT.

TO GARDENERS, NURSERYMEN, AND OTHERS.

F. M'NEILL & CO., of Lamb's Buildings, Bunhill-row, London, Manufacturers, and only Patentees of IMPROVED PATENT ASPHALTED FELT, for Roofing Houses, Sheds, Verandahs, &c., and for Protecting Plants, and Covering Garden Frames, beg to call the attention of Gardeners and others to their superior article, which has been exhibited at the Great Agricultural Shows of England, Scotland, and Ireland, and OBTAINED the PRIZE for being the best and cheapest article for roofing, &c. It has been tested in the gardens of several noblemen and gentlemen in the neighbourhood of London, and in different parts of the country, to whom reference can be made. The Felt is impervious to rain, snow, and frost, and a non-conductor of heat and sound. Its advantages are Lightness, Warmth, Durability, and Economy.—Price ONLY ONE PENNY PER SQUARE FOOT.

Samples, with directions for laying on, and testimonials as to its merits, sent free to any part of the town or country.—Patent Felt Works, Lamb's Building, Bunhill-row, London.

IMPROVED ROOFING FELT.

M'KIBBIN'S PATENT ROOFING FELT

Is particularly applicable as a Substitute for Slate, Zinc, Tiles, Thatch, and other Articles used for Roofing, from its Economy, Durability, and Lightness. It is quite impervious to wet and damp, resists the heat of the sun, and is a non-conductor of heat or cold. Besides the economy in repairs, the timber where it is used may be so light as to save its whole expense. It requires no other coating, and by attention to printed directions may be applied by a common labourer. It is free from breakage and contraction, does not [illegible] and requires neither painting nor coating. It is now in very general use for Roofing Houses, Verandahs, Sheds, Workshops, Aviaries, Railway Stations, Schhouses, &c. &c., and for protecting Plants, covering Garden Frames, Corn, and [illegible] Sheep-folds; and is [illegible] Portable Houses, Tarpaulin, and portable Rafts.

This [illegible] Slate, [illegible] than the common [illegible] other material, [illegible] and being [illegible] [illegible] and [illegible] perfect [illegible]

H. C. Bowman, Esq., Agent [illegible] Bunting Pitt.

It is with much pleasure [illegible] the materials [illegible] may do the superiority of your [illegible] with which I am [illegible] the greater cheapness [illegible] I have heard in its favour, and from the [illegible] extensively in Agricultural purposes [illegible] By lectures when on the [illegible]

(Signed) JOHN [illegible], M.D., Senior Lecturer on Chymistry, &c., [illegible] Agriculture and Rural Economy [illegible]

Sold in sheets 32 inches by 20, at 2s. each (being less than 1d. per square of 100 feet).

Apply to H. C. BOWMAN,

Agent to the Manufacturers,

No. 16, East India Chambers, Leadenhall-street, London.

WHITNEY'S PATENT CLOTH for COVERING GREEN-HOUSES, CUCUMBER or MELON PITS, &c. This Cloth is made expressly for the purpose of applying Whitney's Composition upon, and is much more durable than any other material; when coated it is beautifully white and transparent. The perfect [illegible] of Whitney's Composition for all Horticultural purposes [illegible] be more fully established than [illegible] that on the 1st of April last, a Black Hamburgh Vine was [illegible] a house, the [illegible] trained into a house covered with Cloth, and coated with Composition. On the 1st of Sept. [illegible] the Grapes, 16½ ounces, the fruit was [illegible] pronounced to be excellent. A [illegible] by the Editor of the Gardeners' Chronicle [illegible] very luxuriantly, the foliage [illegible] exceedingly well. As a winter protection [illegible]

The [illegible] DESCRIPTION can be obtained of Messrs. Butler & Muckley, Covent-Garden Market; Hurst & M'Laird, [illegible] Warner, Cornhill; Barclay & Sons, [illegible] and Hannay & Co., Oxford street; [illegible] Bailey, Wolverhampton.

BURBIDGE AND HARRIS'S COOKING APPARATUS, combining [illegible] This Cooking Apparatus is believed to [illegible] advantages than any yet submitted to the public, both economy in the [illegible] of material and workmanship; in fact, the laws of [illegible] are applied as to produce the greatest effect with the least consumption of fuel, without destruction to the apparatus; and B. and H. can safely recommend it from experience, as unquestionably superior to anything of the kind hitherto made. [illegible] may be forwarded, upon application, detailing particulars and prices, to 130, Fleet street.

LEA AND PERRINS'S WORCESTERSHIRE SAUCE Prepared from the Recipe of a Nobleman in the County.

"*Great Western Steam-Ship, June 6, 1844.*—The cabin of the Great Western has been regularly supplied with LEA & PERRINS'S Worcestershire Sauce, which is adapted for every variety of dish, from turtle to beef, from salmon to steaks, to all of which it gives a famous relish. I have great pleasure in recommending this excellent Sauce to Captains and Passengers, for its capital flavour, and as the best accompaniment of its kind for a voyage. (Signed) JAMES HANNAM."

"One of the most piquant [illegible] and luxurious and epicurean ages is [illegible] Worcestershire Sauce, adapted to fish, flesh, fowl, and [illegible] zest far superior to the long-established favourites; [illegible] wholesome kind of less cost."—*Naval and Military Gazette*, April [illegible], 1844.

Sold Wholesale by the Proprietors, Messrs. LEA and PERRINS, Worcester; Messrs. BARCLAY and SON, Farringdon-street; and the principal Oil and Italian Warehousemen in London; and Retail by the usual venders of Sauces.

IMPORTANT to the [illegible] WORLD.—By far the most influential of all the causes that contribute to personal adornment is the Hair. Its frequent, [illegible] and improvement, proportionally occupies the attention of our fashionable circles, and any [illegible] which will [illegible] desirable results will be [illegible] an immediate [illegible] The following [illegible] from the [illegible] a gentleman [illegible] Bridlington, will be read with the [illegible] interest:—

"A lady, a [illegible] of mine, has found great benefit from the use of your Balm. About six months ago her hair nearly all fell off. I recommended her to [illegible] which she did. In the course of [illegible] ceased to fall off. Before she had [illegible] to grow very profusely, and she has now a very [illegible] head of hair. "I am, gentlemen, yours respectfully,

"WM. SMITH.

"Chemist and Druggist, Market-place, Bridlington.

"To Messrs. C. and A. Oldridge.—March 18, 1844."

C. and A. OLDRIDGE'S BALM of COLUMBIA causes the Hair to curl beautifully, frees it from scurf, and [illegible] falling off, and a few bottles generally restore it [illegible] prevents grayness. 3s. 6d., 6s., and 10s. [illegible] prices are genuine.

OLDRIDGE'S [illegible], 7, Wellington [illegible] from the Strand.

HORIZONTAL WATCHES, SAVORY and MOORE, [illegible] opposite the Bank. Price, in silver cases, three and a half guineas each; or in gold cases, six guineas each. These Watches are accurate and durable, the horizontal escapement, being peculiarly suited to combine those important requisites. They are jewelled in four holes, and continue going whilst being wound. A twelvemonth's warranty given with each.

PATENT ELECTRO-PLATED AND GILT ARTICLES in every variety, at the Manufactory of the Patentees, ELKINGTON and Co., [illegible], Regent-street, corner of Jermyn-street; also [illegible] Moorgate-street. The Patent Electro processes being extensively carried under their licence, the Patentees beg to state [illegible] confine their own manufacture to goods of a superior and guaranteed quality only, which invariably bear their mark, Elkington and Co. [illegible] Old articles replated and gilt.

ELECTRO-PLATING AND GILDING.—OLD PLATED GOODS RESTORED and made equal to new by Messrs. ELKINGTON and Co.'s Patent Process. The process being carried on in London only by Messrs. Elkington and Co., it is particularly requested that all goods may be forwarded direct to their Establishment, 22, Regent-street (corner of Jermyn-street), or 45, Moorgate-street, City. New goods Plated upon White Metal in great variety. Books of Prices and Drawings sent to all parts of the Kingdom and abroad free.

REAL SHEFFIELD PLATED DISH COVERS, at prices hitherto unattempted. THOMAS WEST, 18, Ludgate-street, London, having received a large supply direct from the manufactory at Sheffield, offers the best Meat Dish Covers, as follow.—Cottage Pattern—1 Cover of 10 inches, 2l. 12s.; 1 do. of 12 inches, 2l. 8s.; 2 do. of 14 inches, 4l. 8s.; the set of 4, complete, 11l. 12s. ONLY. Double Bone Pattern—1 Cover of 10 inches, 4l. 16s.; 1 do. of 12 inches, 3l. 19s.; 2 do. of 14 inches, 3l. 4s.; the set of 4, complete, 14l. ONLY. In noticing the prices of the above goods, T. W. ventures to assert they are superior to many advertised at a much higher price. Best Wrought Silver Spoons and Forks as usual, Fiddle Pattern, 7s. 3d. per oz. Queen's Pattern, 8s. 3d. per oz. Superior Watches and Fine Gold Jewellery. Illustration [illegible] in London. Weekly Handbook, 16 Engravings, and full of useful information, is just published, and may be had gratis, and post free, on application to T. West, Silversmith, 18, Ludgate-street, London.

OBTAINABLE FOR NOTHING. — The Nervous are respectfully invited to send to Rev. Dr. WILLIS MOSELEY, 9, Clarendon-street, Somerstown, London, for the small Pamphlet just published, on the most successful treatment of Nervous or Mind Complaints, by which he cures these Diseases as certainly as water quenches fire, which Pamphlet he will return, if a stamp is inclosed, free of charge.

NATIONAL ASSURANCE
TO 82, PALL MALL.
ACTUARY—PETER GRAY, Esq.

Postage Stamps, Post-office Orders, &c., sent to the Secretary, MR GEORGE WANSEY, Solicitor, 2, Moorgate street, London, will be duly acknowledged.

In one thick vol., a New Edition, being the Ninth, much enlarged, price 16s.,
MODERN DOMESTIC MEDICINE: A POPULAR TREATISE, exhibiting the Symptoms, Causes, and most efficacious Treatment of Diseases; with a Collection of Approved Prescriptions, Management of Children, Doses of Medicines, &c. Forming a comprehensive Guide for the Clergy, Families, and Invalids. By T. J. GRAHAM, M.D., &c. "It is evidently the result of great professional talent, experience, and judgment; the author everywhere appears conscientious and candid. *One object* is prominently evident—a sincere desire to benefit his suffering fellow-creatures. To recommend a work alike the present to our readers, is only to manifest a proper regard for their welfare."—*Literary Journal*, Feb. 1843.
"It is altogether deserving of permanent popularity."—*London Weekly Review*.
SIMPKIN & Co., Paternoster-row; HATCHARDS, 187, Piccadilly; and TEGG, 73, Cheapside. Sold by all Booksellers.
Also, by the same Author, in 8vo. price 11s., Third Edition, enlarged,
2. ON THE DISEASES OF FEMALES: a Treatise, illustrating their Symptoms, Causes, Varieties, and Treatment. With numerous Cases, and a Medical Glossary. Including the Diseases, and Management of Pregnancy and Lying-in.
"It contains a mass of information indispensable to those for whom it is intended, and embraces, in value any other book of its character."—*Blackwood's Lady's Magazine*.

NEW WORK ON AGRICULTURAL CHEMISTRY.
Just published, in 1 vol. post 8vo., 7s. 6d. cloth lettered,
LECTURES to FARMERS on AGRICULTURAL CHEMISTRY. By ALEXANDER PETRIE, D.P.
Containing Introduction, Atmosphere, Water, Soil, Constituents of Plants, Sources of the Carbon of Plants, Oxygen, Hydrogen, and Nitrogen of Plants, Inorganic Constituents of Plants, Ashes of Plants, Fallow, Rotation of Crops, Manures, Vegetable Manure, Animal Manures, Mineral Manures; Appendix, Gumo.
"The author does not overload his subject with needless details, which is the vice of some such books, but he confines the reader to those points only which he ought to be well acquainted with, and these he explains in a clear and simple way."—*Gardeners' Chronicle*.
Printed for TEGG and WAKSEY, 85 Upper Gower-street.

HEATING BUILDINGS BY HOT WATER.
Now ready, Second Edition, greatly enlarged, with numerous woodcuts, &c., 8vo, price 10s. 6d. cloth,
A PRACTICAL TREATISE on WARMING BUILDINGS by HOT WATER; on Ventilation, and the various Methods of Distributing Artificial Heat, and their Effects on Animal and Vegetable Physiology. To which are added an Inquiry into the Laws of Radiant and Conducted Heat, the Combustible Constitution of Coal, and the Combustion of Smoke. By CHARLES HOOD, F.R.S., F.R.A.S., &c.
WHITTAKER AND Co., Ave Maria-lane, London.

JUST PUBLISHED,
AN ESSAY on the Latest Improvement on the Culture of Wheat Sowing, Drilling, &c; also of Barley, Beans, Peas, Seeds, &c., (and for Gardeners and Nurserymen's purposes invaluable, as the land is cleared at much less expense from weeds, &c.), being a great saving in seed and producing greater crops, by adopting the new principle, and which is suitable to all soils. And a small model, with full instructions to make the same, at the cost of 14s. to 15s. Gypsum for land, and for staying the ammonia, &c., in Manure-hills, Stables, Cow-sheds, &c. &c. &c., supplied genuine, in any quantity, from the principal works in the United Kingdom, to suit the parties convenience, effected in 12 hours, will be forwarded, postage free, on receiving 1s. by letters prepaid, addressed to J. WOOLLCOCK, 3, Pepper-street, City of Chester.

NOW READY FOR DELIVERY,
JOHNSON AND SHAW'S FARMERS' ALMANAC AND CALENDAR, for 1845, 200 pages, and 100 Engravings of the best Agricultural Implements, with their prices and Makers' names, &c., &c. Price only 3s.; sent
1. JOHNSON'S TRACTS for Agricultural Schools, Cottage Farmers' Assistant, Farmers' Calendar, and Agricultural Chemistry, 1s. each.

READ the following TESTIMONIAL in favour of PARR'S LIFE PILLS, which is sufficient to convince the most prejudiced person that they are all that is required to conquer disease, and, consequently prolong life:—"To T. Roberts & Co.—Sirs,—I beg to hand you the following Testimonial, which I have just received from Mr. Williams, Union-street, Nottingham.—Yours, obediently, G. BATTERS, Chapel-bar, Nottingham.
"Sir,—Printing is a great blessing to mankind, for now I am enabled to make known, through your's perfect cure, by taking PARR'S LIFE PILLS, of extremely bad indigestion, a Bilious disorder, and Sick Headache, which I have been subjected to for years; and money enough has been paid to physicians and surgeons, which now would have been a little fortune to me. I wish every fellow-creature clearly to understand that I was wonderfully relieved by taking one box of PARR'S LIFE PILLS. Accident threw a testimonial in my way of a miraculous cure of a bilious attack and sick headache. The second box enabled me to go about my business with spirit and alacrity, and by taking two or three more boxes, I am happy to add my humble testimony of a perfect cure of that dreadful disorder—Bilious and Sick Headache, which rendered me, before I took PARR'S LIFE PILLS, unfit for business. Considering the loss of time and pain, my case would find that one box of PARR'S LIFE PILLS is worth, instead of 1s. 1½., as many guineas. May all persons make trial of PARR'S LIFE PILLS, in the manner with G. yours, thankfully,
"To Mr. G. Batters. G. WILLIAMS, Union-st., Nottingham."
PARR'S LIFE PILLS are sold by all respectable Medicine Venders. See the Words "PARR'S LIFE PILLS," in White Letters on a Red Ground, on the Government Stamp.

Printed by WILLIAM BRADBURY, of No. 6, York-place, Stoke Newington, and FREDERICK MANSFIELD EVANS, of No. 7, Charles-row, Stoke Newington, both in the county of Middlesex, Printers, at their Office in Lombard-street, in the parish of St. Mary-le-Bow, in the City of London; and published by them at the Office, No. 5, Chancery-lane, in the parish of St. Dunstan-in-the-West, in the said county of Middlesex. All Advertisements and Communications are to be addressed to the Editor. Saturday, November 23, 1844.

ROSES.

MESSRS. LANE AND SON, Great Berkhampstead, Herts, have an extensive and well-grown Stock of Standard and Dwarf Roses, which they are enabled to offer at the following prices, the selection being left entirely to themselves, viz.:—

DWARFS, good old sorts without names, on own roots . . . . . 30s. per 100
Ditto with names, in pairs, on own roots 50s. per 100
Ditto superior ditto . . . . 12s. to 30s. per doz.
STANDARDS, first rate . . . . 10l. per 100
Ditto ditto . . . . 24s. to 30s. per doz.

They have also an immense Stock of Roses in pots for greenhouse culture, at from 18s. to 30s. per doz. Likewise numerous others at a much lower rate, but which they could not confidently recommend.

Rose Catalogues for 1844-5 may be had on application to the Nurseries, inclosing a 2d. postage stamp.

Great Berkhampstead, Nov. 30, 1844.

ENGLISH OAKS FOR TIMBER.—THE TRUE QUERCUS SESSILIFLORA AND Q. PEDUNCULATA.

W. JACKSON & Co. beg most respectfully to call the attention of the Nobility, Gentry, and Planters in general to the above valuable Trees, of which they possess a fine healthy stock, grown from Seeds carefully collected from their own timber-trees. Two years' Seedlings, 6s. 6d. per 1000. Transplanted, 1 to 1½ ft., 1½ to 2 ft., 2 to 3 ft., and 3 to 4 to 6 ft.; Prices with every other particular will be given on application. Carriage paid to Newcastle, York, and London, when ordered in large quantities.

Cross Lanes Nursery Office, Bedale, Yorkshire, Nov. 30.

GERANIUMS AT VERY LOW PRICES.

WM. E. RENDLE, having a large stock of the following sorts of GERANIUMS, is enabled to offer them at very low rates.

*** A dozen will be forwarded on receipt of a Post-office order, including hamper, package, and carriage free to the Exeter terminus of the Great Western Railway.

CLASS 1.—30s. per dozen, including package, carriage, &c.—Lady Villiers, Fascination, Thunderer, Oberon, Favourite, Prince of Waterloo, Jessie, Count D'Orsay, Lord Ebrington, Constellation, Lavinia, Cornish Gem, Attila, DUKE OF CORNWALL, Sunrise, and Modesty.

CLASS 2.—20s. per dozen, including package, carriage, &c.—Evelina, Gipsey, Witch, Hamlet, Cynthia, Aurora, Creole, Lady Cotton Sheppard, Countess of Mount Edgcumbe, Fair Maid of Devon, Wonder of the West, Portia, Jupiter, Life-guardsman, King John, Sultan, and Princess Royal (Lyne).

All the plants are strong, healthy, and well established, and will be forwarded immediately on receipt of order.

Union Road Nursery, Plymouth, Nov. 30, 1844.

BAGSHOT NURSERY, SURREY.

JOHN WATERER begs to call the attention of the Nobility, Gentry, and Public, to his unlimited collection of AMERICAN PLANTS, which are this season unusually well set with bloom buds, particularly those for forcing, comprising,—Rhododendrons, Kalmias, Azaleas, Andromedas, Lelums, Daphne cneorum, &c. Also those of larger sizes, among which may be had Rhododendron Catawbiense, and many other fine varieties; Kalmia latifolia, Magnolias, of sorts; Azalea occidentalis major, and varantia, &c. &c., from 2 to 6 feet, which are fine objects for single specimens or borders, being bushy to the ground. J. W. begs to recommend his unrivalled Stock of Cedars of Lebanon, 18 inches to 4 feet; also about 200, 4 to 9 feet, bushy to the ground, very handsome for Lawns; the whole of them warranted to move safely. Also about 5000 Spanish Chesnuts, 4 to 6 feet; 30,000 Larch Firs, 2 to 4 feet; 20,000 Birch, 3 to 4 feet; the whole of which may be had at moderate prices. N.B.—Planting done by contract.

Nursery, Bagshot, Surrey, 24 miles from Farnborough Station, South Western Railway.

THE TRUE FASTOLFF RASPBERRY.

GREAT YARMOUTH NURSERY. NORFOLK, 1844.

PATRONISED BY HER MOST GRACIOUS MAJESTY THE QUEEN, HIS GRACE THE DUKE OF RUTLAND, HIS GRACE THE DUKE OF MARLBOROUGH, THE EARL OF HARRINGTON, THE EARL OF LIVERPOOL, THE LORD BISHOP OF LONDON, LORD VISCOUNT LORTON, LORD SONDES, &c. &c.; as well as by the HORTICULTURAL SOCIETY OF LONDON.

YOUELL AND CO. beg to announce they are again able to supply fine canes of the above truly excellent variety, uncqualled for the size of its Fruit and richness of flavour; prices as follow:—

Packages containing	100 Canes	£2	0 0
Ditto	50	1	1 0
Ditto	25	0	12 0

YOUELL AND CO. take the present opportunity to state that the above unequalled RASPBERRY is to be obtained only at their Nursery or of their Agents, a list of whom appeared on the Advertising Sheet of last week's *Gardeners' Chronicle*; and they recommend their friends to be cautious of whom they purchase, as another Raspberry, under the above title, has been substituted by certain parties as the "true variety."

Great Yarmouth Nursery, Nov. 30, 1844.

TO MELON GROWERS.

FISH'S EARLY CANTALOUPE and HARDY GREEN-FLESH MELONS. The above are recommended to all Melon-growers, as, independent of the good quality of the Fruit, they are so hardy as to require comparatively little attention; a fact of considerable importance where fuel is expensive, and fermenting material a scarce commodity. Both sorts were awarded Certificates of Merit at Regent-street, London; the Cantaloupe on the 7th of May, described as "good early fruit;" and the Green-fleshed on the 4th of June, described as "capital green Melon, highly fragrant, and weighing nearly 5 lbs." The Cantaloupe grows from 4 to 6 lbs. in weight. Fruit was exhibited in July at Chiswick, weighing 4 lbs. 14 oz., and the fifth crop is maturing in November, from the same plants cut from in May. Specimens of the Green-fleshed, from the same plants cut from in June, were exhibited at Regent-street, on the 1st Oct., weighing 3 lbs. each. These have been grown on dung beds, as described in the *Chronicle* of the 7th May and 1st October.

YOUELL and Co. having purchased of Mr. Fish the entire stock of Seed of the above most desirable Melons, for the first time offer it to growers, being fully confident of its realising all the merits ascribed to it. Sealed packets, containing three seeds of each, 6s., sent per post, free.

Great Yarmouth Nursery, Nov. 30, 1844.

THE FILBY, or FASTOLFF RASPBERRY.—At the request of some gentlemen living in the neighbourhood of Yarmouth, T. RIVERS begs to submit the history of this really excellent Raspberry to the public. In the year 1814 Colonel Lucas, of Filby, a place lying between Norwich and Yarmouth, discovered a Raspberry plant growing under an old Laurel hedge in his garden. His attention was drawn to it, and he soon found it to be a superior and delicious variety, so that in a short time every other sort was ejected from his garden, and this alone cultivated. It was not, however, till 1824 that he allowed his gardener to part with it, who then gave canes to his neighbours, and by this means it got to be cultivated in Calstor, Ormsby, and, in fact, in all the neighbourhood, under the name of the FILBY RASPBERRY, to the exclusion of all other sorts. It has latterly often been called the Calstor Raspberry, from the Market Gardeners growing it in that parish. In Caistor is an old castle in ruins, that formerly belonged to the Fastolff family: the latter name was given to the variety by YOUELL and Co., when they first began to sell the canes. The fruit upon which Dr. LINDLEY pronounced his opinion was gathered in the Filby garden, now the property of the Rev. G. LUCAS, who authorises and permits the publication of the above facts; and has also permitted his Gardener to supply the Canes after this date to T. RIVERS only.

Canes are sold at 30s. per 100, or 6s. per score, carriage paid to London. Charge for package, for small parcels, 6d., for large do., 1s. to 1s. 6d. Orders to any amount can be executed. The Trade price will be given on application.

Sawbridgeworth, Herts, Nov. 30, 1844.

JOHN BELL begs to inform the Public he has a Large Stock of Strong VINES in pots, 2 and 3 years old, from Eyes, at the following prices:—

Strong 2 year old Plants in Pots		5s. 6d.
,, 3 ,, ,, ,,		7 6
Very Strong Fruiting ,, ,,		10 6

FASTOLFF RASPBERRY.

J. BELL begs to correct the statement in the *Gardeners' Chronicle* two weeks since, respecting the above Raspberry having been originated in W. Jary, Esq.'s garden, at Burlingham. It was first discovered in Col. Lucas's garden at Filby, as stated by Mr. Rivers, and the first canes of it given to Mr. Perfect, gardener to W. Jary, Esq., by Mr. Reynolds, the then gardener at Filby.

J. B. begs to assure his numerous friends, whom he has supplied with Canes of the above Raspberry, that they may rely on their being the True Fastolff, and that no spurious sort is known about this part of the country, as stated in the Misses. Youell's Advertisement last week.

Horticultural Establishment, Brasenose-seed Warehouse, 3, Exchange-street, Norwich.

IMPORTANT TO PLANTERS.
ILEX OR EVERGREEN OAK.

W. E. RENDLE has a large Stock of this most valuable hardy tree, and can supply fine two-year old Seedlings, from seed-pans, at 20s. per 1000, package and carriage free to the Exeter terminus of the Great Western Railway.

Union Road Nurseries, Plymouth, Nov. 30, 1844.

SUCCULENTS FOR SALE.

WILLIAM MASTERS, of the Exotic Nursery, Canterbury, is instructed to sell, in one lot, by private contract, a very Excellent Collection of SUCCULENTS, the property of a gentleman who is about to discontinue their culture. To a person wishing to possess a collection of these interesting productions, this collection offers many points of attraction. The plants are healthy; the number of species considerable, and the price moderate.

For particulars inquire of Mr. MASTERS, Exotic Nursery, Canterbury.

LYNE'S GERANIUMS.—See the FLORISTS' JOURNAL FOR NOVEMBER 1844.

Coloured Engravings of PRINCESS ALICE and WHITE PERFECTION, which, with CONFIDENCE and REDWORTH, are now sending out at 21s. each.

WM. E. RENDLE, Union-road Nursery, Plymouth, Nov. 30.

PLANTING SEASON.

W. ROGERS AND SON, NURSERYMEN, CONTRACTORS, PLANTERS, & LANDSCAPE GARDENERS, Southampton, beg respectfully to notify that their Nursery Stock is this season unusually fine, and from the extent of their grounds they are enabled to execute orders to any amount, and at the lowest price; delivered free of carriage (if ordered in quantity) per railway to London, or by steam-vessels coastwise.

SEEDLING.

Ash, 1 yr., 1s. 6d. } per
,, 2 yrs., 2s. 6d. } 1000.
Beech, 1 yr., 2s. } per
Birch, 1 yr., 2s. } 1000.

Sea Pine (Pinus maritima), excellent for nurses or exposure to the sandy sea-shores of Scotland or Ireland, 1 yr., 2s., 2 yrs., 7s. 6d. per 1000.

Oak, the true "Durmast" of the New Forest (Quercus sessiliflora), producing timber of the largest dimensions, and decidedly the most valuable species of the English Oak, 1 yr., 7s. 6d., 2 yrs. 10s., 3 yrs. 15s. per 1000.

If 100,000 of any one sort is ordered, a deduction from these prices will be made.

TRANSPLANTED.

Prices and samples of the various sizes may be had on application.

Alder	1	2	ft.	Oak, "Durmast," English	1	2	3 ft.
Beech	1	2	4 ft.				
Birch	1	2	4 ft.	Turkey	1	2	5 ft.
Ash	1	2	5 ft.	Spruce	1	2	6 ft.
Spanish Chesnut	1	2	6 ft.	Larch	1	2	3 ft.
Elm	1	2	5 ft.	Scotch	1	2	4 ft.
Poplar, Blk. Canada	2	4	6 ft.	Pinaster	1	2	3 ft.
				Sea-Pine	1	2	4 ft.

PLANTS FOR COVER OR UNDERWOOD.

Rhododendron ponticum, 1 to 2 inches, 20s. to 30s. per 1000.
Ditto, 2 to 4 inches, 40s. to 50s. per 1000; 4 to 6 inches, 60s. to 80s. per 1000; 1 foot, 20s. per 100.
Mahonia aquifolia, 40s. per 1000. Game are remarkably fond of the fruit of this plant, which is also a handsome flowering Evergreen.
Common Laurel, 20s. to 40s. per 1000.
Comewell Willow, 40s. per 1000. (Best for Underwood.)
Furze, 10s. per 1000. Broom, 10s. per 1000.
Elder, common black, 8s. per 100. Excellent for sea embankments. Tamarisk, 8s. per 100.

MISCELLANEOUS.

A great Stock of Forest and Ornamental Trees of large growth, from 6 to 10 feet, adapted for immediate effect.
Single Camellias, from pots, well rooted, 50s. to 75s. per 100.
Rose stocks, 8s. per 100, from cuttings of the Bourbon De Lisle, on which all kinds take freely by buds and grafts, and may be grown in the smallest sized pots.
Double Furze, 25s. per 100. Forms a beautiful flowering hedge.
Double Red Thorn; Double White do.; Single new crimson, 30s. per 100. Sea Pine, from pots, 40s. per 100.
Ribes sanguineum, 12s. 6d. per 100. Kalmia latifolia, 40s. per 100.
Printed Catalogues and Prices of their general stock may be had. Gardeners of experience and ability recommended.

CHEAP AND GOOD PELARGONIUMS.

W. MILLER has several thousands of good Plants of the very best PELARGONIUMS, selected from those exhibited by the most successful raisers:—as, Foster, Garth, Beck, Lyne, Gaines, Wilson, Thurtell, Catleugh, and others; and can be well recommended as good additions to small or large collections, and will be sold, at low prices, by the dozen. A select list may be had on application.

W. M. has also a few more sets of those splendid new seedling Pelargoniums raised by G. M. Hoyle, Esq., Guernsey; also some packets of Mr. Hoyle's choice Seed—5s., 7s.; 10s., 12s.—Providence Nursery, Ramsgate.

NURSERY LARCH.

COWAN AND CO., NURSERYMEN, Glasgow, have on hand a large quantity of well grown transplanted LARCH, 2 and 3 feet high, which they will sell at a low price, as they must be removed this season. All sorts of Forest-trees, seedling and transplanted, grown extensively, and offered at very moderate prices.

NURSERY STOCK.

RICHARD MITTON, NURSERYMAN, Pontefract, being about to clear off five Acres of Nursery Stock, consisting of Forest and Fruit-trees, Evergreen and Flowering Shrubs, &c., begs to offer the same at unusually low prices. Particulars may be had on application.—Pontefract, Nov. 29.

J. B. SMITH, having purchased the rare and valuable STOCK-IN-TRADE of the executors of his late father, begs leave to inform the Nobility, Gentry, and Amateurs, that he intends carrying on the Business as hitherto, and shall be glad to be favoured by their kind commands, which shall ever meet his best attention. A choice collection of Rhododendrons, Azalea Indicas, Hardy Azaleas and Ghent Azaleas, Camellias, Roses, Pelargoniums, Liliums, &c., including the most novel and approved varieties; a priced list of which may be had on application. A liberal discount for cash. A remittance or reference from unknown correspondents is solicited.

Norbiton Nursery, Kingston, Surrey, Nov. 30.

CONIFERÆ.—The Subscribers have this season to offer the following:—

Edinburgh, Nov., 1844.

TULIP SEED, &c.

HENRY GROOM, CLAPHAM RISE, near London (removed from Walworth), BY APPOINTMENT FLORIST TO HER MAJESTY THE QUEEN, and to HIS MAJESTY THE KING OF SAXONY, having observed in the Leading Article of the *Gardeners' Chronicle* of Nov. 16, a notice of raising TULIPS from Seed, he begs to state that he has saved a large supply of Seed this season, which can be had in packets at 5*s.* each. He also begs to offer the following articles:—

		£.	s.	d.
100	TULIPS, in 50 fine sorts, with names	5	0	0
	Superfine mixtures, 21*s.* per 100.			
100	RANUNCULUSES, in 100 superfine sorts, with names	2	10	0
	Superfine mixtures, 10*s.* 6*d.* to 21*s.* per 100.			
100	ANEMONES, in 100 superfine sorts, with names	2	10	0
	Superfine mixtures, 10*s.* 6*d.* per 100.			
25	AURICULAS, in 25 superfine sorts, with names	3	3	0
25	pair of CARNATIONS, in 25 do. do.	2	10	0
25	pair of PICOTEES in 25 do. do.	2	10	0

LILIUM LANCIFOLIUM ALBUM, good bulbs, 2*s.* 6*d.* each.
,, ,, PUNCTATUM ,, 7*s.* 6*d.* ,,
,, SPECIOSUM, true ,, 52*s.* 6*d.* ,,
Foreign orders executed.

KNAP HILL AND BAGSHOT NURSERIES.

NOTICE.—The Business of these Nurseries, since the death of the late Michael Waterer, carried on in the name of H. and J. WATERER, is by mutual agreement divided. The KNAP HILL NURSERY will in future be carried on by HOSEA WATERER, and that at BAGSHOT by JOHN WATERER. It will, therefore, be of importance, to prevent confusion, that correspondents be particular in the address, and direct letters intended for the Knap Hill Nursery, to HOSEA WATERER, Knap Hill, near Bagshot: and those for the Bagshot Nursery, to JOHN WATERER, Nurseryman, Bagshot, Surrey.—November 30.

SHILLING'S EARLY GROTTO PEA.

THE above PEA possesses advantages over every other for autumn sowing, being quite hardy, very prolific, and much larger than any other early Pea. See *Gardeners' Chronicle*, 25th of last May. "Mr. Shilling has sent us specimens of his new Early Grotto Pea, which were gathered on the 20th inst. He states that these were produced from seed sown in the open ground on the 25th of last November. Judging from the specimens sent, this is a fine, large, good-looking Pea, and will, no doubt, be found to be a very useful early variety."

To the Market Gardener they will be found invaluable. Price 1*s.* 6*d.* per quart, 12*s.* per peck.

SHILLING'S QUEEN CABBAGE, which gave such general satisfaction last year, as the best early variety grown. Having saved a considerable quantity of seed this summer, it is offered on the following advantageous terms:—1*s.* 6*d.* per oz., 20*s.* p. lb.

Agents—Messrs. Field and Child, 119, Lower Thames-street; Messrs. J. and W. Noble, 152, Fleet street; Mr. J. Keynes, 4, Great Russell-street, Covent Garden; Messrs. Hurst and Mr. Mullen, 6, Leadenhall-street, London.

Northamptonshire Nursery, Odiham, Hants.

ADDRESS TO THE PLANTERS OF ENGLAND.

TRUE HIGHLAND PINE-TREE.

MY LORDS, LADIES, AND GENTLEMEN,—The time has come, when all those who have waste lands at their disposal should plant them. Of this I am fully persuaded, and I beg you will allow me to explain on what grounds this opinion is founded. England, generally, is a thickly-wooded country, yet, strange though it may appear, it has not been planted with any view to meet its most urgent wants. If the poor farmer require an outhouse built for his cattle, he cannot have it because there is no dead-wood in the neighbourhood: he builds it therefore of wicker, or of any other rubbish he can lay hold of. Instead of having plenty of firewood on all hands to fence young hedges, planted like other things on the common surface of the ground, military-like fortifications have been raised to divide fields, occupying as much good land as is contained in three of the largest counties of Britain: it is on those banks ineffectual attempts have been made to grow hedges. After the 1st of March, when the Royal Agricultural Society's prize on fences shall have been awarded, a great proportion of the hedges throughout England will be reconstructed by planting them on the plain surface; and the question will then arise, "Where is the wood to protect them in their young state to come from?" Turning to the railways which are now being formed in every county in England, another and greater question arises as to the supply of wood which will be required in *their* construction. Go up, I am told, to the Lebanons of our island—those immense forests in the north of Scotland—and there hew down as many trees as will be required. From those, however, I find we must expect but a limited supply. Like the famous Mount of old, they are already overrun with the axe, and a continuance of the present rate of demand for a few years more will reduce the trees upon them to a mere remnant. It is not the original numbers required for sleepers which will effect this change, but it is the incessant demand, *ad infinitum*, for timber to replace that which is already laid down, or may be for the future laid down in additional lines. Look at it how we may, the state of our country at the present crisis proves that our immense and almost measureless tracts of what is generally called waste land were not created to be a scene merely of unproductive solitude. The rains with which they are refreshed, and the fostering sunshine that rests upon them, might have taught us that Providence had designed them to contribute in some way or other to the wants of man; and though Nature has been unable to lead us to comprehend her lesson, so simply brought before us, necessity has at length compelled us to look to those districts where only a sufficient quantity of timber can be raised to meet our increasing wants. Now, then, is the time to plant: wherever there is a waste piece of ground, moor, or mountain, let it be forthwith invested with trees, for every year, for many years to come, will unquestionably bring with it an additional demand for timber. Thus far on the necessity of planting. Allow me next to bring under notice the sort of tree I would recommend to be planted, which is the chief aim of this Address. That tree is the TRUE HIGHLAND PINE, for introducing which I had the honour, along with my brother, of receiving the Highland Society's prize. It is admirably fitted, in every respect, to take possession of all the uplands throughout England. It will grow freely on all soils suitable for the common Pine; its wood is very durable; and for railway sleepers it is unrivalled. Brindley, the celebrated engineer, considered its durability equal to that of the Oak; and Dr. Smith states, in the *Transactions of the Highland Society of Scotland*, that he has seen some of it taken down after it had been 300 years in the roof of an old castle, as fresh and full of resin, as newly imported timber from Memel, and that it was actually worked up into new furniture. "Such," says Loudon, "is the durability of this wood, that while the bog timber of the Birch is often found reduced to a pulp, and the Oak cracks into splinters as it dries, the heart of this Pine remains fresh, embalmed in its own turpentine."

MY LORDS, LADIES, AND GENTLEMEN,—Allow me to add a word or two on the merits of this tree as a landscape ornament. In this respect it rivals, if not excels, the Cedar of Lebanon. It has, at any rate, a much better ramification than the Cedar; for, as Sir Walter Scott observes, it assumes in a great measure the bold and contorted figure of the Oak. In illustrating the Seats of Norfolk (and the remark is applicable to all England), it frequently occurred to me that advantage had not been taken of prominent situations by investing them with grand evergreen trees; for so soon as November comes, our parks lose almost all that weight of grandeur for which they are so celebrated in summer-time. Their solemnity ceases with the fall of the leaf; but were they ornamented with this Pine, its broad umbrageous canopy remaining green during winter, the change consequent upon the approach of winter would be much less observed, and our country residences would at all times be surrounded with the dignified accompaniments so consistent with their character.

The importance of this subject will, I doubt not, be accepted as an apology for my thus venturing to express my opinions so plainly on matters of English practice. My suggestion as to the improvement of park and pleasure-ground scenery by introducing the Pine in question is offered with the greatest deference, being fully persuaded that in matters of this description England has been always distinguished for its refined taste. I am ready to dispose of the Highland Pines at the following prices:—

Single Plants, strong and well rooted	6*d.* each.
Strong Plants, 18 to 20 inches high	1*s.* per 100.
Strong Plants, 15 to 18 inches	30*s.* p. 1000.
Smaller-sized Plants for exposed situations	10*s.* to 20*s.* p. 1000.

I have the honour to be, My Lords, Ladies, and Gentlemen,
Your most humble Servant,
JAMES GRIGOR, NURSERYMAN, Norwich.

TO THE CULTIVATORS OF ROSES.

R. B. BIRCHAM, Hedenham Rosery, Bungay, Suffolk, begs to offer the following choice PERPETUAL ROSES. Good dwarf plants, own roots, suitable for pot culture or transplanting into the open borders.

Aricie	2*s.*	6*d.*	
Aubernon	2	6	
Augustin Mouchelet	2	6	
Clementine Berlage	2	6	
,, Duval	1	6	
Dr. Marx	2	6	
Duc d'Aumale	2	6	
Duchesse de Nemours	3	0	
Duchess of Sutherland	2	6	
Earl Talbot	2	6	
Fulgorie	1	6	
Jules Depont	2	6	
La Reine (strong plants)	7	6	
Lady Alice Peel	5	0	
Lady Fordwich	1	6	
Lane	2	6	
Madame Laffay	2	0	
Madame Cosna	2	6	
Madame Elliot	2	6	
Reine de Galles	2	6	
Rubens Rosea	2	6	
Reine de la Guillotiere	2	6	
Rivers (Laffay's)	2	6	
William Jesse	2	6	

BOURBON.

Acidalie	1*s.*	6*d.*	
Alfred	2	6	
Anne Boleze	2	6	
Armosa	1	6	
Caresse	2	6

Cloth of Gold (Noisette), strong plants, 7*s.* 6*d.*

Choice Roses selected from various classes:—Dwarf Standards, 12*s.* per dozen; do., superior kinds, 18*s.*; Standards, 18*s.* per dozen; do., most superior, 24*s.*

A descriptive Catalogue sent on application. Plants guilty to compensate for distant carriage.—Bungay, Nov. 30.

LANDSCAPE GARDENING AND GARDEN ARCHITECTURE.

MR. GLENDINNING, since his residence near the Metropolis, has had the honour to be consulted by a number of Noblemen and Gentlemen in the improvement of their Parks and Gardens, and in the construction and heating of Horticultural Buildings in the most ECONOMICAL as well as effectual manner. He has now made such arrangements as will enable him to devote his particular attention to these important subjects; and Noblemen and Gentlemen desirous of consulting him, are respectfully requested to address him at Chiswick Nursery, near London.

WANTED, 500 YEWS, 6 inches high; 250 BUCKTHORNS, 1 foot high; 50 Small DECIDUOUS CYPRESS. Prices to be sent to Mr. MATTHEWS, 5, Upper Wellington-street, Covent Garden, London.

The Gardeners' Chronicle.

SATURDAY, NOVEMBER 30, 1844.

MEETINGS FOR THE TWO FOLLOWING WEEKS.

MONDAY,	Dec. 2.	Entomological	8 P.M.
TUESDAY,	Dec. 3	Horticultural	2 P.M.
		Linnean	8 P.M.
WEDNESDAY	Dec. 4	Society of Arts	8 P.M.
FRIDAY,	Dec. 6	Botanical	8 P.M.
WEDNESDAY	Dec. 11	Microscopical	8 P.M.
SATURDAY,	Dec. 14	Royal Botanic	4 P.M.

WE proceed to redeem our promise of offering remarks upon the EXPERIMENTS made by our correspondents with POTATOES during the past season; and we commence with one of singular interest and importance by Mr. GREY, of Dilston, the full particulars of which will be found in another column.

It is well known that whatever care may be bestowed in taking up a Potato crop in the autumn, some tubers will remain in the ground; and it has been observed that the plants from such tubers are extremely vigorous when they make their appearance in the succeeding spring. Potato-growers are also aware of the existence of a prolific variety called the Onion Potato, which is always allowed to remain in the ground during winter. These, or some such facts, have led to the suspicion that it would be better to set Potatoes in the autumn than in the spring, and that this sort of plant is hardier than is generally supposed.

Mr. Grey, of Dilston, in the experiment now published, has put this question to the test; and, considering the care and skill with which the trial was made, we must regard it as conclusive under exactly the same circumstances. It will be seen that autumn-planted crops gave a return of 111 loads per acre, while the spring-planted produced but 86 loads, although, with the exception of the season of planting, all other circumstances were equal.

The circumstances under which so enormous a difference was obtained, without the expenditure of one shilling more in the cost, are deserving most careful investigation. It appears that the main features in Mr. Grey's operation were—1. That the Potatoes were replanted as soon as they were taken up; 2. That a moderate quantity of but slightly-fermented dung was employed; and, 3. That the sets were well covered in by deep ploughing. Of these the two last are, we imagine, the most important; and they are probably indispensable to success.

Whether or not the Potato is reset as soon as taken up, or at a later period in the autumn, is perhaps unimportant; and therefore we should be inclined to attach little weight to the supposed difficulty of getting land ready so early as to take an autumn crop of Potatoes directly after harvest. If they cannot be planted, like Mr. Grey's, by the 20th October, they might, we conceive, be in the ground without risk a month or five weeks later, in well-drained land, without any difference in the result. Our reason for entertaining this opinion is, that the Potato undergoes no change during the autumn or winter—it is only when the spring returns that mischief is done to the Potato seed by sprouting and heating; and it can hardly make a difference in the result whether the Potatoes to be planted are buried in drills in the soil of a field, or in heaps of earth in any other place. We would, therefore, advise the experiment to be tried even now, if the weather remains mild enough, by those who have land in proper order, provided it is light and thoroughly drained. It would, however, be better now to plant whole Potatoes rather than sets.

The two last precautions adopted by Mr. Grey may be considered together. Potatoes cannot bear frost: the objection to autumn planting is the supposed difficulty of preserving them from it with certainty. By a slight addition of loose dung, and burying them to a sufficient depth, Mr. Grey was able to keep off the frost of 1843-4; and therefore he succeeded. But it remains to be determined whether the same precautions will be sufficient in another winter. We do not know what was the lowest degree of temperature near Newcastle last winter, but we find that near London the thermometer never sunk lower than 14°, and that frost did not penetrate the ground there deeper than 2 or 3 inches. From so slight an amount of cold the means employed by Mr. Grey would be amply sufficient to guard the Potatoes. But would they be equally effectual in harder winters?

The difficulty of answering this question with confidence arises out of the insufficiency of our information concerning the temperature of the soil. Observations on the temperature of the air are endless; on that of the earth very few. Indeed, we cannot lay our hands upon any in which confidence can be placed, except those of Mr. Ferguson, of Raith, and such as have been recorded in the Garden of the Horticultural Society. It appears from the former observations, that at one foot below the surface the thermometer stood as follows:—1816, Jan., 33°, Feb., 33°.7, Dec., 35°.7; 1817, Jan., 35°.6, Feb., 37°, Dec., 35°.9. (See "Theory of Horticulture," p. 95). It is therefore to be inferred that a covering of soil to the depth of a foot would have proved sufficient in all these months. Moreover, loose soil conducts heat worse than hard soil, and the loss of heat would be still further diminished by long litter used with it, so that Mr. Grey's method would probably afford ample protection in such seasons as that of 1816 and 1817. We should, indeed, be inclined to think that it would afford protection in any English winter; for at a foot below the surface, in solid ground, experience shows that the temperature in winter is about a degree or a degree and a half above the *mean* temperature of the atmosphere. It is true that, according to the testimony of various persons, a much greater degree of cold is experienced in the soil. It was, for instance, stated that during the hard frost of 1837-8, the ground was frozen to the depth of 28 inches at Claremont, and at Liverpool to the depth of 18 inches; but it is to be remarked that in the former of these places the thermometer in the air is said to have fallen to 14° *below* zero, while in the latter it was not less than 9° *above* zero. There is, however, great reason to suppose, either that there was some error in those observations, or that the state of the earth was modified by unexplained local causes. For in the very carefully conducted experiments in the Garden of the Horticultural Society, the solid ground at one foot below the surface was never actually frozen (although the thermometer fell to 4½° *below* zero), the lowest range of a thermometer buried one foot below the surface having been 33°; and it was found by digging, that the frost had only penetrated the loose soil of the Kitchen Garden 9 inches; a hard loam footpath 10 inches; the soil of a mossy lawn 5 inches.

What experience we have then, leads us inevitably to the conclusion that autumn planting, with the precautions taken by Mr. Grey, will not only succeed in mild winters, but probably also in our hardest. And this conjecture is rendered the more plausible by the well known fact, that plants, even when frozen, are but little injured if they thaw slowly, and in the dark, which is precisely what must happen to the buried Potato. We would, therefore, have Potato-growers bestir themselves and attend to this matter; for we presume they can have no objection to change their 15*s.* for a guinea, which was about what happened in Mr. Grey's very important experiment.

AMONG the smaller class of contrivances which the fondness for house-gardening has called into existence, nothing is better in its way than Mr. BECK'S SLATE POT, made by jointing together small slabs of slate into the capacity of a common garden-pot. To be sure, they are at first somewhat expensive, but, like many other expensive things, they are really much cheaper than what costs less money; for they cannot be worn out, and can scarcely be broken; besides which, they are much better suited for sitting-rooms than common garden-pots, whose porous material renders it difficult to keep them moist without being wet. Some of the finest Roses and Pelargoniums that appeared at the London Shows last year were grown in this kind of vessel, and every one who saw them must admit that they were unsurpassed. Slate pots possess, moreover, the convenience of being square, so that they can be easily packed into any given space, and of being heavy, which prevents their being easily upset.

In short, they are a prodigious improvement upon the garden-pot, both as regards appearance and utility, and we heartily recommend them to the favourable consideration of the public, who will not think the worse of them when they know that their fabrication gives winter employment to some very worthy and deserving workmen.

To this we would add a word of commendation in favour of MR. HUNT'S NEW HYACINTH POT, made in ornamented China, and in the form of the common Hyacinth-glass. It has a neat contrivance for fixing the wires required to steady the flowering spike and leaves of the Hyacinth, and presents the advantage of keeping the young roots of this bulb in the dark. To this we may add, that they are better-looking than the Hyacinth-glasses in common use.

ON PRUNING FOREST-TREES.

WITHOUT entering into the controversy between Dr. Thackeray and Mr. Billington, on their different systems of pruning forest-trees, I beg to give what, according to my limited experience, I conceive to be the best system of pruning trees which are designed for timber.

The object aimed at is to produce the greatest quantity of timber, of the best quality, in the shortest time. If the object were simply to produce the greatest quantity, without having regard to its quality, there is no doubt that this would be best accomplished by judicious thinning, and in other respects leaving the trees entirely to nature. For it is generally agreed that the office of the leaves of a tree is to elaborate the crude sap which rises from the root, and form it into *cambium*, or proper juices, which descend and form every year a layer of alburnum or soft wood between the bark and the wood of the previous year, down to the root, which alburnum hardens into timber; and the longer the tree stands the harder it becomes, from the pressure of the successive annual layers. This being the case, it is easy to understand that a tree loses an organ of nutrition in every leaf that it is deprived of. But it is required that the timber should be of good quality, as well as great in quantity; and this treatment would not answer for that purpose; because the best timber is produced in the bole, and by leaving a tree to Nature, the branches, where they had room to grow, would increase at the expense of the bole, which would then most probably become forked at a short distance from the ground. The object of pruning, therefore, is to obtain a tall, straight, and thick bole in as short a time as possible.

Now, if the growth of trees be carried on in accordance with the principles above alluded to, and the leaves perform the important functions attributed to them, I conceive that in order to obtain the desired end, two objects ought chiefly to be kept in view, viz., to increase, as much as a tree is capable, the amount of its foliage, and to decrease, as much as possible, the amount of wood in the side-branches. If both these objects could be accomplished at the same time, and in the same tree, the foliage having little or no wood in the side-branches to support, the timber in the bole would rapidly increase. But since this is impossible, as these two objects are incompatible with each other, and cannot be both fully attained, the best mode of pruning is that which can most nearly unite the accomplishment of both these objects, and make the one yield to the other in the proper proportion.

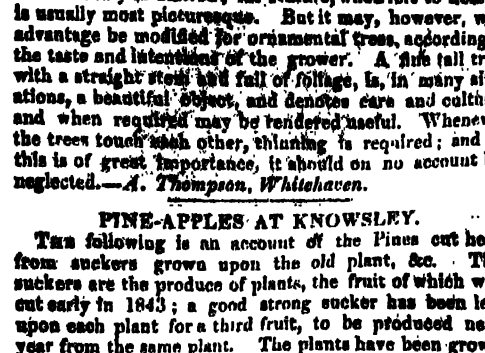
The following method is the best with which I am acquainted for effecting this; and, so far as I can judge from the little experience of it that I have had, I can confidently recommend it as likely to prove successful, if properly followed up.

Commence pruning when the trees are young; and, beginning at the top of a tree, cut off all the leaders but the strongest and best ones, at the second or third bud from their base; then cut off the first side-shoots below these, at the fourth or fifth bud from the main stem, the next at the sixth and seventh, and so on, downwards, in regular gradation to the bottom; so that the tree may assume a conical shape, each side-branch projecting a little further from the main stem than the one immediately above it. I do not mean that these directions should in every case be followed exactly; I merely give the principle, as nearly as I can. By this mode the lateral branches of the tree, instead of becoming large and projecting far from the stem, with perhaps only a few leaves at their extremities, will be kept of a moderate length; and small branches bearing leaves will be greatly multiplied, so that the tree will be well clothed with foliage nearly from the top to the ground, and a quick upright growth will be produced. This pruning should be repeated every year, or oftener, if required; and it may be done at any season of the year, as the branches to be cut off will always be small, and therefore small wounds will be made; and time would be lost by delay, although the best season is the early part of summer, soon after the trees have completed the growth of their spring-shoots.

As the tree rises, the lower branches should be suffered gradually to extend, which they will be able to do, if the branches above them are not permitted to overhang their extremities, and the conical shape will thus be preserved, and its appearance will be somewhat like that of the figure. This system of pruning is intended for deciduous trees; but it may be partially applied to evergreens with advantage. It is well adapted to exposed situations, as the leading shoots grow stronger and are better able to bear the exposure, and the closeness of the foliage and small branches assists in protecting the stem from the chilling and drying influences of wind and weather. The tree should receive no other kind of pruning than the above, if it were not required that the timber should, as far as possible, be uninjured by knots. But on this consideration only it will be necessary, when the tree attains the height of about 12 or 15 feet, to commence pruning away gradually the lower branches, by cutting off one tier only every year, smooth and close to the stem, leaving no snags, but taking care not to carry this process too far—not denuding the stem for more than about half the height of the tree. When trees are intended for shelter or a screen, the lower branches ought not, of course, to

be cut off. This method of pruning is not adapted to trees intended for ornament, particularly single trees, where beauty is desired; for Nature, when left to herself, is usually most picturesque. But it may, however, with advantage be modified for ornamental trees, according to the taste and intention of the grower. A fine tall tree, with a straight stem and full of foliage, is, in many situations, a beautiful object, and denotes care and culture, and when required may be rendered useful. Whenever the trees touch each other, thinning is required; and as this is of great importance, it should on no account be neglected.—*A. Thompson, Whitehaven.*

PINE-APPLES AT KNOWSLEY.



The following is an account of the Pines cut here from suckers grown upon the old plant, &c. The suckers are the produce of plants, the fruit of which was cut early in 1843; a good strong sucker has been left upon each plant for a third fruit, to be produced next year from the same plant. The plants have been grown in pots, plunged in a common pit filled with leaves and tan. The twins are produced by allowing two suckers to remain upon the old plant to fruit in one pot:—

1844 When cut.	What kind.	Weight. lbs.	oz.	How Grown.	Remarks.
August 23d	Montserrat	4	10	Sucker.	All grown in pots, and plunged in tan and leaves in a state of fermentation.

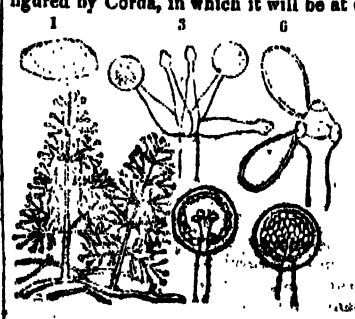
ENTOMOLOGY.

Diseases of the Larch.—This handsome tree, as well as the other Coniferæ, is subject to the attacks of various insects; and, amongst others, to a species of Coccus, I believe; but its economy requires to be more rigidly investigated before the genus can be accurately determined. From the number of communications I received in the early part of the year regarding these insects, I am induced to enter upon their history, imperfect as my materials may be; and I trust that it will lead to the study of these curious animals, and to a more perfect knowledge of their economy the ensuing spring, when I doubt not they will make their appearance, as I never searched for them unsuccessfully.

Towards the end of last April, the Larch-trees, as they burst into leaf, were infested with a disease somewhat resembling the American blight, occasioned by a little black soft animal (fig. 7a—the underside highly magnified), the apex being more or less covered with a short white cottony substance. These creatures, which are exceedingly like the various species of Coccus, or rather of Aspidiotus, when the scale is removed from them, are somewhat orbicular or oval, and less larger than a pin's head; they have six very small legs, and a short stout proboscis, from which proceeds a long flexible setiform tube of exceeding fineness, which was inserted into the scales of the bud; the apex of the abdomen was slightly conical, and exhibited several segments, and others were less visible in the region of the trunk; they were either seated upon the buds where the leaves are produced, or behind them; and close to this animal were clusters of minute eggs (fig. 2), amounting to 30 or 40 in each (fig. 3, several magnified); they are attached by a long, excessively fine thread, proceeding from one end (fig. 4), and are of a yellowish colour; but often completely powdered over with a fine lilac bloom. At the same time, scattered over the leaves were minute black specks, scarcely visible to the naked eye (fig. 5), but which, under a lens, proved to be black insects, which I suspected at the time were bred from the eggs; and this opinion was strengthened by the fact, that as their numbers increased, the clusters of eggs became emptied of their contents. They moved about freely at first, but when they had fixed upon a leaf, their fine rostrum was at once inserted into it, and from that time they appeared to rest in a dormant state; some were not unfrequently lying on their backs—others, small as they were, had cast their skins, which were either adhering to their tails, or stuck to the leaf at a short distance off. Under a microscope, these black atoms exhibit a very different appearance to their female parent, if such the Coccus be; they are elliptical, and have large black heads, with two short stout antennæ; the two basal joints are large, the remainder tapering; the thoracic segments are distinctly visible, and furnished with six short legs; there are four rows of minute tubercles down the back, and the lateral margins are likewise tuberculated (fig. 6).

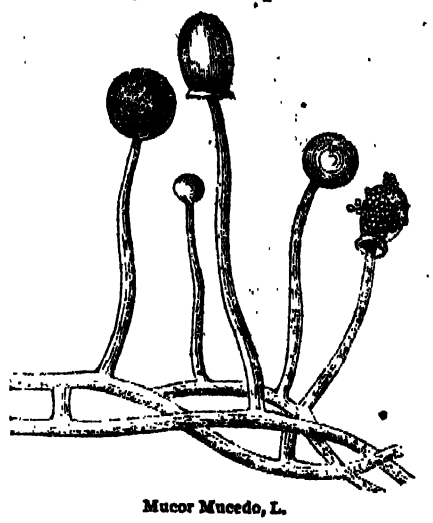


In the beginning of June I observed these young animals had spread themselves over the leaves of the Larch-trees, and were beginning to be clothed with a cottony substance. Here my observations were interrupted, for I returned to London, and the twigs I took with me did not remain fresh long enough to throw any more light upon their economy.

These animals seem to form a connecting link between the Scale insects (Coccus and Aspidiotus), and the genus Eriosoma, which unites them to the Aphides or Plant-lice. What I take to be the female agrees very well in structure with the Cocci; but it is destitute of a scale, and the eggs are deposited, not beneath the mother, being too large to occupy such a position, but on one side of her, and most curiously attached by a pedicel to each; and here another question arises: Are these fleshy females the authors or the produce of the adjacent eggs? for it is possible the female eggs might have been laid the previous autumn, and that the inmates had hatched and assumed their present form before the minute black ones made their appearance; but this is merely a conjecture. The young, if I be correct, are not like the generality of Cocci, having no setiform tails, still they are not very different in form from the Coccus (Trechocorys) Adonidum, and it is possible they may be the Adelges laricis of Vallot, but I think not. Most of these doubts would be set at rest by detecting the adult males, which are probably winged.

With regard to the best means of freeing the Larch-trees from these and similar insects, I fear it will be impossible to suggest any that could be applied until the foliage has fallen; for whilst the leaves remain, the same difficulties would present themselves as in the bristly Pines, where scrubbing and painting the branches cannot be resorted to, as in fruit-trees, &c. Such, however, is not the case with the Larch after it is deprived of its foliage, when any application may be tried, should it be found expedient; and perhaps none is more simple or better than brushing on a good coating of lime or clay, or both mixed, which would render the trees less unsightly. Such a process, if persevered in, would certainly destroy the delicate eggs we have described, wherever the brush reached them, and the coating, when it dried, would prevent any of the young broods from piercing the buds; it would, however, be a tiresome mode if well performed, and not feasible in an extensive plantation. —*Ruricola.*

DISEASES OF PLANTS.—No. VII.



It was remarked in a former Number, that there are two great divisions of Fungi, distinguished by the mode in which the reproductive organs are developed. In the one they are external; in the other contained in little sacs. There is, however, a small group, which though at first sight related to the second class, inasmuch as the fructification is, according to the letter, internal, are really more nearly related to the former. The fact is, that the reproductive bodies are truly spores, though produced within a sac, the vesicle which surrounds them being of the nature of a veil, and indeed a mere continuation of the outer membrane of the matrix. The structure is beautifully illustrated by a very pretty species of mould figured by Corda, in which it will be at once seen that so soon as the vesicle is removed, there is nothing to distinguish it from the sporiferous moulds; and a strong proof of this is afforded by the fact that in more than one instance the early and mature plant have been assigned to different genera, and where this has not been the case, much doubt has existed as to the real structure of the fruit, because the outer vesicle is extremely fugacious, and the spores remain for a long time attached to the internal vesicle.

Acrostalagmus cinnabarinus. 1. A patch, the natural size. 2. Plants very highly magnified. 3. A portion of the fructification still more magnified. 4, 5. Spores plunged in gelatinous heads. 6. A point of a branch with two spores remaining upon it.

Another curious point is, that as in the Mushrooms, the same spicule has been observed to produce a succession of spores, so in the plant now figured, one spore as soon as it is ripe falls off, and makes room for another, the whole being retained within the globular sac till its rupture.

To this group belong a portion of the Fungi known under the name of moulds. That which occurs so frequently on bread affords a familiar example. They are produced with extreme rapidity, and when they establish themselves on a tender juicy matrix, are very destructive. The most common, perhaps, is Mucor mucedo, which abounds on fruit and substances containing fecula or sugar. The spores are at first internal; but the outer vesicle soon bursts, leaving a little frill at the base, and after the spores are washed off, a clavate columella is seen, on which they were at first generated.

Mucor Mucedo, L.

Considered as the causes of disease, the Mucors and allied genera are destructive to fruits, or very succulent parts only, as they require abundant nutriment. They may, indeed, sometimes be seen forming juicy masses upon the wood of shrubs which have been cut off after a hard winter; and though in such cases new shoots are not sent up so vigorously as usual, this may arise not from any evil influence of the mould, but from the loss of the sap which should have nourished the shoots. It is, however, to fruits principally that they are injurious, and any slight wound from insects or cracks arising from a too copious supply of water after a few dry days, affords a matrix of which they soon avail themselves. Mr. Hassall has made some interesting observations on the decay of fruit, in consequence of the growth of moulds, but attention will be pointed to these when we come to that group to which more especially they belong. The species now under consideration seldom appears except where there has been some previous injury exposing the soft cellular substance, though they spread like wildfire as soon as they are once established, as may often be seen in autumn in large Gourds and Cucumbers, which are subject to the attack of a species so minute, that the heads are scarcely visible except under a lens. They afford very pretty objects for a microscope of small magnifying power; indeed, few are more beautiful than the branched mould, which so often destroys woodland Mushrooms; and the purple-fruited species, which sometimes grows on Pears, is scarcely less splendid than a plume studded with amethysts.—*M. J. B.*

Home Correspondence.

Botanical Lecture at Shoreditch Church.—This lecture, of which inquiry is made by your correspondent "T.G.H.," was established in consequence of a fund being left for the purpose by Thomas Fairchild, a distinguished market-gardener of the last century. He was one of the few cultivators of the soil, living during his period, that combined science with practice. He made experiments on the circulation of the sap, which appeared in the "Philosophical Transactions" for 1724, and was the author of the "City Gardener," published in 1722, as well as of various communications to be found in the works of Dr. Bradley. He died in 1729, at Hoxton, where he cultivated a vineyard, almost the latest on record, and bequeathed money to trustees for insuring the delivery of a lecture on Whit-Tuesday annually, in the church of St. Leonard's, Shoreditch. The subject must be either "The wonderful Works of God in the Creation;" or "The Certainty of the Resurrection of the Dead proved by the certain changes of the animal and vegetable parts of the Creation." It is well known as the Fairchild Lecture, but whether it continues to be delivered, as it undoubtedly ought, I cannot say.—*G. W. Johnson.*

The Strawberry.—The following is the result of a few observations on this plant, in the different stages of its growth, from which I hope to be able to prove that an easily-understood method of cultivation may be successfully adopted. If you examine a Strawberry-plant, or runner, in October, it will be found to have produced several straight and succulent roots springing from a bulb-like hard but succulent stem, and several leaves, more or less in number in proportion to the vigour of the plant. In the axil of each of these leaves a bud is formed, and it is the general opinion of gardeners that the fruit is produced directly from these buds. This is, I think, an error; for I have always found that the blossoms are produced from the crown of the offset or runner, and I have seldom found any strong, healthy blooms on these crowns after the first year of bearing. The runner is generally considered to be a perfect plant, that will, if placed under favourable circumstances, very

seldom fail to produce fruit in perfection the following year. In the months of March and April following, if the same plant is again examined, the buds that were observed in the axil of each leaf will be found to have produced a few leaves, and blossoms will be perceived at the crown of the runner; during the time that it is perfecting its fruit, the buds before mentioned will in one part be formed into runners whose sarmentum will have removed them to a distance, whilst the other part of them will be formed into offsets, which are closely attached to the parent stem. It is of importance to observe, that at the same time the offsets are producing leaves, that roots are also formed which strike into the soil, and those that are nearest the surface will be observed to produce longer roots than those that are a little elevated above the soil, but they are distinctly visible in all. The crown of the original plant will, during this time, be considerably elongated, and the roots proceeding from it will be found to have become ligneous and fibrous, and of a deep brown colour. From this, the original crown, as before stated, I have reason to believe no fruit worth notice is afterwards produced. Having now brought the examination down to September or October in the year following that in which the first runner was examined, we have next to look into the state of the plant in the following year. The runners, having taken root at a distance, will require no particular notice, as they will be in the same state that the single runner was at the same period in the preceding year, when we commenced our observations; but we shall find the offsets under very different circumstances. Each offset has become a perfect plant, with leaves and roots, and is qualified to produce fruit; which it would no doubt do, were it not prevented by want of space in which it might develope itself. I have counted 36 offsets upon one Strawberry-plant, at this period of its growth; now, it cannot fail to be observed that each of these offsets and runners will, after this time, annually produce its runners and offsets, until the bed becomes a dense mass of unproductive plants from the want of space, and from being deprived of sun and air, so necessary for forming and elaborating the sap for the production of fruit.—*W. Darke*, 335, *Coventry-road, Birmingham.*

Bees.—In consequence of reading Mr. Pettigrew's Articles on Bees. I was induced to make a large hive, 20 inches in diameter and 13 inches in depth, on the 13th of May last. I placed a good first swarm in this hive, and on the 26th of the same month I put a second swarm into one of Mr. Golding's hives. Both swarms worked well until September, when I removed the bees from both hives and took the honey. The large hive, from which I was led to expect so much, yielded me 10 lbs. of honey, and the small one, from which I expected but little, gave me 12 lbs. What might have been the result had I waited until another season I cannot tell; but I am disposed to think that Mr. Pettigrew's hives are much too large for a locality like this, where the honey-gathering season is of short duration. So much time is necessarily spent in furnishing these hives with combs, that but little is left for storing them with honey.—*Thomas Buckland, Reigate.*

Covering for Frames.—About a month or two ago I prepared the coverings of some frames with the varnish described by "Devoniensis" at p. 301, 1843, and again at p. 392, 1844. I gave them two coats, allowing the first coat to get quite dry before the second was put on—(it did not dry so quickly as I anticipated); after the coverings were finished they were very transparent and almost colourless, and they remained so until a few days ago, when I perceived that they had become quite yellow; they were not in use, but were hung up in a dry airy place; others which were varnished a few days before, and which are in use, remain as transparent and colourless as when first done. Can you tell me what is the probable cause of this change, and whether there is any way of restoring them to their original state?—*Y. Y. Y.* [Perhaps "Devoniensis" will be so good as answer this.]

Potter's Guano.—I have this year tried Potter's guano, which I have found to be quite equal to the character which it receives. I used it for annuals, at the rate of 6 oz. to the square yard; the flowers were itself larger, and remained longer in beauty than any I have seen this season. The annuals were sown on a border where Gooseberry trees had grown for several years; it had not had any manure given it for two years. I have also used Potter's guano for Onions, at the same rate, and the result was quite equal to that from old horse manure, but not better. For flowers I consider it far superior to any manure I have tried.—*C. J. Perry, Handsworth.*

Planting Fruit-trees.—This spring I limed three newly-planted standard Apple-trees, having previously cut away, close in, two-thirds of the shoots, applying Forsyth's plaster to the wounds in a careless way. The dry spring has much damaged new-planted trees; these three Apple-trees have, however, made splendid shoots. The stems have grown very much, and the bark the most smooth, clean, and shining that can be conceived. They had one washing only. The other trees similarly treated but not limed are very inferior in appearance, although standing with them. I applied turpentine to one which was covered with the white blight, brought from the nursery. It killed the blight where it went, but burned the tree, or something like it. Would a weak solution answer?—*M. U.* [No. Spirits of tar are the best remedy for American blight.]

Jets d'Eau.—There are few things in gardens that give more pleasure to the eye than a diversity in the play of water, more especially on a hot sultry day, when it contributes to cool the air, as well as enliven the prospect. Whatever be the direction of the jet, the discharge of water is always the same, provided that the ajutage and the altitude of the reservoir be the same. This is a necessary consequence of the equal pressure of fluids in all directions. Water spouting from a small ajutage has sufficient velocity to carry it to the same height as the water in the reservoir, but it never attains entirely this height, being prevented by various concurring causes:—1st, Friction in the tubes; 2d, Friction against the circumference of the aperture; 3d, The resistance of the air; its weight obstructs the rising column. Thus the Emperor Fountain, lately erected at Chatsworth, with a fall of 381 feet, only raises a jet 267 feet in height. The above causes account for the loss; as all are aware if a pipe were laid to a corresponding height, the column of water would then rise to the height of the place from whence it was supplied. In order to make large jets rise higher than small ones, the conduit-pipe must be large enough to furnish a sufficient quantity of water to supply them. History informs us that the ancients were far before us in this delightful ornament. Greek cities were adorned by them; in Corinth there were several; in Rome, Frontenus was employed in erecting fountains; Pompeii had many, some of which remain to this day. The Fountain of Trevi, and the Pauline Fountain at San Pietro, in Montono, are immense piles of architecture. Italy has employed all her talent in designs for this purpose, and Paris has many—we may call it the City of Fountains; but London, although well supplied with water, is almost destitute of this ornament. However, I am glad to perceive a growing taste for them in the nobility and gentry, for decorating their flower-gardens, &c., as well as in the Government, for placing them in the public parts of the metropolis. I need scarcely remark that it would add much to the cleanliness of this vast city if one was erected at the corner of every street, where there is space. I hail the present day as one of great improvement in this particular. Mr. Roe, in the Strand, has turned his attention to the subject, and I trust he will meet with encouragement. He has also improved the Hydraulic Ram, by which he can raise water from a fall of 10 feet to the height of 300 feet, without labour. The following are a few of the largest fountains in Europe:—

The Emperor, at Chatsworth, height of jet	267 feet
Wilhemmshe Fountain in Hesse Cassel	190
Fountain St. Cloud	180
Peterhoff, Russia	120
The Old Chatsworth	94
Versailles	90

Jointing Earthenware Pipes.—I see by the *Chronicle*, that many of your correspondents are inquiring for a mode of cementing earthen pipes for conducting hot water. I have never used any such myself, but if some of them would try the following, if it has not already been tried, probably it might answer their purpose; in which case I trust they will make known the result to the public. I have seen it used by potters, where pots have cracked in the kiln, and afterwards have found them to be quite sound and useful. Take one pint of sweet milk, nearly two pints of buttermilk, mix the milks, and put them on a slow fire till they turn into curds; then strain them and save the curds. Previously get some good roche lime, pound it fine, and sift it through a fine sieve. Mix the lime with the curd well, until it is tough, and then lute the joints well with it; the pipes should be dry when the cement is applied. It will be sufficiently hard in a few hours, and will not, I think, be affected by hot water. More cement than can be used in half-an-hour ought not to be mixed at a time, as it will get so hard as to be unfit for use. It may be coloured, if necessary, with a little Spanish brown.—*J. Lyons.*

Fuchsias.—Observing in a late *Chronicle* the statement of "A. C." respecting the keeping of strong shoots of Fuchsias among powdered charcoal through the winter, has induced me to mention the following plan, which I tried last year with success. On the 20th of Nov., when I cut down the Fuchsias in the shrubberies, I selected the strongest shoots, and making them into cuttings, planted them into the open border, in rows about 1 foot apart. The plants stood about 3 inches apart in the row, and were covered over with fresh leaves to keep out the frost. The leaves were removed in the month of March; and at that time the buds on the Fuchsias were breaking. I took up one or two of the plants, which I found had made fibres about 2 inches in length. I put in 900 cuttings in this same way, and out of the 900 about 800 struck roots and flowered well through the summer. Another plan is to tie them up into bunches, and placing them below a Laurel bush, for the purpose of keeping them from frost, to make them into cuttings in spring, and plant them then; but they flower much earlier when put in in November. About the place where I reside, there are some thousands of Fuchsias in the shrubberies. When I cut them down last year, I dug into the ground some of the branches, which struck root next spring, and set up young shoots. They grow here as freely as Willows.—*W. C., Forfarshire.*

Fish-ponds.—In answer to "E. W. M." (p. 784,) respecting these, I beg to quote the opinion of Salter—a good angler, and a person who seems to have studied the nature of fishes. He says, "It is improper to plant trees close to a fish-pond, because when the leaves fall they rot, and make the water unclean, and consequently injurious to the fish." These remarks apply more particularly to stews or small ponds; on the other hand, if the ponds are large, and have a good stream running through them, the trees, I conceive, would be beneficial, on account of insects dropping from them into the water, and serving as food for the fish.—*A Reader.*

Morphology.—The recommendation of "A Gardeners' Wife" to be careful, is one which will apply to every person, at all times, and under all circumstances;—for instance, too much care and study can hardly be bestowed, before forming an opinion which is adverse to the plain truths of Morphology. It is true that opposition, like the fiery furnace, will serve to refine it, and separate its dross; but it is not so apparent that those who condemn, without giving it a candid and unprejudiced examination, are altogether blameless. When this lady can spare time from her domestic engagements, to give this subject such a consideration, I have no doubt that her opposition to it will cease; and, intimately connected as she is with the profession of gardening, perhaps no study, apart from her own peculiar province, would present an equally engaging field for the exercise of her mental faculties. With respect to the Achimenes, she will then, perhaps, distinguish between expressions which respectively relate to proximate and ultimate results. I may mention, that in as far as I have meddled with this subject, I have sought rather to excite inquiry, than to make converts; and I am happy to find that this object has been realised.—*T. Moore.*

The Golden Pippin.—From several statements in the *Chronicle*, it would appear that an opinion generally prevails, that the Golden Pippin cannot now be successfully grown in this country. This arose, I believe, from a speculative opinion of the celebrated Mr. Knight, that this variety was in the last stage of decay. It has likewise been stated that "repeated attempts have not been wanting by planters to substitute these old fruits as orchard-trees again, but all have hitherto proved unsuccessful." I have known the Golden Pippin for these 40 years, and can safely aver that I have seen as few symptoms of decay about it, as about any other fine variety of the Apple whatever, when under proper treatment. The first Golden Pippins which I remember to have seen, were growing in Castlestead's garden, Dalkeith Park, then celebrated for its Golden Pippins and May Duke Cherries; the trees were trained against a stone wall which was 10 feet in height, and each tree covered a space of 30 feet in length. I can well remember the excellency of the fruit, but I have no recollection of any appearance of decay or canker about the trees; the soil was light, about 2 feet in depth, and the subsoil was a bed of gravel. About 22 years ago, an old Golden Pippin tree was blown down in the cottage garden, Nonsuch Park. I was directed by my employer to endeavour to obtain a few grafts of it, as he was desirous that so good an Apple should be preserved in the neighbourhood. I went and found that the stem was, indeed, in the last stage of decay; the top had already been cut into faggots, and was piled on the wood-stack, to the top of which I had to scramble. It was with great difficulty that a few grafts could be got, the young wood not being above half an inch in length; the scions were grafted on Crab stocks, and did well. The young trees were, after two years' growth, all given away, except one, which was planted in an open, unsheltered situation, in a very stiff soil; the subsoil was a strong clay. The ground had, however, previously been well drained, and has, ever since the tree was planted, been under a course of vegetable culture. How those trees which were given away may have succeeded I do not know, but the one which was retained has done exceedingly well. It is now a fine healthy spreading tree, with not the least symptom of canker about it, freely producing fruit, which is sound, and without blemish, of a rich yellow colour, with an abundance of spots or freckles of a russet tinge. That this is the true old or original Golden Pippin, I have little doubt; the tree from which the scions were taken, to judge from the size of the trunk, must at least have been 60 years of age, and I believe that the varieties of the Golden Pippin which we now possess have been obtained at a period subsequent to 80 years ago. Now, if a scion taken from a tree in the last stage of decay can, by grafting it upon a proper stock, and growing it in a suitable soil, be so invigorated that it increases yearly in size, health, and luxuriance, producing fine crops during the greater part of 22 years, may we not reasonably suppose, that under the same circumstances it may be continued to a much longer period, and that it may be renewed and continued indefinitely? I have seen the Downton Pippin in such a state of disease and canker that it was taken up and thrown away as worthless, and after lying about for a week, when replanted in a different soil and situation, it has become healthy, divested itself of all appearance of canker, and produced an abundance of fruit. The Old Nonpareil, too, I have known to be so much diseased, that out of a bushel of fruit scarcely six Apples have been worth preserving for dessert; but by trenching and renewing the soil, and properly pruning the tree, it has so far recovered, that latterly, and this year more particularly, it has borne as fine fruit as I have ever seen. Again, Apple trees, apparently in the last stage of decay, have by being grafted with sorts that are coarser feeders, having stronger organs of digestion, had their enfeebled stems overlaid with new and healthy wood, the bark has become clean, and all appearance of disease has vanished. But when we take into consideration the way in which orchards have generally been managed, the too frequent neglect of judicious pruning, and the consequent exhausting crops with no return of restorative nutriment to the soil, with occasional ungenial seasons, we need not wonder that Moss, Lichens, canker, and other debilitating causes soon render the Golden Pippin and other

fine varieties of the Apple unsuitable and unprofitable as orchard Apples. From these facts, may we not safely conclude, that the decay of the Golden Pippin in our orchards proceeds from other causes rather than from the variety being in the last stage of decay?—*James Falconer, Chesham.*

The Tom-tit.—If we succeeded, as "Dodman" (p. 766) wishes, in exterminating this, which he terms "a garden enemy," because it eats one or two choice Pears, which were not protected by a gauze bag, or some other simple contrivance, I fear we would be clearing a way for whole legions of real enemies, that would not only destroy a little fruit, but the tree itself! for, what bird works with more assiduity in the destruction of insects and larvæ of every description, and at all seasons, than the tom-tit? Only watch him peeping into every crevice, and multiply the thousands of destructive insects which he in one day destroys by the thousands they would have generated to ravage our gardens during the next season! and I think it will make "Dodman," or any other lover of birds and gardens, think twice before they killed one tom-tit; and lead him to preserve the tit-mouse as one of his best friends. Fond as I am of birds, I can say little in defence of the bullfinch, knowing something of his operations upon Plum, Cherry, and Gooseberry trees; but viewing, as I do, nature as a great chain in which the most minute creatures form a link, the destruction of one family would cause a confusion, all having a special duty to perform; and, I doubt not, that assigned to the bullfinch is a most important one. Should "Dodman" not consider the soul-enlivening music of the blackbird in our groves, sufficient to repay him for the little fruit they destroy, then must the rural walks of his neighbourhood lose their greatest charm, the sweetest and most delightful of nature's harmony.—*A Lover of Birds, The Aviaries, Cheltenham.*

The Blue Tom-tit.—Your correspondent "Dodman" may very easily rid himself of the presence of this destructive ravager among the fruit gardens, by a little artifice. He will require about three double trap-cages, such as are sold by bird-fanciers and wire-workers. In the lower part of each cage, place a Blue Tit as a call-bird, and bait the upper part with bruised hemp-seed, and a morsel of suet, or a meal-worm, pinned down on the moveable perch, which is supported by the elasticity of the spring-wire which forms part of the machinery of the cage. In less than a week, nearly every depredator may be secured.—*William Kidd, New Road, Hammersmith.*

Covering for Frames.—Seeing several complaints in the *Chronicle* about Whitney's composition for covering frames rotting the cotton, I beg to mention that I glazed some covers of hot-beds here this spring, with a composition of my own, which I found to answer the purpose quite well, and to admit light nearly equal to glass. After having stretched the cotton (very open coarse cotton) on the frames by means of small sprigs or tacks, I put on the composition with a soft clean painter's brush, giving two coats, one as soon as the other was dry. The mixture consists of ¾ of linseed oil boiled a little, ¼ spirit of turpentine put in and stirred well, and a little white rosin ground and boiled in the oil. I should suppose a little bees'-wax might also be of service; the worst of this composition is, that dust sometimes attaches itself on the outside of the covers or sashes when they are damp; however, a rub with a wet sponge cleans this off; the cotton is quite sound as yet, and does not admit one drop of water.—*A. W. Mushfoll.*

Dry-Rot in Timber.—No recipe for the prevention and cure of dry-rot having as yet appeared in the *Chronicle*, although a request for communications on this subject was made some months ago, I beg to refer to Sir Samuel Bentham's "Naval Papers," No. 6, p. 18, where he states—"I have known the impregnation of wood with sulphate of iron used as a preservative against and cure for dry-rot, as in the instance of the Negro-house mentioned in my Minute of the 13th Sept. last; and which impregnation I have understood to be very efficacious in that and some other instances." The timber of that Negro-house (in Jamaica) had been so prepared at the recommendation of Dr. George Fordyce; and I myself, about half a century ago, under the instructions of that gentleman, applied a solution of sulphate of iron to the frame of a window where dry-rot was making rapid progress, but which was effectually stopped by this application. He directed me to scoop out as much of the already-decayed wood as could be done without materially disfiguring the outer casing or paint, then to make a saturated solution—I put it up in a can of sulphate of iron in boiling water, and then directed to inject it with some little force into every part of the frame infected. After this, dry-rot made no further progress in the frame, or neighbouring wood-work. I may mention, too, that a large Oak beam, in a cellar at Wandsworth, was attacked by dry-rot, which was prevented from spreading by the same means.—*M. H.*

Acorus Calamus (or Sweet Flag).—This highly fragrant plant may be cultivated in abundance on rivers, ponds, or lakes. I have it growing in the river Lark, which bounds the Botanic Garden in this customer way; and although swans, ducks, and a variety of water-fowl frequent the stream, not a leaf is injured, while aquatics are totally destroyed. I am informed that ducks will feed on the Nymphæas, but that swans reject them; can anybody confirm this?—*N. S. H., Bury St. Edmunds.*

Cucumber Frames.—I understand that there is an ingenious ironmonger in the country who grows Melons and Cucumbers to perfection, by building a common brick-pit, with a false iron bottom, supporting the earth for the plants. Underneath this bottom he throws in, through a trap-door, the dung fresh from the stable, keeping up what heat he pleases. He scrapes out the spent dung from another trap-door. To me this an excellent plan to keep the dung out of sight in ordinary frames; and will it not preserve the heat more perfectly from its being guarded from the wet?—*Hortensis.* No doubt. A similar plan has been adopted.]

Wilmot's new Black Hamburgh Grape.—I hope that I shall not be thought presuming to doubt both your [not ours] and Mr. Mearns's opinion, that the Grapes lately exhibited at one of the Horticultural Society's meetings, as Wilmot's new Black Hamburgh, and described to be all indented as if beaten with a hammer, has any peculiarity different from well-grown Grapes of the common variety. Between 10 and 12 years ago, I paid a visit to the garden of a distinguished florist and Grape-grower at Norwich, and was much struck at seeing all his Black Hamburghs exactly resembling the description you gave of Wilmot's. Indeed I have often remarked a black Hamburgh under my own care, which was inarched on a stronger-growing Vine than itself (the Black Portugal I believe) produce fruit of the same description, while the parent Vine had its fruit perfectly round.—*J. M.* [Wilmot's is *not* Black Hamburgh, as we long since stated in a Leading Article.]

Gathering Pears.—I quite agree with the paragraph (p. 766), relative to "the moving of Peach-trees;" and in reply to the question asked by "Dodman," whether by the gathering of Pears at the time when the leaves change colour, the quality of the fruit be not impaired, I would say, that so far as I have had experience of their culture—and I have been a Pear-grower for the last 25 years, having 40 trees of different kinds trained against walls, some of which extend more than 40 feet—I have found it best to gather the fruit by the 10th or 12th of October. Perhaps in this cold and almost northern county, that time may be best for any aspect, either south, east, or west, to gather them, and quite late enough, the fruit then generally leaving the branch easily. I think the fruit can hardly acquire any additional valuable flavour from hanging on the trees longer, and the leaves at that time are almost a full green colour.—*Francis Darby, Colebrook Dale, Shropshire.*

Mealy-Bug.—Hereman's lotion destroys the Mealy-bug without injuring the foliage, if speedily washed off; but it is dear to buy, and dear to use. 1st. Because the contents of a 5*s.* bottle costs but 6*d.*, and will do but a few plants. 2d. Each insect or little coterie has to be touched with a camel-hair brush dipped in the lotion, and its use cannot be safely trusted to a boy. I think a boy at 1*s.* a day would, in two days, with a sponge and soap and water, destroy more bugs than a man in one day, at 5*s.* a day, with a 5*s.* bottle of lotion. 1*s.* 6*d.* a bottle for what is now charged 5*s.* would be ample, unless sent by post.—*Flora.*

Mignonette.—Possibly it may not be known to some, that Mignonette preserved in a house during winter, and turned out into the open ground in spring, will flower as freely as fresh plants, and at least a month earlier. I had, in boxes and pots, a few plants which flowered in the autumn of 1843, in a window having a northern aspect; they were turned out last spring, and are now in good condition.—*Paddy.* [Mignonette in its warm native country is a perennial, or rather an under shrub.]

Destroying Wasps and Bees.—In reply to Professor Henslow's queries respecting destroying wasps' nests, I beg to state that I lately dug out two nests about a week after they had a dose of turpentine, and found death and corruption begun in both. In a former Paper I advised the nests to be dug out and destroyed, but now I think, with Professor Henslow, that that operation may be dispensed with, provided the entrances to the nest are well closed, to keep in the fumes from the spirit. There is little doubt but that bees might be destroyed with turpentine, as mentioned by Professor Henslow, but not so quickly as by sulphur; waving the popular notion of pain or cruelty by the latter, still, where sudden death is intended, it is the best. By the former, the bees would meet a lingering death, and many would struggle and die in the cells, and must be picked out. The smell from both is bad, but perhaps that from turpentine lasts the longest. Smoke from sulphur is blamed for discolouring the cells; but the small quantity used can hardly affect them: they are rendered dark by the heat and traffic of the bees. Lately I observed such honeycombs in the shops in London, and was a little surprised to see so many bees squeezed amongst them, which showed the operation of killing the bees had been badly performed.—*J. Wighton.*

Calceolarias.—About this time of the year, what a miserable appearance do the generality of old plants possess, particularly if compared with the luxuriant foliage of seedlings! I therefore hope that the following remarks upon the treatment of Calceolarias after the blooming season may be acceptable to the cultivator of this favourite flower. If the old plants are to be saved, they must not be allowed to exhaust themselves by blooming too long; as soon as the flowers are past their best they should be cut off a few inches above the leaves, and the plants should be at once placed in a shady situation where the soil in the pots must not be allowed to become too dry. They should be examined occasionally and carefully, to see that ants are not establishing themselves in the pots, and for the purpose of removing all decayed leaves. Here they should remain until frost or snow makes it desirable to remove them into frames or into the greenhouse, where they should be watered very sparingly and with judgment, for if the soil becomes sodden the plants will soon damp off. About the turn of the year they will begin to move, and then is the time to break them up and to plant all the healthy pieces into small pots. These should be placed in a gentle bottom-heat, and care must be taken to keep the surface of the soil in the pots clear of Moss. The plants will soon begin to grow, and in a short time with the advancing season they will indicate, from their increasing size, the pots into which they require to be moved. I would recommend any one who possesses very favourite sorts to keep a small plant of each, and not to allow them to flower if he wishes to keep the bloom on his specimens to the last, or to obtain seed from them. Whilst upon the subject, I may mention my regret at the miserable prizes offered by the Horticultural Society for specimens of this favourite flower—for a dozen plants in 12s the first prize is 3*l.* 10*s.* I quite expect that they will disappear under this frigid treatment. No longer a grower or raiser of Calceolarias myself, I see with regret the fine old varieties of blotches and selfs giving way to spots and letters of the alphabet. The latter are very valuable as varieties, but if grown to the exclusion of the former it is to be regretted.—*Veritas.*

Gardeners' Benevolent Institution.—This Institution is objected to by some persons on the ground that its benefits are mostly restricted to the vicinity of London. The objectors say that a candidate living in a remote part of the country, however deserving he may be, has almost as much chance of becoming a pope as a pensioner; and, that there is some real or supposed difficulty in the way, is proved by the fact that applications for votes are very rarely received from destitute gardeners in the provinces. I have now before me letters from three applicants, all residing within a few miles of London, and I cannot at present call to mind more than two former candidates from a distant part of the country—one from Torquay, and the other from Carlisle; the last of whom has been twice in a minority. I mention this fact in order to draw to it the attention of the managers of the Institution, as I have reason to believe that the impression I allude to prevents some gardeners from supporting this useful Institution.—*J. B. Whiting.*

Walnuts.—I beg to call the attention of the public to the advantages of planting these ornamental and productive trees, the wood being very valuable. With regard to culture, sow the nuts in beds, which should be kept free from weeds, and at the end of three years plant finally 160 trees to the acre. Walnuts will grow in the poorest soil, and mixed with forest trees form good belts, &c. In the 10th year they will begin to bear, and taking the average produce per tree at only 1 bushel, the value of which is 10*s.*, they will give 80*l.* per annum for the acre; deduct 6*d.* per bushel for picking, and 2*l.* a-year rent for the land, and it will leave 54*l.* of clear profit. The expense of planting, first cost of seed, and every expense included, will be about 20*l.* per acre.—*Juglans.*

Miscellaneous.—*Mr. Charlton* observes, in reference to the destruction of small birds, that the Tom-tit, although much persecuted by gardeners, seldom does much mischief in a garden. On the contrary, he states that it effectually cleared his Pear-trees from brown scale without at all injuring the buds. He further remarks that blackbirds and thrushes are exceedingly useful for destroying insects; he says that he is a friend to small birds, which he considers to be of great service in a garden.

Societies.

LINNEAN SOCIETY.

Tuesday, Nov. 19th.—Robert Brown, Esq., in the chair. A collection of dried plants was presented through Mr. Joseph Janson. This collection was formed in Van Diemen's Land by Messrs. Milligan, Gunn, and Firlie, and presented by J. E. Bicheno, formerly Secretary of the Society, and now Colonial Secretary at Van Diemen's Land.—A Report was presented by Mr. Aaron Price, on the Timber-trees of Norfolk Island, accompanied with 20 specimens of woods. Some of these had a beautiful appearance, and were evidently well adapted for the various purposes to which wood is applied.—A stuffed specimen of the Iguana tuberculata, (Cuv.), from the Island of Grenada, in the West Indies, was presented by Mr. Alcard, F.L.S.—A collection of 300 specimens of dried plants, from the Tyrol, were presented by the Ferdinandean Society of Innsprück.—A Paper was read from Mr. Griffiths, on the Development of the Ovulum in a species of Osyris, in which he found that, like that of Santalum album, there was no cell or body in the sac of the embryo independent of the pollen tube. A second Paper was also read on the Development of the Ovulum in two species of Aviennia; the elongation of the sac is remarkable, and seems to be confined to those plants which have the same peculiar form of the free central placenta. The fecundation of the sac, in this instance, takes place only gelatinously. In this genus also, a protrusion of the reticulate end of the embryo, independent of the process of germination, took place. The observations made on the ovules of these plants were not such as to lead to the conclusion of the penetration of the pollen-tube, but were in favour of an influence being exerted by this agency.—Mr. T. S. Ralph exhibited a new species of the Linnæan genus Brachus, from Bombay, which was found inhabiting the seed of a leguminous plant.

CHISWICK SHOWS.

Morningside Practical Gardeners' Society, Nov. 5.—This was the last meeting for the season. The Prizes were awarded as follows:—*Chrysanthemums*: 1, Mr. J. Dowsett, gr., Cannon.

Bank, for Adventurer, Lauidum, Magnet, Mirabile, Queen, and Marquis; 3, Mr. T. Turner, for Globe. *Leeks*: Mr. J. Gourlay, jr., Bruntsfield House, for Musselburgh Flag. *Coleworts Greens*: Mr. T. Ovens, jr., Grange Bank. *Red Beet*: Mr. T. Ovens. *Carrots*: Mr. J. Downie, for Altringham. *Broccoli*: Mr. D. Swanie, jr., Ormsby Lodge, for Gillespie's Early. *Endive*: Mr. W. Ewen. *Celery*: Mr. J. Gourlay, for Sang's Eat-stemmed White. *Brussels Sprouts*: Mr. J. Downie. *Pears*: Mr. J. Douglas, for Citron des Carmes and Gansel's Bergamot. *Apples*: Mr. J. Douglas, for Ribstone Pippin, Golden Reinette, and Blenheim Pippin. AMATEURS'.—*Savoys and Leeks*: Mr. J. Steel, for Cape Savoy and Scotch Flag Leek. The Prize offered by Messrs. Dickson and Sons for the best *Red and White Celery* was won by Mr. Gourlay, with Sang's Eat-stemmed and Manchester Red. The Prize by the same for the *best Six Onions* was gained by Mr. J. Douglas with the Strasburgh. As a proof of the flourishing state of this Society, there were sent for competition 121 articles.

Hampshire Horticultural Society, Nov. 14.—This was the 20th Anniversary Meeting of this Society. The display of Chrysanthemums was good, particularly the Warden's and Mr. Ralfe's. The stove and greenhouse plants were but few. The fruit was fine, particularly Pears. Mr. Chandler, of Vauxhall, exhibited two trays of Chrysanthemum blooms, of superior quality. The Prizes were awarded as follows:—*Class* 1.—12 *Chrysanthemums*, in pots, four to the cast, S. G. Medal, Mr. Ralfe, for Queap, Reine de Prussi, Coronet, David, Achmet Bey, Mirabile, Repetens, Elitvina, Minerva, Duke de Cornegliano, De Crequi, and Madame Pompadour; 12 ditto, in pots, four to the cast, S. G. Medal, Rev. the Warden, for Mirabile, Formosum, Vesta, Duke de Cornegliano, Theresa, Madame Pompadour, De Crequi, Memnon, Minerva, Superb, Clustered Yellow, Campestroni, and Exquisite; 3 ditto, in pots, eight to the cast, Mr. Ralfe, for Incomparable, Princess Maria, Vesta, Memnon, Roseum, Gui Laborde, Duchesse de Montebello, Horatio, Horace, Princesse de Lamballe, Isoller, and Marie; 4 ditto, in pots, eight to the cast, the Warden, for Columbus, Duchesse de Montebello, Irene, Solon, Princesse de Lamballe, Orion, Coronet, Fleschier, Incomparable, Louis-Philippe, Marshal Augaine, and Bijou; 4 ditto, in pots, 16 to the cast, Mr. Wm. Barnes, for Mirabile, Formosum, Vesta, Duke de Cornegliano, Theresa, Madame Pompadour, Exquisite, Campestroni, Superb, Clustered Yellow, Minerva, De Crequi, Memnon, Princess Maria, Coronet, Grandee, Princesse de Lamballe, Marie, Grand Napoleon, Changeable Yellow, Queen, Incomparable, Beauty, Triumphant, and Adventurer.

NOTICES OF NEW PLANTS WHICH ARE EITHER USEFUL OR ORNAMENTAL.

SALVIA PRUNELLOIDES. Prunella-like Sage. (*Hardy Perennial*). Labiatæ. Diandria Monogynia.—Of the many Salvias described in botanical works, there is decidedly a preponderance of species with flowers of a cerulean tint. Some of these now hold a deservedly eminent station amongst the summer-garden decorations, and we are glad to be enabled to give pre-minence to another, which, although it has been known in nurseries since 1840, is rarely seen beyond their precincts. The comparative obscurity in which it has been fated to continue, may perhaps be traced to the introduction about the same time of the more showy Salvia patens, the magnitude and superior loveliness of the flowers of that species having completely engrossed the attention of cultivators in the desire so universally manifested to possess it, to the almost entire exclusion of all less-favoured competitors. In its habit of growth S. prunelloides is unexceptionable. The stems are produced closely, without appearing crowded, and rarely grow more than a few inches high, when planted in a border. The foliage is of that happy medium size, which has neither the coarseness of some of the larger-growing species, nor yet the scantiness of many of the smaller kinds. The plant spreads by means of underground stems, which develope shoots with great rapidity, that soon acquire a flower-bearing maturity; and though the blossoms, individually, are rather minute, yet, when a number of flower-stems (rarely more than 8 or 10 inches long) are borne in close proximity, they produce an effect decidedly ornamental. For some time it was a matter of doubt whether it would endure the severity of our climate without protection during winter. We are, however, enabled to state its perfect hardiness, plants having stood without the slightest protection for three successive winters, in the nursery of Mr. Bunney, at Stratford. It ought to be planted in a well-drained and airy situation; and, unless the soil is tolerably nutritive, the flowers will be much inferior in size. A hardy plant, with bright-blue flowers, to contrast with Verbenas, &c., in the parterre, must be useful. We believe the merit of raising and flowering the first plants in this country, is due to Mr. Moyes, of Durdham Down Nursery, Bristol, who received roots from Mexico. Humboldt and Bonpland met with it on the volcanic mountain of Jorullo, where it grows in rocky situations: it has also been found in New Spain, by Mocino and Lesse, and in various parts of Mexico, by different individuals.—*Paxton's Magazine of Botany.*

ABUTILON VITIFOLIUM. Vine-leaved Abutilon. (*Greenhouse Shrub*). Malvaceæ. Monadelphia polyandria.—This fine Malvaceous plant is a native of Chili, whence it appears to have been introduced about the year 1836, by Captain Cottingham of Dublin. It was noticed in this work in July 1840, when it was stated that it had proved quite hardy in Ireland, having stood in a south border, without protection for three years. Under such circumstances it must be a noble looking shrub, for it is said to maintain a stature of 6 feet, and to become one mass of blossom. With us in England it does not, however, prove fit for the open ground. It may be grown in a large pot or tub, but where it can be planted out in a conservatory bed it will succeed much better. The soil most suitable is heath-mould mixed with silver sand. Being a greenhouse plant, air should be given at all times when the weather is favourable, and it must be exposed as much to the light as possible. It is propagated from cuttings in the usual way. The worst of the plant is, that it occupies a great deal of room, and therefore can only be grown in large houses, and it is, like all its family, a favourite resort of red-spider. When, however, the first is of no consequence, and the second can be kept down, it is well worth growing; for we have few plants whose flowers form such broad gay masses.—*Botanical Register.*

THUNBERGIA ERECTA. Erect Thunbergia. (*Climbing Evergreen.*) Acanthaceæ. Didynamia Angiospermia.—Charming as most of the Thunbergias are, the superiority of this species must at once be admitted by every beholder; for the beautiful variety of tint exhibited in its large blossoms fully entitles it to the first rank in the genus. It was discovered by Mr. Whitfield in the interior of Sierra Leone, who, as we learn from the "Botanical Magazine," at considerable danger and risk succeeded in securing specimens, which he brought safely to England, to the gardens of the Earl of Derby, at Knowsley Hall, near Prescot, Lancashire, from whence it has already been dispersed throughout many parts of the country, and now exists in most extensive nursery establishments in the kingdom. When supplied with a very warm and humid atmosphere and planted in a large pot, it grows very exuberantly, and will soon extend its shoots to many feet in length. But if kept in an airy, cool place, it loses its rambling climbing habit, and assumes more of the character of an ordinary erect-growing shrub, and is less profuse of its flowers. In the nursery of Mr. Knight, King's-road, Chelsea, a fine specimen was placed over a tank in a propagating house, and was, doubtless, greatly assisted by the degree of bottom-heat with which it was favoured, in forming the numerous flowers which appeared all along the shoots. No doubt a close pit or frame in which a little heat can be kept up, in conjunction with a suitably moist air, will be the very best place for exciting it to the desired freedom of growth. A rich soil, a well-drained and roomy pot, together with copious waterings during active growth, are also conditions by which success is greatly influenced. And to ward off the pestiferous attacks of the red-spider, which determinedly infest all this tribe of plants when-ever attention loiters, the syringe should be frequently brought into requisition, applying the water well to the under surface of the leaves. Cuttings take root with the most perfect readiness, and by their removal confer an immense advantage on young plants, particularly when large specimens are wanted; for an increased number of shoots will be produced, and what is lost in time by retarding the blooming of the plant, will be gained in ultimate effect. The bright golden eye in the centre of the flower, surrounded by a field of blue and violet, being the most striking feature of the species, has been very aptly chosen as the foundation of the distinguishing specific term.—*Paxton's Magazine of Botany.*

Garden Memoranda.

The Dublin Botanic Garden, Nov. 1844.—The following is an abstract of the Second Annual Report on the state of this Garden to the Botanical Committee and Members of the Royal Dublin Society, by the curator, Mr. Moore:—The incongruity, he says, which has so long existed between the plant-houses here and the Garden generally, is now being done away with, and owing to the able manner in which the efforts made last year have been carried into effect, one wing of a new range of conservatories has been erected, on the newest and most approved principle, being commodious, handsome, and in keeping with the exterior of the Garden; and there is every certainty of a much larger portion being immediately built, Government having generously voted a sum for that purpose. It is also stated, that the increasing interest taken by the public in this establishment shows that they duly appreciate the improvements going forward; this is manifest from the greater number of donations of seeds from friends, both at home and abroad, and also by the prevailing classes who visit the Garden. It may be here mentioned that, owing to the great facilities now afforded for the transmission of seeds, &c., in small parcels, through the Post-office, instances have occurred this season of seeds being collected from plants growing at Meerut, and other parts of the East Indies, sent home by the overland mail, sown and vegetated in the hothouses within nine weeks from the time they were collected. The new house has been recently filled with plants, which show to good advantage, affording, at the same time, the means for visitors to examine such of them as they may desire, with ease; which is of great importance in a public garden. The whole of the arrangements of hardy exotic plants are being removed, re-arranged, and condensed, in order to make room for the British plants, which now occupy a site assigned for new buildings. In the Arboretum, many of the trees which have been recently added, natives of the Mexican and Himalayan mountains, as well as of other parts of the world, are now beginning to establish themselves, and prove their suitableness for the climate of Ireland, particularly the Coniferous or Pine family, which have of late years become such great *desiderata* among planters. The experience of two winters enables Mr. Moore, with a considerable degree of certainty, to state, that the following species, natives of Mexico, will prove sufficiently hardy for most parts of Ireland, viz., Pinus Montezumæ, Pinus Teocote, Pinus Apulcensis, Pinus Hartwegii, Pinus patula, and Pinus macrophylla. The Pinus Russelliana and Abies religiosa (two beautiful species, also natives of Mexico), were cut up considerably with frost, although slightly protected; still it is expected that they will prove nearly hardy when once well established, particularly in the southern counties; and should this be the case, the latter will be a most interesting addition, being one of the most beautiful of the tribe, attaining to a great size on the Mexican mountains, at an elevation of from 7000 to 9000 feet. Some of the fine species from the N. W. coast of America are offering to do well, such as Pinus ponderosa, Pinus Sabini, Pinus Coulteri, Abies nobilis, and Abies amabilis; but those which appear of greatest importance are some of the Himalayan species, Abies deodara, Pinus excelsa, and Abies morinda, which are both ornamental and very valuable trees. The experiments which have been made at this place with artificial manures have been mostly with a view of following up those of last year, which were as extensively made as means permitted, and the result proved, beyond the slightest doubt, that the mixtures called Murray's Fertilizers, and guano, produced the desired effect for one season at least; but that part of the experiment, not the least interesting, remained to be proved, whether a subsequent crop would be benefited by those stimulating substances, or whether the whole of the fertilising powers were spent on the first crop. With a view of endeavouring to prove this, the ground which was experimented on last season with a Potato crop was sown down with Wheat after the Potatoes were dug, which showed very little differences as the crop progressed towards maturity, though that sown on the portions where the fertilising mixtures were, vegetated sooner, and continued stronger through the winter than that on the stable manure, but the latter appeared to overtake and even surpass it as the summer advanced. The portions of Grass-land which were top-dressed with the fertilisers on the previous year, showed very little difference from the adjoining parts, which got no manure of any kind. The inference, therefore, to be drawn from these experiments is, that most, if not all the fertilising effects are given off during the year the substances are supplied to the soil; but there are so many things to be considered along with the manner in which matters act on soil, that isolated, imperfect experiments prove little or nothing. In conclusion, it is added that, if the important improvements now projected are carried out, this establishment will be worthy of the country, and highly creditable to the Royal Dublin Society, as well as to every person connected with it.

Miscellaneous.

New Zealand.—The specimens of New Zealand woods which are now being exhibited at the Company's offices in Broad-street, City, are of an entirely novel and beautiful description. Several articles of decorative furniture have been made by M. Levrin, the importer, to show the great superiority of those woods over all others hitherto used by the cabinet-maker of this country. When they become more generally known, we have no doubt they will be used for drawing-room furniture, as we understand the New Zealand Company intend to import their woods on a large scale, and which must become the source of great advantage to the colony.—*The Times.*

China.—We are happy to state that Mr. Fortune's mission for the Horticultural Society proceeds very favourably. His last letters are dated, Shanghae, June; and it appears that the objects of his mission are likely to be entirely fulfilled. He had collected many very fine things, some Azaleas, and Moutans, several handsome shrubs, and a beautiful, hardy, evergreen tree, supposed to be Cryptomeria japonica. The Chinese were obliging and accessible, and he had *actually been present in the Green-Tea country about Ningpo in the midst of the gathering season.* Mr. Fortune had received the greatest assistance from Her Majesty's Consuls, Capt. Balfour at Shanghae, Mr. Thom at Ningpo, and Mr. Lay at Canton. He had also received valuable aid from Lieut. Shadwell and Dr. Maxwell, and from Dr. Lockhart and Mr. Medhurst, of the Missionary Society.

CALENDAR OF OPERATIONS

For the ensuing Week.

I.—HOTHOUSE, CONSERVATORIES, &c.

STAPHODEA campanulata, and Clerodendron splendens, two plants from a very hot climate on the west coast of Africa, near the equator—where, also, Napoleona imperialis is found—form a striking example of how we may be deceived in our treatment of stove plants of whose habits we know only that they are from such and such a country: the former we treat as a stove plant, yet it is so hardy that it will grow just as well in the open air from the end of May to the latter part of September, and then it may be wintered in the conservatory if kept rather dry; the Clerodendron splendens prefers a cool, shady part of the stove, and is better fitted for an intermediate house, but it will grow freely in a good conservatory if not allowed much light, which is disagreeable to it when growing. There can be little doubt but that many other stove plants will prove sufficiently hardy to do in the conservatory, and this is the best time to begin the experiment. Look out duplicates, and place them by themselves, to be kept dryer through the winter than the rest of the collection; they should also be placed in the coolest end of the house.

Conservatory.—The earliest of the Chrysanthemums will now be nearly over, and when they are turned out the best way is not to cut them down, as is generally done, but to store them in light dry soil, under a west wall, turned out of the pots; the tops being left on will keep the suckers more backward, and also shelter them in some degree: the less the suckers grow before March the better plants they will make next year. Spring-forced Camellias now in bloom should be guarded against currents of cold air and damp. Cineraries, which are great ornaments for this house in winter, are thirsty plants, and good subjects on which to try experiments with some of the new fertilisers mixed in the water given them, they are also liable to the attacks of insects, and unless they are looked after they will soon establish these among other plants. The fine large varieties of the Chinese Primrose, although they grow well near the glass, do best in shaded places where the sun cannot reach them; two parts rough leaf-mould, and one of very old cow-dung, with a little sand, is the best compost for them, and in this they like plenty of moisture. Besides the double white and double pink, which are very showy at this season, there are some of all shades, from pure white to very dark purple, some with fringed edges, which look gay; but florists are discarding this class for smooth entire edged ones, of good substance, size, and colour; and probably the pin-eyed ones will not be thought much of now that they are become florists' flowers.

Pits.—Half-hardy plants stored away in winter in pits and temporary structures, are likely to have a severe trial before the winter is over. Prepare against severe weather with additional coverings. Keep such plants as dry as they can bear, and expose them on every favourable day.—*D. B.*

II.—FLOWER-GARDEN AND SHRUBBERIES.

Out-Door Department.

As the leaves are now all in a great measure off the trees, the pruning of common shrubs may be proceeded with, and the borders put in order for the season. I have previously spoken against digging; and as the ground must be cleared of leaves, it is best, where they are not wanted for other purposes, to draw them into ridges in the back part of the shrubbery, and there to let them lay and rot, to be distributed over the ground about this time twelve months. It is not a bad plan to fill holes intended for American or other choice plants with wet leaves, and to place the ball level with the surface of the ground: as the leaves decay the plant will sink to its proper level, and grow admirably.

Pits and Frames.—Look sharply to the protection of these structures, as the frost in November is a pretty good earnest of a severe winter. Keep the plants as dry as possible; and if the atmosphere is damp, it is not a bad plan to dry it a little, by placing a pan or two of burning charcoal in the pits, at the same time giving plenty of air. This should be done on a dry day.—*W. P. A.*

III.—FLORISTS' FLOWERS.

Polyanthuses.—Are throwing up a great number of autumnal blooms this season. The variety called Hutton's Lord Rancliff, a remarkably hardy as well as a pretty sort, appears more disposed to bloom late than older varieties. I have noticed that on beds where the plants have all been divided at the same period, and the roots healthy and doing well, that two-thirds of this sort flower, whilst not one in ten of such varieties as Cadwallader's Invincible, Tantarara, Alexander, Fletcher's Desdemona, Read's Telegraph, Martin's Prince William Henry (red), &c. &c., which are much older, throw up a bloom. These last mentioned sorts must have their autumnal blooms removed, but the other (Lord Rancliff) is so luxuriant, and so extremely robust, that it appears to make not the slightest difference, as I have had them blooming profusely till Christmas, and also have had flowers at the proper season able to compete with the best of my neighbour's. *Auriculas.*—Must continue to have every attention; water very sparingly, and remove all dead leaves. When opportunity offers, procure a supply of willow dust, which is a most excellent ingredient in Auricula compost. *Tulips.*—The recurrence of fine weather will give opportunities for all Tulips to be planted, as they are now suffering much if

kept out of the ground; for frost around the tubers is good. *Carnations*—Must be occasionally watered, but at this time sparingly; remove decayed leaves, or those which are affected with the "black spot," and be particular that dirt or other extraneous matter is removed from the axils of the leaves. We hear that the finished blooms exhibited lately, many of which were raised young at the Coppice Show, near Nottingham, on the 6th of August last, has been sold to a Florist of Staffordshire. Fifty dollars were taken at 10s. 6d. per pair; we trust that the flower has been sold "with all its engagements," since the considerable disappointment would be lessened.

Pinks.—The beds must be kept free from weeds, and should frost occur they must be looked over, and the plants pressed down, or fastened, as they are apt to be raised out of the ground, especially if planted late.—*J. M.-M.*

IV.—PINERIES, VINERIES, &c.

Pineries.—There has been such a variety of methods recommended (each as the best) for the cultivation of the Pine-apple, that it has become rather a difficult task to decide which really has the best claim to that title. For my own part, I neither know I have become a convert to what is called "Hamilton's system;" and for the following reasons: first, because the treatment is remarkably simple; and second, because a greater weight of fruit may be obtained in a given space, and at a much less expense, than by any other method known to me would pit system required, which is in itself a great recommendation to amateurs who may take a fancy to Pine growing. I do not know Mr. Hamilton, nor have I ever seen his Treatise, but I know that one of the most successful exhibitors of Pines at Chiswick has grown them on this plan for years, and wherever I have seen the same plan in operation, I have been struck with the excellence of the fruit, and the comparative small size of the plants. This may seem a departure from the objects of a Calendar; but as beginners in Pine-growing, as in other things, are often puzzled to know which method to adopt, a disinterested opinion on a mode of culture of which all have heard, but of which few have had an opportunity of judging for themselves, may not be out of place here.

Vineries.—In regulating the temperature of Vineries recently shut up, regard must be had to the external atmosphere. In mild weather the day temperature may be 65° by fire-heat, and if the sun raises the thermometer 10° or 15°, so much the better, as the fire need not then be made till late in the evening, if needed at all. It is not necessary to maintain a heat of 50° on cold nights; during frost or cold winds, 45° by night will be sufficient till the buds begin to swell. The late house should be kept at 45° or 50° by night, while the fruit lasts. It is better to keep the lights closed during the day in close, hazy weather, in order to keep the damp out of the house.

Peach-houses.—The directions given for the temperature of the Vineries this week, will apply equally well to the Peach-house started last week. It is not uncommon to see air admitted whenever the sun shines on a house just commenced forcing. This is unnecessary, as, if the trees are frequently sprinkled with the syringe at this season, a day's sunshine is more beneficial in exciting the buds than a week's firing without sunshine.—*G. F.*

V.—HARDY FRUIT AND KITCHEN-GARDEN.

Peach-trees.—If the present frost should be likely to continue, those who had, that the leaves of their Peach-trees are still in a green adhesive state had better protect the trees slightly by straw-ropes netting or hanging Fern, &c. among the branches, as a sudden check to the growing system after such mild weather would be more prejudicial now than after the trees had got accustomed to variations of temperature.—*D.*

Radishes, Small Salading, Asparagus, Lettuce, Cauliflower, &c. will be quite safe where they are in pits or frames, as there is little difficulty in keeping them from frost in such circumstances. Although we do not yet expect much severe weather, no time should be lost in securing plenty of Radish, Cauliflower of the June and July sowing, &c. to be protected with straw or reed covers in rat pits, &c. I may here repeat my method of making these covers:—Take three slips of wood, from 2 to 3 inches broad, and from one half to three quarters of an inch thick, according to the intended length and width of the cover; cut two pieces for the sides of the cover, at the distance of from 2 to 3 feet apart, and the third one in the middle between them; cut pieces of wood of similar thickness across the two ends, and in the intervening space use lighter wood at the distances of from 1 foot to 14 foot apart; then the frame of wood thus formed, and fill it neatly with reeds or straw to the thickness of the three longitudinal pieces; then nail slips of wood, opposite to those on the other side; and the ends of the straw, and the cover is fit either for turf pits or glass frames. Using lighter wood for the cross pieces in the middle, is for the purpose of causing less strain to be placed on the twine that pieces when meeting the covers, and also for rendering them lighter. I prefer Wheat-straw to reeds, as being less expensive and not so liable to break when exposed to frost and wet alternately, but the straw ought to be drawn before the crop is threshed, and all the dark cut off, otherwise it will be broken by the flail or machine, and the ears will not only act as a sponge for retaining moisture, but will offer an inducement to birds to pick your covers to pieces. Such covers are not quite so effectual in excluding rain, as painted canvas, glazed cover, &c.; but they are a valuable protection from frost, where inexpensive straw is to be had, and afford a means of employment to labourers in unfavourable weather.—*Sea Kale and Rhubarb.*—We have had a good supply of the former from the beginning of the month, by adding fermenting materials as previously recommended. The most economical method of growing the latter, is to sow every year, and take up and force it in a similar manner. Those who depend on beds out of doors for a first supply, must examine the state of their respective beds, to see that it is not getting overheated; nothing is better than tree leaves alone. Those who desire a tolerably early supply with little trouble, should cover their beds with any litter they can procure, so as to prevent the escape of the heat now existing in the soil.—*Roulins.*—Clear and attend to Mushroom-beds in succession; your asparagus-frames. Protect the roots of globe Artichokes for the winter; earth up Celery when dry, and dig, trench, or ridge all vacant ground.—*R. W.*

VI.—COTTAGE GARDENING.
